Because the renal threshold for glucose occasionally increases during pregnancy and because the degree and onset of lactosuria is so variable, simultaneous determination of blood and urinary glucose on several occasions during pregnancy may prove useful in management. In addition, the physician should realize that the "stick" tests (Tes-Tape, Clinistix, Uristix, and the like) are semiquantitative glucose oxidase tests, whereas the Clinitest tablet is a modified Benedict copper-reduction test. The Clinitest tablet, while providing more quantitative measurement of reducing substances, is not specific for glucose.

Ketonuria

Most authors recommend daily testing of fractional urines for both glucose and acetones. Pedowitz and Shlevin[5] stress the need for the patient to report any persistent or progressive ketonuria. This is understandable in view of the previously mentioned effect of acidosis and coma on the perinatal mortality. Conversely, hypoglycemia, according to Kyle,[2] does not seem to affect fetal survival adversely. He suggests that this finding may be accounted for by the relative impermeability of the placenta to insulin, by the remarkable tolerance of the fetus to hypoglycemia, by the capacity of the fetal liver to respond to hypoglycemia, or by a combination of these factors.

Blood Glucose

To determine necessary changes in insulin requirements, Carrington[7] employs fasting blood-glucose values. Kyle[2] and several other authors prefer to base insulin requirements on the 2-hour postprandial true glucose values and attempt to maintain this level at 120 mg. per 100 ml. of blood or less. Kyle suggests that this determination be made at each visit. In addition, he suggests that a 24-hour quantitative glucose determination be made at frequent intervals and an attempt be made to limit glycosuria to 5 to 10% of the available carbohydrate intake. When a daily urinary loss of 20 gm. or more of glucose is observed in the absence of hyperglycemia, he suggests a dietary supplement that corresponds to the amount of carbohydrate lost.

Although it is true that several authors have reported no correlation between fetal survival and maternal blood-glucose levels per se, it is also true that the management program of Given and associates,[10] which allows only symptomatic control while employing management otherwise similar to that practiced by most teams, resulted in a fetal loss of 20% in viable infants of diabetic mothers. Furthermore, many authors have reported a lower incidence of large infants born to diabetic mothers in whom chemical, rather than symptomatic, control was maintained.

Diuretics

If salt restriction alone proves inadequate in controlling edema, diuretics should be used. Chlorothiazide and hydrochlorothiazide have the advantage of having proved their therapeutic effectiveness. Carrington[7] recommends that thiazides or ammonium chloride be given for three-day periods, with a three-day omission of drug administration between each period. Driscoll and Gillespie[11] use up to 200 mg. of hydrocholorothiazide daily (divided doses), and, if necessary, give 2-ml. injections of meralluride (Mercuhydrin) once or twice weekly. With the thiazides, supplementary use of potassium may be necessary and electrolyte levels should be checked frequently. The reported hyperglycemic effect of thiazide derivatives has not proved a significant problem in maintaining rigid control of the diabetes.

The effect of diuretics on the severity of hydramnios is controversial. White[12] believed that the use of diuretics decreases the severity, but not the incidence of this complication — which is increased in diabetics.

Hormonal Therapy

The use of estrogens and progestins as adjunctive therapy remains highly controversial. The Joslin Clinic group has employed hormonal therapy extensively and reported a perinatal mortality rate of 9[11] to 13%[13] when hormonal therapy was employed as part of the diabetic management program. The main argument against its use is that comparable perinatal mortality rates are attained by others who do not employ hormonal therapy. In fairness to White and her group, it should be pointed out that the Joslin Clinic group has included in their series a much higher proportion of severe diabetics than have the other groups. White has stated the belief that her program of hormonal therapy reduces that incidence of spontaneous abortion, premature labor, toxemia, and severe hydramnios.

It is a widely held belief that the enviable fetal salvage attained by the Joslin Clinic

Continued

creased fetal survival. Driscoll and Gillespie[11] stressed restriction of activity for patients with renal disease.

Timing of Delivery

Timing of delivery is one of the most important, and often the most difficult, of the obstetric decisions in the management of the frankly diabetic patient.

Prior to Term

There is general agreement that these patients should be delivered prior to term. However, there is disagreement and literary confusion regarding the specific optimal time for delivery of the well-controlled, frank diabetic who is free from other complications. Some authors[3,4,7] have recommended delivery from the thirty-fifth through the thirty-seventh week, whereas others[5,14] have suggested 18 to 24 days prior to term. Driscoll and Gillespie[11] stated time of delivery more specifically according to classification: by the end of the thirty-seventh week for class B; between the thirty-sixth and thirty-seventh weeks for class C; and individualization for classes D and E since a favorable prognosis for this group is poor after the thirty-sixth week.

It must be stressed that, in any decision regarding the date of delivery for the individual patient, many factors other than the above-mentioned range of dates must be considered, because these guidelines simply represent the period in gestation in which various authors have obtained greatest salvage. Therefore, timing of delivery per se cannot be held solely responsible for the fetal salvage attained during the above-mentioned periods.

Choice of Delivery Date

Since various authors have reported fetal salvage of from 82 to 92% when using preferred dates of delivery that have ranged from approximately 18 to 35 days prior to the expected date of confinement, it would seem wise to anticipate delivery of the individual patient during this period. The choice of the *exact* date should be determined after full evaluation of the following factors.

1. Delivery prior to the thirty-second week is accompanied by a neonatal loss of more than 50% because of prematurity.[3]

2. Postponement of delivery until after the thirty-seventh week will result in a stillbirth loss in excess of 25%.[3]

3. The degree of diabetic control after repeated bouts of ketoacidosis is associated with an increased incidence of perinatal death. The presence of recurrent ketoacidosis should influence one to advance the date of delivery.

4. Presence and severity of complications should be considered. Kyle[2] stated that "although toxemia is generally accepted as an indication for prompt interruption in the thirty-fifth week, Given . . . does not temporize even at the thirty-fourth week." Similarly, marked hydramnios is considered by many to be an indication for early delivery. The presence of progressive renal failure or advancing retinitis influences one to deliver early. Purely obstetric indications — such as third trimester bleeding — may occur, and these must be individually evaluated and managed according to sound obstetric judgement.

5. Fetal size and age should be considered. The entire discussion of timing of delivery assumes that fetal age is known. Such an assumption is necessary but is risky, as virtually all large series mention instances in which errors were made in determining fetal age — often with disastrous consequences. Errors are made in both directions, that of over-estimating fetal age seemingly being the more common and, of course, leading to the delivery of "too premature" infants. It is for this reason that the obstetrician must, from the time of the initial history and physical examination until delivery, secure and record every possible bit of information that may aid in accurately determining fetal age. Means of arriving at this determination have been stressed previously. Although its value has been questioned, a lateral abdominal roentgenogram that shows ossification centers in the distal femoral epiphyses is comforting to most obstetricians. In addition, congenital abnormalities that might influence the mode of delivery are occasion-

ally discovered. Failure to visualize the epiphysis does not unequivocably prove immaturity.

Good correlation has been reported between fetal survival and birth weights between six and eight pounds in infants of diabetic mothers. In any attempt to deliver infants of this size, the presence of a small fetus in the absence of evidence of placental insufficiency indicates relatively later delivery. Excessive fetal size indicates relatively earlier delivery.

6. Previous obstetric history would seem to be of relatively less importance than most other considerations — especially if diabetic control in the present pregnancy has been good.

7. Determinations of estriol in the urine may become a valuable aid in determining the date of delivery. Greene and Touchstone[15] reported the results of urinary-estriol excretion in 35 pregnant diabetics. Of the 35 patients, 10 had 24-hour urinary excretion of estriol determined daily, seven had such determinations done three times weekly, eight had them done once weekly, and 10 patients had single determinations made. For 19 of the patients the 24-hour urinary-estriol excretion was more than 12.0 mg. and no perinatal difficulty was encountered. Of the remaining 16 patients, four with perinatal difficulties had levels below 4.0 mg. per 24 hours and their infants died, whereas 12 had levels between 4.0 and 12.0 mg. per 24 hours and their infants survived.

Value of Estriol Determination

Serial urinary-estriol determinations appear to be of particular value in cases of suspected placental insufficiency. Such determinations may prove useful in cases in which, for various reasons, the obstetrician encounters unusual difficulty in weighing the risks of fetal jeopardy in utero against those of infant prematurity.

In an assessment of significance of urinary-estriol levels, the following should be remembered: (1) The levels are not a reliable index of placental function in cases of erythroblastosis;[11] (2) acute urinary-tract infection, especially pyelonephritis, is accompanied by low estriol levels;[16] (3) mandelamine may render estriol undetectable by some laboratory methods;[15] and (4) the glucuronidase method, rather than the acid-hydrolysis method, of urinary estriol determination should be used for diabetics because of a tendency toward falsely low values reported in urine that contains glucose when the latter method is used.[16]

Mode of Delivery

Although labor may begin spontaneously, usually the obstetrician must choose between cesarean section and induction of labor in terminating the pregnancy. If induction is chosen, it may be either medical or surgical or a combination of both. In any event, the physician must decide the circumstances under which he will interrupt either spontaneous or induced labor by cesarean section.

Induced Trial

In discussing induction of labor, Driscoll and Gillespie[11] have stated, "In all instances it is necessary that productive labor ensue within six hours following amniotomy and/or oxytocin induction. After a maximum of eight to ten hours of labor, delivery should be imminent and an easy low forceps delivery anticipated."

Cesarean Section

They consider cesarean section to be indicated when the above criteria are not fulfilled. In addition, they consider previous cesarean section, previous difficult pelvic delivery, fetal distress, abnormal presentation (including breech), and E and F classifications as indications for section.

The analysis by Gellis and Hsia[3] of the relationship of mode of delivery and perinatal mortality indicates that good results may generally be obtained by either the abdominal or vaginal route when proper indications for each method of delivery are observed. Different authors have different opinions as to what may consititute these "proper indications."

Vaginal Delivery

In general, vaginal delivery is reserved for well-controlled diabetics who have minimal or no other complications, in whom the vertex presents and no disproportion exists,

Continued

and in whom an "atraumatic," reasonably rapid, uncomplicated delivery may be expected.

Also in general, best results seem to be obtained when indications for induction are strict and those for cesarean section are liberal.

Prolonged labor or traumatic delivery (or both) is tolerated very poorly by infants of diabetic mothers. Midforceps and breech deliveries are accompanied by excessive neonatal morality, and mortality rates in excess of 70% have been reported in breech delivery of viable infants.

Predelivery Management

Predelivery hospitalization has been previously mentioned.

Insulin

Each internist seems to have his own dosage schedule of insulin for the immediate pre-partum and postpartum periods. Some employ only regular insulin during this period, whereas others prefer partial replacement with NPH or Lente and employ regular insulin for fine adjustments. Most give a reduced dose of insulin on the day of delivery, the reduction usually being greater in patients slated for section than in those for whom vaginal delivery is planned. A postpartum decrease in insulin requirement is anticipated. In most instances a return to insulin requirements that were used before delivery is expected, but requirements may prove to be greater or less than prepregnancy requirements.

Anesthesia and Analgesia

In deciding on premedication and type of anesthesia both obstetrician and anesthesiologist must keep in mind the need to regard the fetus as premature regardless of size or weight.

A parasympatholytic drug such as atropine in a 0.4-mg. dose should be given about one hour prior to anticipated delivery.

Analgesic agents should not be used prior to elective cesarean section, and dosage should be kept to a minimum if such agents are used prior to vaginal delivery. Hartridge[17] recommends that only small dosages be used when narcotics are necessary. She recommends 50 mg. of meperidine (Demerol) or 30 mg. of alphaprodine (Nisentil) and states that nalorphine (Nalline) or levallorphan tartrate (Lorfan) should be given 15 to 20 minutes prior to delivery if the above narcotics have been given less than two hours prior to delivery.

The use of local field block for cesarean section and pudendal block for vaginal delivery theoretically results in the least possible disturbance of fetal physiology. However, in the hands of skilled anesthesiologists, spinal, caudal, or general anesthesia has been employed and the results have been statistically comparable.

Summary

Management factors responsible for improved maternal and perinatal mortality in cases of coexistent diabetes and pregnancy have been discussed and the importance of the following factors stressed: (1) meticulous prenatal care by an experienced team that includes obstetrician, internist, pediatrician, and patient; (2) rigid chemical control of the diabetes beginning early in pregnancy; (3) frequent prenatal visits for early recognition and aggressive treatment of complications; (4) control of fluid balance to decrease the incidence of toxemia and degree of hydramnios; (5) ante-partum hospitalization; (6) delivery from 18 to 35 days prior to term; and (7) treatment of the newborn as premature regardless of weight.

Grand Rounds

Primary Aldosteronism

JEAN R. ECKERLY, M.D.
Minneapolis, Minnesota

SINCE 1954 and Conn's description of a case of aldosterone excess caused by an autogenously functioning tumor of the adrenal cortex,[1] primary aldosteronism has been a recognized, curable cause of hypertension. During the intervening years aldosterone excess has been demonstrated in a variety of clinical entities, including edematous states, sodium deficiency syndrome, and cases of hypertension in which no adrenal tumor was demonstrable. Thus, some confusion about the significance of aldosterone excess arose and probably dampened the clinician's interest in searching for cases of primary aldosteronism.

However, with clarification of the renin-angiotensin-aldosterone regulatory mechanism, it now appears to be possible to separate these clinical entities.[2] Indeed, it is through measurement of renin levels that Conn has described subclinical cases of primary aldosteronism[3] and has suggested that this condition may be present in 20 per cent or more of hypertensive patients.[4,5] This interesting and provocative suggestion has prompted new interest in this syndrome.

The purpose of this paper is to outline the present concepts of the renin-angiotensin-aldosterone system by briefly reviewing the data which led to its description as a physiologic regulatory mechanism. Finally, the syndrome of primary aldosteronism, its possible prevalence, and diagnostic considerations will be discussed.

Renin-Angiotensin

Renin, an active principle in crude kidney extract, which will produce hypertension, has been known since the turn of the century.[6] It was

---

*Medical Grand Rounds, Hennepin County General Hospital, March 1, 1966.

Continued

shown by Page and Helmer along with Houssay and Braun-Merendez that renin is a proteolytic enzyme which acts upon a plasma precursor to yield a potent vasopressor.[7] There is good evidence that renin is produced by cells in the juxtaglomerular apparatus of the kidney.[8] Renin converts angiotensinogen (an alpha-2-globulin produced in the liver) to angiotensin I, a decapeptide. Angiotensin I is converted by an enzyme present in the plasma to angiotensin II, an octapeptide.[9] Angiotensin II is a very potent vasopressor and was at one time thought to have sodium-retaining properties. It should be understood that any action ascribed to renin is actually mediated through angiotensin II.

Aldosterone

Desoxycorticosterone, the life-saving factor for the Addisonian, was synthesized by Reichstein in 1938. The search for the naturally occurring sodium-retaining steroid of the adrenal cortex culminated in 1954 when Simpson, Tait, Reichstein, Wettstein and Nehrer isolated 18-oxo-corticosterone, later named aldosterone.[6] Desoxycorticosterone and aldosterone both[10] increase the exchange of potassium for sodium in the distal renal tubule, the sweat glands, and the salivary glands. An excess of either of these substances will produce sodium retention to such an extent that plasma volume increases, potassium deficiency and alkalosis ensue, and hypertension develops.[6] A steroid analogue of these hormones, spironolactone, will competitively inhibit the action of both desoxycorticosterone and aldosterone.[11]

Aldosterone is formed and secreted by the zona glomerulosa of the adrenal cortex, a process which goes on in the absence of ACTH.[6] The average man on a normal sodium intake will secrete between 40 and 180 micrograms of aldosterone during a twenty-four hour period. Because the half-life of the hormone is only 35 to 50 minutes, circulating levels are in the range of 0.01 micrograms per 100 ml. Aldosterone is metabolized by the liver and 90 per cent is excreted as the glucuronide of tetrahydroaldosterone. The remainder is excreted as conjugated 3-oxo-aldosterone and a tiny fraction as free aldosterone. It is the latter 10 per cent that is measured chemically; therefore, twenty-four hour urinary aldosterone levels are reported as ranging from 5 to 15 micrograms.

Renin-Angiotensin-Aldosterone System

Search for the regulatory mechanism of both aldosterone and renin drew these two substances together. Acute hemorrhage, which had been known to produce elevated renin levels, was found to be a most potent stimulus to aldosterone secretion. Similarly, constriction of the inferior vena cava, sodium depletion, constriction of the renal artery, and even the upright position in man were all shown to produce elevation of both renin and aldosterone levels.[2,12] The granularity of the juxtaglomerular cells (indicative of renin content) was shown to be increased in Addison's disease and decreased following injections of desoxycorticosterone.[8] Administration of renin, on the other hand, will produce hypertrophy of the zona glomerulosa of the adrenal gland and a graded response in aldosterone secretion in man.[13] Moreover, non-pressor levels of infused angiotensin II will cause increased secretion of aldosterone. The nephrectomized animal has low basal levels of aldosterone and will not respond to acute hemorrhage with increased aldosterone levels,[14] and the apparent sodium-retaining effect of angiotensin II is absent in the adrenalectomized animal.[14,17,18] All these observations led to the conclusion that angiotensin II is the aldosterone-stimulating hormone and that its regulation is dependent upon renin secretion. At present it is not possible to say whether renin secretion is regulated by blood volume, sodium concentration, or both.

At any rate, the system, as schematized in Figure 1, is thought to operate in the following manner. The juxtaglomerular apparatus of the afferent renal arteriole contains "stretch" receptors (or possibly a sodium-load chemoreceptor). The stimulus for renin release from the granules in these cells is a decrease in plasma volume (or sodium concentration) which causes a decrease in "stretch." The released renin then converts angiotensinogen to angiotensin I, which is subsequently converted to angiotensin II. Angiotensin II stimulates the zona glomerulosa of the adrenal cortex to secrete aldosterone. Aldosterone acts upon the distal renal tubule, the sweat glands, and the salivary glands to conserve sodium by enhancing the potassium sodium exchange mechanism. Water is reabsorbed along with the sodium, the plasma volume increases, "stretch" on the receptors then increases, and the stimulus for renin release is shut off.[19]

Fig. 1 — Renin-Angiotensin-Aldosterone System.

Physiologic Considerations

The observation of the above system as a physiologic mechanism was first noted by Conn in his study of the acclimatization of man to a warm climate. Large volumes of sodium-rich sweat are lost, and the individual becomes readily fatigued secondary to his sodium and water depletion. However, over a period of 10 to 20 days he is able to regain his sodium balance, even though he is still perspiring. This comes about through an elevation of the aldosterone level and a marked drop in the sodium content of the urine, sweat and saliva. Moreover, the plasma volume is

Continued

increased, and this is probably necessary for increased perfusion of the skin to occur. A very interesting, but as yet unexplained phenomenon occurs in these individuals, as well as in individuals given exogenous desoxycorticosterone or aldosterone.[10,20] This phenomenon, known as "renal escape," is that the effect of aldosterone on conservation of sodium becomes inoperable in the kidney while still operating on the sweat and salivary glands. It is indeed fortunate that this occurs, since the kidney can initially retain large amounts of sodium in the event of an acute shortage, but can then return to handling an excess of sodium when a new equilibrium has been established.

Similarly, persons fed a low sodium diet will show increased aldosterone levels. It was mentioned previously that the upright position caused an elevation of both renin and aldosterone levels; so the recumbent position causes a decrease in aldosterone and renin levels. The explanation for these postural differences is that the effective blood volume is increased in recumbency and decreased in the upright position.

Pathology

One can visualize from the above description of the system several ways in which the mechanism can be kept in operation. One would be a constant low plasma volume or sodium level, a second, a constant elevation of renin levels, and a third, constant elevation of aldosterone levels. It is on this basis that the syndromes of excessive aldosterone secretion will be dealt with. The first and second states will be considered as secondary aldosteronism, and the third state as primary aldosteronism (Table 1). Such a condition occurs in the edematous states of nephrosis, cardiac

Constant Low Plasma Volume or Sodium Level

The excess aldosterone secretion due to a constant low blood volume or low sodium concentration can be considered as a compensatory mechanism.

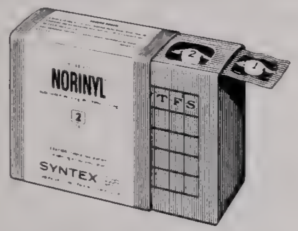
plus important supportive benefits that help her through those critical early months of oral contraception

low incidence of side effects

Low incidence of BTB and spotting, nausea and amenorrhea tends to minimize side effect problems and increases patient cooperation.

no confusion about dosage

An unbreakable "confusionproof" package makes it easy to adhere to prescribed dosage schedule: individually sealed tablets numbered from 1 through 20 *plus* monthly calendar record enables patient to double-check dosage intake by day and corresponding tablet number.



Contraindications: Thrombophlebitis or pulmonary embolism (current or past). Existing evidence does not support a causal relationship between use of Norinyl and development of thromboembolism. While a study which was conducted does not resolve definitively the possible etiologic relationship between progestational agents and intravascular clotting, it tends to confirm the findings of the Ad Hoc Advisory Committee appointed by the Food and Drug Administration to review this possibility. Cardiac, renal or hepatic dysfunction. Carcinoma of the breast or genital tract. Patients with a history of psychic depression should be carefully studied and the drug discontinued if depression recurs to marked degree. Patients with a history of cerebral vascular accident.

Warning: Discontinue medication pending examination if there is sudden partial or complete loss of vision, or if there is a sudden onset of proptosis, diplopia or migraine. If examination reveals papilledema or retinal vascular lesions, medication should be withdrawn.

Precautions: By May 1963, experience with norethindrone 2 mg.—mestranol 0.1 mg. had extended over 24 months. Through miscalculation, omission or error in taking the recommended dosage of Norinyl, pregnancy may result. If regular menses fail to appear and treatment schedule has not been adhered to, or if patient misses two menstrual periods, possibility of pregnancy should be resolved before resuming Norinyl. If pregnancy is established, Norinyl should be discontinued during period of gestation since virilization of the female fetus has been reported with oral use of progestational agents or estrogen. When lactation is desired, withhold Norinyl until nursing needs are established. Existing uterine fibroids may increase in size. In metabolic or endocrine disorders, careful clinical preevaluation is indicated. A few patients without evidence of hyperthyroidism had elevated serum protein-bound iodine levels, which in the light of present knowledge, does not necessarily imply hyperthyroidism. Protein-bound iodine increased following estrogen administration. Bromsulphalein retention has occurred in up to 25% of patients without evidence of hepatic dysfunction. Studies from 24-hour urine collections have shown an increase in aldosterone and 17-ketosteroids and decrease in 17-hydroxycorticoid levels. Thus, Norinyl should be discontinued prior to and during thyroid, liver or adrenal function tests. Because progestational agents may cause fluid retention, conditions such as epilepsy, migraine and asthma require careful observation. Thus far no deleterious effect on pituitary, ovarian or adrenal function has been noted; however, long-range possible effect on these and other organs must await more prolonged observation. Norinyl should be used with caution in patients with bone, renal or any disease involving calcium or phosphorus metabolism.

Side Effects: Intermenstrual bleeding; amenorrhea; symptoms resembling early pregnancy, such as nausea, breast engorgement or enlargement, chloasma and minor degree of fluid retention (if these should occur and patient has not strictly adhered to medication plan, she should be tested for pregnancy); weight gain; subjective complaints such as headache, dizziness, nervousness, irritability; in a few patients libido was increased. In a total of 3,090 patients, 2.2% discontinued medication because of nausea.

NOTE: See sections on contraindications and precautions for possible side effects on other organ systems.

Dosage and Administration: One Norinyl tablet orally for 20 days, commencing on day 5 through and including day 24 of the menstrual cycle. (Day 1 is the first day of menstrual bleeding.)

Availability: Dispensers of 20 and 60 tablets; bottles of 100.

for multiple contraceptive action

failure, cirrhosis and idiopathic edema. Although the major problem in these conditions is sodium and water retention, the actual intravascular volume is low and therefore acts as a stimulus for renin release and aldosterone secretion. An additional factor in right heart failure, and especially in cirrhosis, is a decreased rate of metabolism of aldosterone by the liver, whereby further elevation of aldosterone levels occurs. Hence the body is stimulated to conserve more sodium and more water, which escapes into the extravascular space, and a "vicious circle" ensues. Probably the reason that hypertonic saline sometimes produces a diuresis in these patients is that aldosterone production is shut off by this maneuver.

Salt restriction, salt-losing nephritis, diabetes insipidus, and salt-depleting diuretics will all produce an elevation of aldosterone.

Elevation of Renin

The condition of overproduction of renin will be considered as primarily pathologic. This occurs in renal hypertension, whether on the basis of renal artery stenosis or renal arteriolar constriction. Actually, this could be considered a localized decrease in blood volume to the juxtaglomerular apparatus.[2] Renin levels are elevated in Addison's disease, if untreated with mineralocorticoids, but do not produce hypertension under these circumstances. The elevated renin levels of renal hypertension do produce secondary aldosteronism, however, and it is this category of patients that presents the greatest problem in the differential diagnosis of primary aldosteronism.

Elevation of Aldosterone

Primary aldosteronism is caused by the autogenous secretion of aldosterone from an adrenal cortical adenoma. Because of this the blood volume should be expanded, the serum sodium level normal or increased, and the stimulus for renin release absent; therefore renin levels should be low.

Recognition of the syndrome of mineralo-corticoid excess in its flagrant form with hypertension, hypernatremia, hypokalemic alkalosis, increased urinary potassium, and the clinical symptoms of headache, malaise, polyuria, polydipsia, and muscle weakness should not be difficult and can readily be confirmed by an elevated urinary aldosterone level.[21] This does not, however, differentiate primary from secondary aldosteronism of renal origin. It has been proposed that an evaluation of the plasma volume will make this differentiation, but the overlap of results in these two syndromes is enough to warrant a better method.[22,23]

Conn, using the reasoning given above, suggested that the real differentiation between these two syndromes could be made on the basis of renin level determinations. Even though others had reported renin levels of patients with primary aldosteronism to be normal,[24] Conn pointed out that the most reliable test for renin levels that were low on the basis of suppression by an autogenous tumor would be to do the assay under conditions of maximal stimulation for renin secretion. By keeping patients on a sodium intake of 10 milliequivalents per day for several days, and then obtaining a blood sample after they had been in an upright position for at least four hours, Conn was able to separate clearly the normals from the patients with primary aldosteronism.[2]

Having proved the usefulness of the observation of increased aldosterone levels accompanied by decreased renin levels in the diagnosis of primary aldosteronism, Conn then suggested that hypertensive individuals with aldosterone-secreting tumors must go through the stages of the acclimatized man. In other words, hypertensives, on a good potassium intake and manifesting the "renal escape" phenomenon, must not only exist, but were probably labeled as essential hypertensives, were put on a low sodium diet, and had their aldosterone-secreting adenomas masked for years.[4] In 1965 he reported just such a case.[3]

Theoretical Considerations

Because the adenomas removed from patients with primary aldosteronism are indistinguishable from the benign adrenal cortical adenoma found at autopsy, and because he had proven to his own satisfaction that normokalemic primary aldosteronism exists as a curable cause of hypertension, Conn has suggested that 20 to 25 per cent of persons with so-called essential hypertension actually have aldosterone-secreting adenomas of the adrenal cortex. His reasoning is based on the review of several autopsy studies. In 1945 Russi reported a series of 9,000 autopsy cases in which the incidence of adrenal cortical adenoma was 3.7 per cent. The incidence of hypertension in this series was 14 per cent; but 73 per cent of the adenomas were in the hypertensive group. In other words, 19 per cent of the hypertensives had adrenal cortical adenomas.[5] Then, comparing a matched group of 220 hypertensives with 220 non-hypertensives, 1.8 per cent of the non-hypertensives and 20 per cent of the hypertensives had adrenal cortical adenomas at autopsy. Similarly, in a group of 97 hypertensives

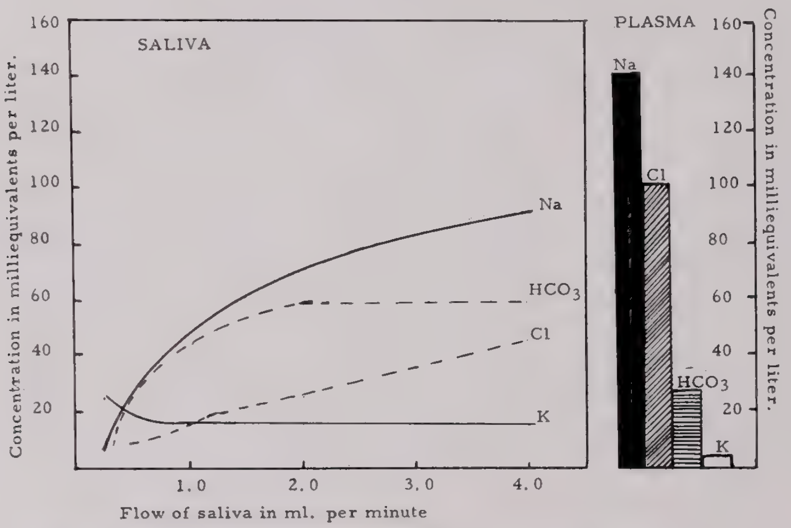
who had bilateral adrenalectomy for their disease, the incidence of adrenal cortical adenomas was 21 per cent.[4]

Reviewing Brown's renin assays in hypertensive subjects, Conn points out that in a group of 48 patients, 21 per cent had low renin levels. In another group of 13 hypertensives with low potassium levels, seven had definitely low renin levels and six had low normal levels, which Conn says could have been diagnostic if collected under the proper conditions.[4]



Saliva Na/K ratios	
Normal 0.61 to 3.37. Mean 1.47	Under 0.25 is diagnostic of aldosteronism. Under 1.0 is suspicious of aldosteronism. Thorn, G.: New Engl J Med 267: 1136, 1962.

Diagnostic Criteria

To simply suggest that all hypertensives should be screened with a renin assay is, at this time, totally impractical. While collection and preparation of the sample is no problem (Table 2), the actual assay is much more difficult.[25] The response of a nephrectomized, standardized rat to the infusion of the preparation shows how measurement of plasma renin levels are obtained.[2,25] A simpler method may be available in the future.

Table 3 summarizes a suggested approach to the patient who has hypertension of undetermined cause. Certainly the patient with hypokalemic alkalosis (even if he develops this while on thiazide diuretics) is a prime suspect. Although plasma volume determination has been suggested as a screening procedure, the determination of salivary sodium and potassium content seems to show more promise.[26,27] Figure 2 gives normal values for salivary electrolytes.

It is therefore suggested that while on a diet of 200 to 300 milliequiva-

lents of sodium daily, the subject rinse his mouth with 0.5 M citric acid to produce maximum salivary flow. On an adequate volume of saliva, the determination of Na. and K. can be made, and the Na./K. ratio determined. If it is below 1, a 24-hour urine collection is made for aldosterone determination. The subject is then placed on a diet of 10 milliequivalents of sodium daily for at least four days; then, following his being in the upright position for at least four hours, a blood sample is drawn and prepared for renin assay.

The diagnosis of primary aldosteronism can be made if the renin level is low and the aldosterone level is elevated. In the event that both renin and aldosterone levels are elevated, a search for renal causes of hypertension is in order. Table 1 summarizes the clinical conditions in which various combinations of these two substances are present.

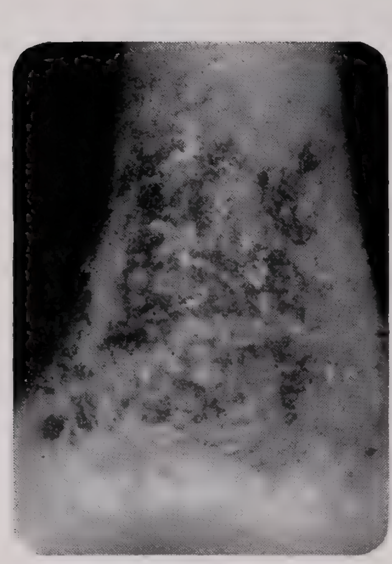
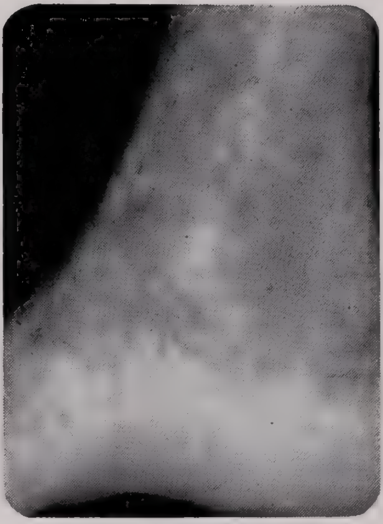
Who, then, is the invincible man? He whom nothing that is outside the sphere of his moral purpose can dismay. — Epictetus

Eczema of many years... controlled in two weeks



Before treatment



After treatment—
with ARISTOCORT Topical
Ointment 0.1% for two weeks

ARISTOCORT® Triamcinolone Acetonide Topicals have proved exceptionally effective in the control of various forms of eczema: allergic, atopic, nummular, psoriatic, and mycotic.

In most cases responsive to topical ARISTOCORT, the 0.1% concentration is sufficiently potent. The 0.5% concentration provides enhanced topical activity for patients requiring additional potency for proper relief.

Administration and Dosage: Apply sparingly to the affected area 3 or 4 times daily. Some cases of psoriasis may be more effectively treated if the 0.1% Cream or Ointment is applied under an occlusive dressing.

Contraindications: Tuberculosis of the skin, herpes simplex, chicken pox and vaccinia.

Precautions and Side Effects: Do not use in the eyes or in the ear (if drum is perforated). A few individuals react unfavorably under certain conditions. If side effects are encountered, the drug should be discontinued and appropriate measures taken. Use on infected areas should be attended with caution and observation, bearing in mind the potential spreading of infection and the advisability of discontinuing therapy and/or initiating antibacterial measures. Generalized dermatological conditions may require systemic corticosteroid therapy. Steroid therapy, although responsible for remissions of dermatoses, especially of allergic origin cannot be expected to prevent recurrence. The use over extensive body areas, with or without occlusive nonpermeable dressings, may result in systemic absorption. Appropriate precautions should be taken. When occlusive nonpermeable dressings are used, miliaria, folliculitis and pyodermas will sometimes develop. Localized atrophy and striae have been reported with the use of steroids by the occlusive technique. When occlusive nonpermeable dressings are used, the physician should be aware of the hazards of suffocation and flammability. The safety of use on pregnant patients has not been firmly established. Thus, do not use in large amounts or for long periods of time on pregnant patients.

Available in 5 Gm. and 15 Gm. tubes and ½ lb. jars.

Book Reviews

Man builds no structure which outlives a book. — E. F. Ware

RADIOLOGIC DIAGNOSIS IN INFANTS AND CHILDREN — Armond E. Brodeur: C. V. Mosby Co., St. Louis, 1965; 503 pages, Price $26.50.

This is a well-illustrated, concise book on pediatric radiology, based on the considerable personal experience of the author.

After an opening chapter, entitled "The Technique of Differential Diagnosis," the book is divided into five sections: Head and Neck, Thorax, Abdomen, Skeleton and Integument, and The Mistreated Child. Each of the first four sections consists of two to seven chapters under headings of the various organ systems. Each chapter or its subdivision begins with a description of the normal anatomy. The congenital and acquired abnormalities are then discussed. Finally, the pitfalls in diagnosis are pointed out. The author's presentation is pertinent and lucid. Of special value is the material on the mandible and the teeth, contributed by Richard J. Parmley.

The references, comprehensive and up to date, appear at the end of the volume. One might wish that they were listed under subject headings rather than authors.

The accomplished pediatric radiologist will find Dr. Brodeur's approach lacking in depth, if not in sophistication. The general radiologist and the pediatrician may discover sins of omission or dogmatism, but will pick up some pearls along the way. For the junior resident in radiology or pediatrics the book will provide a working knowledge and a quick survey of the field before he delves into a larger, standard work. It is primarily for this group and also for pathologists, interns, and medical students that this book is intended. To them it may be recommended.

CARDIAC EVALUATION IN NORMAL INFANTS — R. F. Ziegler, C. V. Mosby Co., St. Louis, 1965.

This small book is concerned with the problems of evaluating the cardiovascular system in the neonatal period. The transition of the circulatory system from the fetal to the adult type pattern must be considered in this evaluation, since it can result in clinical and laboratory findings which may be normal in this age period, but are distinctly abnormal later in life.

The first three chapters are concerned with the definition of normal, the fetal circulation, and changes in the circulation occurring at birth. On this base, the next four chapters are formulated. These deal with evaluation of cyanosis, cardiac murmurs, cardiac rate and rhythm, and the heart size, all of which are problems on which the pediatrician is frequently consulted. In the discussion of these signs or symptoms the various factors causing them and ways to approach them in evaluation are presented. The final two chapters are concerned with more specific problems such as the heart in respiratory distress syndrome and evaluation of growth retardation.

The author's major interest within the field of pediatric cardiology is electrocardiography, and this laboratory tool is emphasized throughout the book and its applications to clinical problems is stressed.

The bibliography is comprehensive. Two deficiencies are noted in the book. The first is that reproduction of the electrocardiogram is poor. The second is that in portions of the book the reading is difficult because of sentence construction. Despite these drawbacks, this book should be useful to pediatricians and to pediatric cardiologists.

SURGERY OF THE FOOT — Second Edition, Henri L. DuVries, C. V. Mosby Company, 1965, $17.50.

This is an excellent book for all general practitioners who must cope with the multitude of foot problems occurring in everyday practice. Common and troublesome lesions like warts and calluses are not ignored but treated with a thoroughness that reflects the author's extensive personal experience. It is nicely illustrated.

It should be valuable reading for the general surgeon and orthopedic surgeon also. The senior author has, for instance, treated on a referral basis over 150 patients who had had a Keller type hallux valgus procedure that failed to provide a satisfactory result. His words of caution are worthy of attention.

The book is quite detailed and a good reference for office use.

pyelonephritis?
pyelitis?
urethritis?
prostatitis?

in any case,
usually gram-negative*

Therapy:

two 500 mg. Caplets® q.i.d
(initial adult dose)

NegGram

Brand of
nalidixic aci

a specific anti-gram-negative

eradicates most urinary tract infections...

- Low incidence of untoward effects; no fungal overgrowth, crystalluria, ototoxic or nephrotoxic effects have been observed.
- "Excellent" or "good" response reported *in more than 2 out of 3* patients with either chronic or acute gram-negative infections.[1]

Indications: Urinary tract infections caused by gram-negative and some gram-positive organisms.

Side effects: Mainly mild, transient gastrointestinal disturbances; in occasional instances, drowsiness, fatigue, pruritus, rash, urticaria, mild eosinophilia, reversible subjective visual disturbances (overbrightness of lights, change in visual color perception, difficulty in focusing, decrease in visual acuity and double vision), and reversible photosensitivity reactions. Marked overdosage, coupled with certain predisposing factors, has produced brief convulsions in a few patients.

Precautions: As with all new drugs, blood and liver function tests are advisable during prolonged treatment. **Pending further experience, like most chemotherapeutic agents, this drug should not be given in the first trimester of pregnancy. It must be used cautiously in patients with liver disease or severe impairment of kidney function.** Because photosensitivity reactions have occurred in a small number of cases, patients should be cautioned to avoid unnecessary exposure to direct sunlight while receiving NegGram, and if a reaction occurs, therapy should be discontinued. The dosage recommended for adults and children should not arbitrarily be doubled unless under the careful supervision of a physician. Bacterial resistance may develop.

When testing the urine for glucose in patients receiving NegGram, Clinistix® Reagent Strips or Tes-Tape® should be used since other reagents give a false-positive reaction.

Dosage: Adults: Four Gm. daily by mouth (2 Caplets® of 500 mg. four times daily) for one to two weeks. Thereafter, if prolonged treatment is indicated, the dosage may be reduced to two Gm. daily. Children may be given approximately *25 mg. per pound* of body weight per day, administered in divided doses. The dosage recommended above for adults and children should not arbitrarily be doubled unless under the careful supervision of a physician. Until further experience is gained, infants under 1 month should not be treated with the drug.

How supplied: Buff-colored, scored Caplets® of **500 mg. for adults,** conveniently available in bottles of 56 (sufficient for one full week of therapy) and in bottles of 1000. **250 mg. for children,** available in bottles of 56 and 1000.

*As many as 9 out of 10 urinary tract infections are now caused by gram-negative organisms: E. coli, Klebsiella, Aerobacter, Proteus, Paracolon or Pseudomonas[2]... However, infections of the urethra and prostate caused by non-gonococcal gram-negative organisms are believed to be less prevalent.

Advances

Antibacterial Management of Infections Due to Gram-Negative Bacilli

Part IV. Principles of Management, Empiric Therapy, and Some Infections of the Respiratory Tract*

WILLIAM J. MARTIN, M.D.**
Rochester, Minneota

HAVING COMPLETED the presentation of the antibacterial agents pertinent to the management of infections due to gram-negative bacilli, we are now in an improved position to discuss some of the various diseases caused by these bacteria and to indicate more specifically which drugs are employed. However, prior to tabulating these diseases, it may be wise to present certain principles of management, as well as the generalities of empiric therapy; this therapy often is required in life-threatening infections when the clinical status of the patient makes initiation of treatment necessary prior to the report of microbiologic data. Such empiric therapy is necessary, for example, when a gram-stained specimen of spinal fluid, especially that from a child, reveals the presence of gram-negative bacilli. Also, therapy may be mandatory when cultures are described as growing a pathogen, yet in-vitro bacterial susceptibility tests may not be reportable for another one or two days. In addition, it is not rare in patients in whom bacteremia due to gram-negative bacilli is strongly suspected clinically, for therapy to be initiated empirically after blood is drawn for cultures. Therefore initial therapy cannot routinely be based on the results of cultures and in-vitro susceptibility tests and consequently is often empiric.

Principles of Management

The principles of management of patients having serious infection due to gram-negative bacilli can be summarized as follows: (1) procurement of samples for adequate microbiologic study and initiation of empiric treatment thereafter if the condition of the patient warrants; (2) reevaluation if results of cultures and in-vitro bacterial susceptibilities later indicate a poor choice of antibacterial therapy, but continuation of the empiric regimen if the patient is doing well; (3) procurement of serum bactericidal tests in selected infections to help determine if the bacteria are eradicable by the regimen employed; (4) administration of the drug or drugs in adequate dosage for a sufficient time; and (5) correction of any condition predisposing to the infection or complicating it.

Empiric Therapy

For the most part, in-vitro susceptibility of the organisms to various antibiotics has only retrospective value in the management of serious infection due to gram-negative bacilli because, as aforementioned, therapy often is initiated empirically before such findings are available and ordinarily is not changed if the patient is doing well. To postpone therapy until the results of in-vitro sus-

Continued

The six parts of this paper were presented, in part, at the Symposium on Antibacterial Agents sponsored by the Southern California Society of Hospital Pharmacists, Los Angeles, California, May 2, 1965.

*See Part III, Minnesota Med 49:1161, 1966.

**Mayo Clinic and Mayo Foundation: Section of Medicine.

ceptibility tests are available would mean a delay of 24 to 48 hours and an increased chance of mortality.

There is no dispute regarding the generalization that best results are obtained when the infecting organisms are sensitive on in-vitro tests to the antimicrobial agents employed; the difficulty lies in the unavailability of such data when the clinical status of the patient makes initiation of therapy necessary.

Recently, combined antibiotic therapy with a tetracycline and streptomycin or chloramphenicol and kanamycin has been the regimen employed most frequently by members of our group in the empiric management of serious infection due to gram-negative bacilli. Such a regimen, begun before results of in-vitro susceptibility tests were reported, in cases in which gram-negative bacillary infection was present or likely, provided broader antibacterial coverage than a single agent. Also, infection due to *Klebsiella-Aerobacter* and *Proteus* organisms appears to exemplify a therapeutic paradox since in some of our cases, in-vitro studies indicated resistance to the tetracyclines and streptomycin; yet combined treatment with these antibiotics was followed by recovery. The exact basis for this remains obscure. The phenomenon does not appear equally applicable to certain other infections such as those due to *Escherichia coli.*

Of our patients with serious infection due to gram-negative bacilli, in whom such empiric therapy has been employed during the last few years, approximately 70% have received both streptomycin and a tetracycline drug, and most of the remaining patients have received chloramphenicol and kanamycin. As empiric therapy, my colleagues and I have preferred tetracycline to chloramphenicol because the latter may depress the marrow, and we have preferred streptomycin to kanamycin, since kanamycin is more likely to cause deafness.

With the advent of newer drugs, we have reevaluated this policy. Colistin, like polymyxin B, has the disadvantage that *Proteus* organisms are usually resistant. Kanamycin, if used alone, has the therapeutic inadequacy of not being effective against many *Pseudomonas* organisms and most *Bacteroides* organisms.

Ampicillin is inactive against *Proteus* organisms that are indole-positive as well as *Klebsiella-Aerobacter* and *Pseudomonas* organisms. Cephalothin is not active against all *Klebsiella-Aerobacter* organisms and indole-positive *Proteus* organisms and usually is inactive against *Pseudomonas* and *Bacteroides* organisms. To date, there is no single agent available that assures complete "coverage" against gram-negative bacillary infections.

A regimen more acceptable than a tetracycline and streptomycin combination would be welcome because of the latter's disadvantages, which include the dual depressive effect on the gram-negative elements of the flora and the increased likelihood of coccal superinfection and of streptomycin's ototoxicity. However, there are also disadvantages with alternative antibacterial regimens. As aforementioned, kanamycin is ototoxic and chloramphenicol is hematotoxic; and when they are used conjointly there is also a dual depressive effect on the gram-negative flora. Polymyxin B and colistin can be neurotoxic, perhaps nephrotoxic, and can induce coccal superinfection. Ampicillin can cause anaphylaxis and the other untoward reactions characteristic of the penicillins and induces superinfection in about 5% of patients. Cephalothin has caused transient neutropenia, perhaps is nephrotoxic, and may induce superinfection from *Pseudomonas* and *Bacteroides* organisms. When the patient's clinical course is satisfactory, usually the empiric regimen is continued despite in-vitro susceptibility tests indicating bacterial resistance.

When the patient is not doing well clinically, the empiric regimen is replaced with the following agents in keeping with the results of the susceptibility tests. Ampicillin, cephalothin, kanamycin, polymyxin B, or colistin may be useful in infections due to *E. coli*; except for ampicillin, the same drugs are considered against *Klebsiella-Aerobacter* organisms. Ampicillin and cephalothin are effective against *P. mirabilis*. Cephalothin and kanamycin may be useful against indole-positive *Proteus* organisms. Polymyxin B or colistin are the drugs of choice against *Pseudomonas*. Ampicillin, cephalothin, and kanamycin may be applicable to *Salmonella* infections.

With these principles of management in mind and the consideration of the frequent need that initial therapy be empiric, the antibacterial management of some of the diseases caused by gram-negative bacilli can be discussed.

Some Infections of the Respiratory Tract

Infections of the upper respiratory tract such as acute pharyngitis, otitis media, mastoiditis, and sinusitis may be caused by *Haemophilus influenzae,* especially in children, but beta-hemolytic streptococci, staphylococci, and pneumonococci more commonly are responsible. In cases of influenzal cause, a tetracycline, ampicillin, or a sulfonamide may be used. Erythromycin occasionally is useful. Because of its hematotoxicity, use of chloramphenicol is avoided.

Obstructive Laryngitis

In children acute obstructive laryngitis with epiglottitis is commonly due to *H. influenzae,* and immediate use of tetracycline-streptomycin, ampicillin or chloramphenicol is indicated. Tracheostomy may be necessary.

Vincent's Angina

Vincent's angina, wherein infection due to fusospirochetal organisms results in multiple ulcers covered with a gray, necrotic pseudomembrane involving the tonsils and pharynx, is best treated with penicillin. However, the tetracyclines also are effective and have use in patients allergic to penicillin.

The Thyroid Gland

Considerable confusion with infections of the upper respiratory tract can be caused by infection of the thyroid gland. Bacterial infection of the thyroid is rare but may progress to abscess formation. Thyroid infection is said to be commoner in goitrous and cystic glands, and in association with a persistent thyroglossal duct. However, normal thyroids can be infected as a complication of bacteremia, cellulitis of the neck, or an infection of the upper respiratory tract. Various cocci or tubercle bacilli may be causative; rarely Enterobacteriaceae including *S. typhosa* have been responsible. A semisynthetic antistaphylococcal penicillin given conjointly with a tetracycline or chloramphenicol would provide initial antibacterial coverage; perhaps ampicillin or cephalothin should be considered. Surgical drainage provides a more specific microbiologic diagnosis and helps prevent spread of infection to the mediastinum.[1]

Pneumonia

Pneumonia caused by *H. influenzae* may be primary in a child but usually is secondary to viral disease in an adult. Tetracycline-streptomycin or chloramphenicol has been the regimen used most often in influenzal pneumonia, but ampicillin and cephalothin probably will have future use.

Pneumonia due to *Klebsiella pneumoniae* is more common in alcoholics, diabetics, and patients with cirrhosis; nearly 50% of such patients have bacteremia. *Klebsiella* organisms have an affinity for the upper part of the lungs, and the reaction often is lobar. Tetracycline or chloramphenicol plus streptomycin has been used most often.

Of the pneumonias due to *Pasteurella* organisms, there is the pulmonic form of plague caused by *P. pestis* and requiring streptomycin-tetracycline therapy. In tularemia caused by *P. tularensis,* streptomycin or a tetracycline may suffice, but in infections due to *P. multocida,* penicillin is preferred. In regard to human plague, the World Health Organization noted the occurrence of 1,457 cases with 121 deaths in 1964; corresponding figures for 1963 were 862 cases and 142 deaths. In South Vietnam there were 300 cases in 1964, as against 115 in 1963. Major areas of human plague in the Americas in recent years have included Ecuador, Peru, Brazil, and Bolivia.

In pneumonia from *Salmonella* organisms, a tetracycline, chloramphenicol, kanamycin, ampicillin, or cephalothin is used, depending on the bacterial species.

Continued

Pneumonia due to other Enterobacteriaceae as well as to *Pseudomonas* and *Bacteroides* organisms is a hazard of penicillin and allied therapy because of antibiotic-induced floral changes. Gram-negative bacillary pneumonia, especially that caused by *Pseudomonas* and other "water bacilli," also occurs after use of contaminated inhalational equipment, resuscitation equipment, tracheal catheters, and tracheostomy procedures, which may deposit inocula of these organisms in the pulmonary tree. In pneumonia due to Enterobacteriaceae, tetracycline-streptomycin and chloramphenicolkanamycin have each been successful; ampicillin or cephalothin is considered in resistant cases. In pneumonia due to *Pseudomonas*, polymyxin B or colistin is used. *Bacteroides* pneumonia is treated with a tetracycline.

Empyema

Empyema due to gram-negative bacilli complicates such situations as pneumonia, chest wall trauma, esophageal disease, and surgery or occurs on perforation or extension of subdiaphragmatic infections. Enterobacteriaceae and *Bacteroides* organisms usually are present in the latter processes. Empyema due to type b *H. influenzae* may be of increasing incidence in children. Systemic antibacterial therapy as previously outlined for pneumonia due to these organisms is given, but the regimen may be altered to include drugs effective against enterococci and staphylococci when the lesion results from a subdiaphragmatic infection. In certain cases, intermittent pleural aspiration and instillation of antibiotics may be carried out. The empyema cavity is aspirated as completely as possible, and the antibiotic is injected in 10 to 20 ml. of saline solution before the needle is removed. The fluid is aspirated daily and, if it is viscous, the cavity is irrigated with 100 or 200 ml. of saline solution before the antibiotic is instilled. If the fluid becomes loculated, enzymatic debridement with either crystallin, trypsin or a combination of streptokinase and streptodornase is considered. The enzymes are injected every two to three days for two to three weeks. Definitive therapy of the lesion may necessitate surgical intervention, especially when it reflects subdiaphragmatic infection.

Abscess

Lung abscess is usually due to coccal organisms, but among the potentially causative gram-negative bacilli are the fusospirochetal organisms, with which infection may result in gangrene. Abscess due to these organisms occurs more frequently in the right lung, ostensibly because the right main bronchus is, except for a slight deviation toward the right, a continuation of the trachea which favors aspiration of contaminated secretion from the oral cavity. Penicillin is the antibiotic of choice. Surgery is necessary in more than 50% of cases.

Chronic Bronchitis

In chronic bronchitis or bronchiectasis characterized by repeated episodes of acute infection or pneumonitis, there is difficulty in identifying the responsible pathogen even when smears and cultures are made of material obtained by bronchial aspiration. In addition to various cocci, *H. influenzae, P. multocida,* and fusospirochetal organisms may be isolated. When such gram-negative bacilli are isolated consistently, use of a drug such as ampicillin is considered. Long-term suppressive antimicrobial therapy to prevent exacerbations has not been consistently successful. Surgery remains the only method of cure in bronchiectasis. Hypogammaglobulinemia, especially of the acquired type, may be characterized by repeated pulmonary infections, including those due to *H. influenzae* which may eventuate in chronic bronchitis or bronchiectasis and for which administration of gamma globulin may be helpful.

Cystic Fibrosis

In cystic fibrosis the prognosis may depend largely on the course of the respiratory involvement. Pathogens isolated from the respiratory tract in victims of this syndrome include various cocci and *H. influenzae* and *Pseudomonas* organisms. Frequent microbiologic monitoring of the respiratory tract and use of specific drugs accordingly may be preferable to attempts at antimicrobial prophylaxis.

Pertussis

Despite in-vitro susceptibility of *Bordetella pertussis* to various drugs including the tetracyclines and chloramphenicol, antibiotic treatment of uncomplicated whooping cough has been disappointing. A tetracycline or chloramphenicol may reduce the severity of the disease, but only if given in the first week of the illness. The typical cough usually does not appear within the first week of the onset, so that by the time the diagnosis is made, antibiotics are of little avail. Bronchopneumonia results from secondary infection usually caused by pneumococci, streptococci, and organisms of *H. influenzae.* In complicating bronchopneumonia due to *H. influenzae,* either streptomycin-tetracycline or chloramphenicol may be effective, but ampicillin and cephalothin warrant consideration.

Minnesota State Board of Medical Examiners

The Minnesota State Board of Medical Examiners and the State Examining Committee for Physical Therapists have announced that persons desiring to take the examination for registration of physical therapists must be graduates of a school of physical therapy approved by the Board for training physical therapists, in addition to the other statutory qualifications. Persons interested in determining their eligibility to take the examination for registration in physical therapy are advised to contact the Board in order to insure that the school they propose to attend is one approved by the Board.

Grand Rounds

In the fall of 1923 Dr. Bela Schick assumed the Directorship of the Pediatric Department at The Mount Sinai Hospital, New York. From the beginning he held his grand rounds and later his conferences on Thursdays. He started promptly at 9:30 A.M. no matter how small the gathering was. One morning during the depression years in the thirties there was an overflow attendance. Schick was delighted and commented, "There must be an epidemic of health."

The following week when the attendance fell off, Schick remarked, "Practice apparently is already better." — I. J. Wolf, M.D.: Aphorisms and Facetiae of Bela Schick.

POSTEROLATERAL APPROACH
A BACK DOOR TO INFECTED TIBIAL SHAFT FRACTURES

Nonunion of tibial fractures complicated by a discharging fistula over the subcutaneous surface of the bone calls for special therapeutic measures. The present paper reports on a method given little attention and seldom used, but which was employed successfully in four cases. The fractures had been variously treated, including bone grafts through incisions on the anterior surface of the bone, with nonunion still present several months to more than two years later. In two instances the procedure was the only alternative to amputation.

A posterolateral approach to the tibia permits exposure away from the sinus and from infected unhealthy tissue. The implantation of osteogenic material entails the least possible danger of sequestration when purely cancellous bone is introduced behind the interosseous membrane with only external fixation. The principle is to produce a strong bridging of bone plate behind the interosseous membrane, uniting the tibia and fibula both above and below the site of nonunion.
Operative Technique:

The material used is a large amount of chipped bone from the crest and cancellous posterior part of the iliac bone. The incision in the leg is along the posterolateral surface of the fibula. Dissection is posterior to the interosseous membrane separating the muscles, vessels, and nerves well above and below the fracture line. The tissues are separated subperiosteally from the tibia. The dorsal surfaces of the tibia and fibula are chipped with a chisel. The cancellous bone in an unbroken mass is introduced over this denuded area of bone and interosseous membrane. Hemostasis is secured by compression and the wound is closed loosely. A posterior plaster cast is applied.

Case Reports

Case 1.

A male, 28 years old, was admitted two years after an accident, with nonunion and a discharging fistula. Through the posterolateral approach bone grafting was performed. Support was used for four and a half months. The patient returned to work in six months.

Continued

Case 2.

This patient had a similar history and operation for nonunion and fistula of the tibia two years after injury. After plaster immobilization for three and one-half months he returned to work in six months.

Case 3.

This patient with a similar history of seven months duration was operated upon. Union with bridging bone permitted return to work in four months after surgery.

Case 4.

A female, 33 years of age, sustained a complicated, contaminated comminuted tibial fracture. Eighteen months later she had nonunion and an infected sinus. Similar surgery was instituted. Union of the bones was slow, and 12 months passed before weight-bearing was permitted. The precautionary measure of using a cane for two and one-half years was advisable.

Summary

Bone grafting by the posterolateral approach was successful in four patients with nonunion and infection. This approach permits surgery through a sterile field. Two patients in whom amputation had been contemplated were rehabilitated.

SYNOVECTOMY FOR RHEUMATOID ARTHRITIS

The author has used synovectomy of the knee on 50 occasions on patients ranging from 11 to 78 years of age. All of these patients suffered disabling pain with or without instability whenever there was swelling of the synovium. Doctor Narmor and his associates did not consider that the usual x-ray changes associated with rheumatoid arthritis were a contraindication for synovectomy, and they thought that early flexion deformities could be corrected if the patient was relieved of the pain which caused the flexion deformity.

In the technique they removed the thickened synovium from all of the joint surface but did not remove the synovium from the suprapatellar bursa. When the meniscus was found to be invaded by the inflammatory process, it too was removed.

The approach to the knee joint was through a medial and a lateral incision. They reported that the majority of patients were restored to function with not less than a 70-degree arc of motion within a week. They consider that the removal of the synovium relieves the patient's pain and prevents or delays the progress of the disease progress, and they believe that early activity after the operation is of importance.

MEASLES AND MULTIPLE SCLEROSIS

Although the etiology of measles encephalitis is not clear, its pathological process is characterized by diffuse disseminated demyelinating lesions. Since a demyelinating process is considered characteristic of multiple sclerosis (MS), the authors investigated the measles antibody titers in the serum of over 100 patients with MS. Spinal fluid titers were similarly investigated in 35 MS patients. The examination of the sera of MS patients by neutralization and complement fixation tests revealed slightly higher antibody titers than did those of healthy control subjects. The cerebrospinal fluid of patients with MS showed measurable antibody titers to measles virus in over 75% of cases tested, whereas control subjects showed no evidence of antibodies. These observations on measles antibodies in the serum and spinal fluid of patients with MS do not imply or indicate a direct relationship, but warrant continuing investigation.

A COMPARISON OF HALOPERIDOL AND TRIFLUOPERAZINE: A DOUBLE-BLIND, CONTROLLED STUDY ON CHRONIC SCHIZOPHRENIC OUTPATIENTS*

Haloperidol, an investigational butyrophenone, was compared with trifluoperazine, a well-established and effective antipsychotic agent, in a population of chronic schizophrenic outpatients, using a double-blind technique. After a two-week washout period, 26 patients started the study, with 13 taking each drug. Nine patients completed a three-month trial, five of whom were taking haloperidol. Only two haloperidol patients were sufficiently improved to warrant their continued treatment with this medication; but statistical analysis of the Brief Psychiatric Rating Scale total scores and individual subscores for each drug group after the first month of the trial demonstrated a statistically significant superiority for haloperidol on three subscales. There was a relatively higher incidence of extrapyramidal reactions associated with the study drug. The development of weakness, drowsiness, and depression necessitated withdrawing haloperidol from three patients who completed the study. The dosage ratio utilized may have placed the drug at a disadvantage. However, it may be of value in controlling chronic paranoid patients refractory to other major tranquilizers. The size of the sample in this trial prohibits a more definite statement about the effect of haloperidol on any specific symptom.

THE USE OF AIDES IN PHYSICAL MEDICINE

At a meeting on March 17, 1966, the Minnesota Physiatric Society adopted the position with regard to the use of aides in physical medicine and rehabilitation that such persons be employed only in positions where they are under the close, constant, personal supervision of the qualified person whom they are aiding.

Continued

We urge that this principal be recognized and maintained by the medical and hospital community in Minnesota.

G. Keith Stillwell, M.D.
President
Minnesota Physiatric Society

AUTOMATED SCREENING FOR DISEASE

Two years ago physicians and chemists at Duke University Medical Center started a survey to find out if routine automated screening of blood chemistries uncovered enough disease to justify the expense. They compared the data obtained from blood submitted to the routine laboratory to that done automatically by a multichannel analyser. For their automated tests, they chose glucose, urea, sodium, potassium, chloride, carbon dioxide content, calcium, phosphorous, total protein, albumin, and uric acid. For their patients, they used adults admitted to a university, a community, and a veteran's hospital. They performed the tests on 2846 consecutive patients and showed abnormalities in 850 or 30% of them. In 42% of the 850 patients, automated analysis yielded abnormal tests not ordered by the patient's physician. In about one of every 12 patients, the physicians caring for them considered the unexpected data to be medically significant. The cost of automated analysis of 11 tests on each patient was roughly equal to the usual cost of two standard blood chemistries. The authors conclude that a "profile of admission chemical data" is worthwhile. Because of enthusiastic acceptance by physicians, the tests have been done routinely since early 1965 on all adult patients.

COLON POLYPS

Incidence and distribution of adenomatous polyps of the large intestine were determined by examination of the large intestine in 443 consecutive autopsies. All examinations were performed by the author. The results differed from all previous studies, except one. There was striking statistical agreement with this latter study which was carried out in Vienna over 30 years ago. Only in these 2 studies was there a prospective examination of adequate material by a single, experienced prosector. Findings in the 2 studies probably indicate the actual distribution and incidence of adenomatous polyps in an autopsy population. The incidence of polyps is 30% in the 50-60 age group and reaches a level of 50% to 60% in the 60-80 age group. The distribution of polyps in various large bowel segments in the age group 60-80 differs from that of carcinoma and is contributory circumstantial evidence against carcinoma deriving from adenomatous polyps.

The Physician's Workshop

A New Instrument for Obtaining Bone Marrow for Biopsy

ALTHOUGH THERE are various tools for obtaining a marrow sample during life, a need exists for a device which allows interchange of different gauge needles and yields an undistorted marrow core when aspiration fails. The instrument shown in Figures 1 to 3* accomplishes these purposes.

The Instrument

The instrument is made up of two units: "the marrow aspiration instrument" (Figures 1 and 2) and the "tissue core instrument" (Figure 3). The marrow aspiration instrument has four parts — the cap, body, support with chock, and shield with a straight and rounded flange. The unit is equipped with three aspiration needles, a 13, 15, and 17 gauge, each three inches long with a matched bevel point stylet (Figure 2).

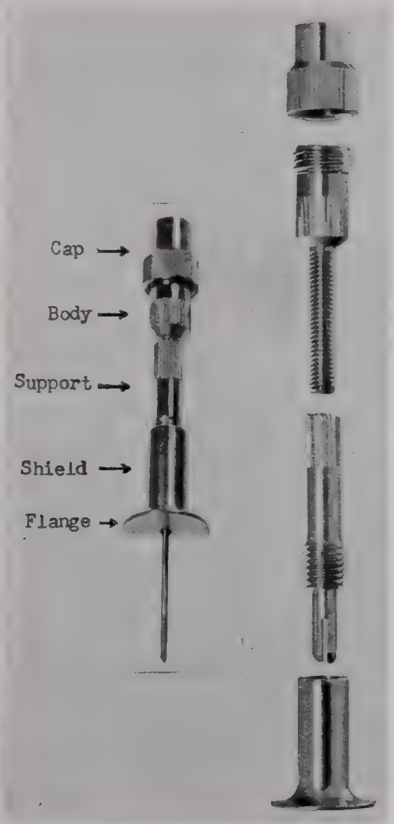

Fig. 1 — Left to right. Assembled marrow aspiration instrument. Disengaged instrument showing its four parts: the cap, body, support with chock, and shield with straight and round flange.

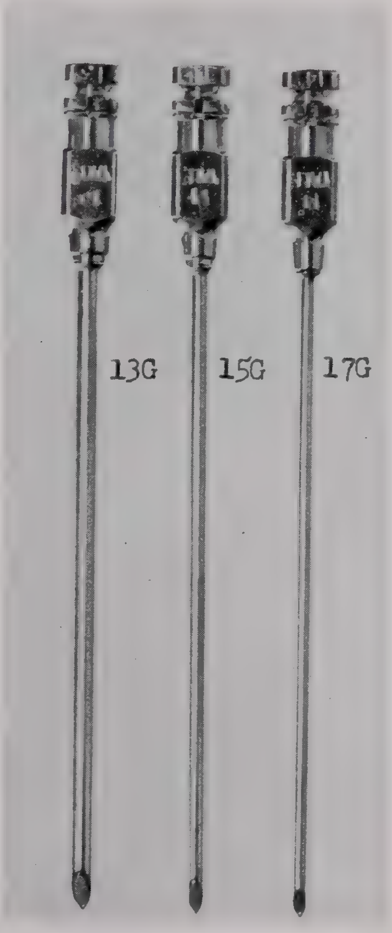

Fig. 2 — Interchangeable aspiration needles 13, 15, and 17-gauge.

Continued

---

*Schleicher Marrow Aspiration and Tissue Core Instrument made by Becton, Dickinson and Company, Rutherford, New Jersey 07070.

The Tissue Core Instrument

The tissue core instrument (Figure 3) has three parts, a blunt end stylet, a detachable hub with a set screw, and a 11.5 cm. long disposable core shaft with a razor-sharp bevel. When the core shaft is completely inserted in the hub, the bevel extends 3 mm. beyond the bevel of the aspiration needle. The core shaft, however, can be lenghtened about 1 cm. with the aid of the set screw. The 15, 17 and 19-gauge tissue core instrument shown in Figure 3 fits into the lumens of the 13, 15, and 17-gauge aspiration needles respectively.

The Aspirating Needles

The different gauges of aspiration needles were selected to accommodate the user. A 13-gauge needle is preferred for penetrating the femur, the lumbar vertebrae, and the iliac crest. A 15 and 17-gauge needle is generally used for obtaining a marrow sample from other sites of the skeleton.

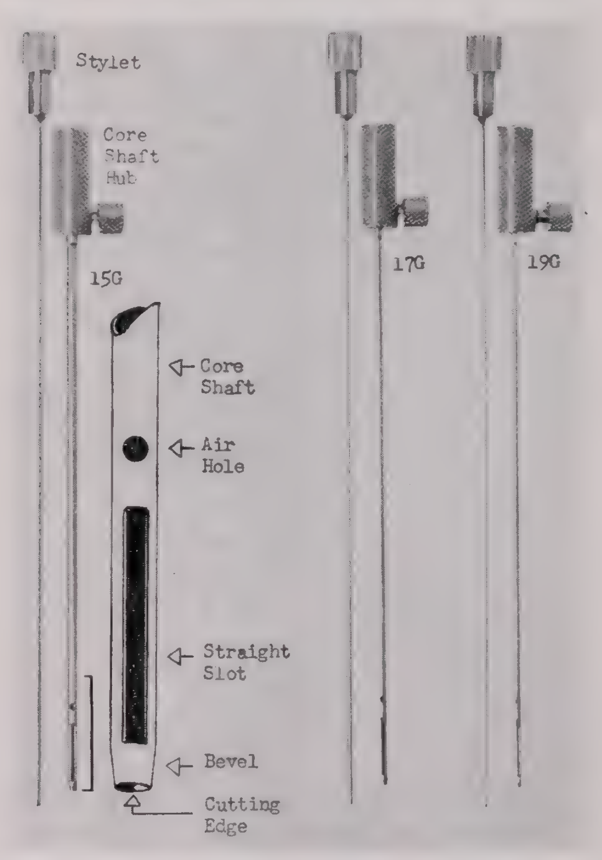

Fig. 3 — Tissue Core Instrument 15, 17, and 19-gauge fitting the lumen of the aspiration needles 13, 15, and 17-gauge in the order given. Drawing shows part of the core shaft, the air hole, straight slot, and the bevel of the tissue core instrument.

Function of the Marrow Aspiration Instrument

The instrument is 7 cm. in length. The design allows a secure grip on the instrument. *The cap* holds the stylet of the aspiration needle firmly in place, preventing dislodgment when the skin and bone are penetrated. The hub of *the body* keeps the aspiration needle hub from turning, and the thread part permits adjustment of the needle length beyond the shield. One complete turn of the body equals 1 mm. The long groove on the body hub serves as a turn indicator. Thus it is possible to accurately adjust the length of the aspiration needle and depth of the bevel in the medullary cavity.

The support together with the shield secures the aspiration needle by turning the support clockwise into the shield. Thus the chock of the support is forced against the conical inner wall of *the shield.* This action results in fastening, stabilizing, and centering the needle in the instrument, a desirable feature because it distributes stress evenly and prevents bending of the needle on hard bone. Though the aspiration needle is tightly secured, the length protruding from the shield can still be adjusted, a feature which is particularly important when the instrument is in situ and bone trabeculae must be broken to obtain a good flow of marrow substance into the syringe. *The flange* of the shield serves as a finger support and minimizes embedding of the shield into the skin. The straight part of the flange allows insertion of the instrument at a 10° to 15° angle, a position used to obtain marrow from ribs, from osteoporotic bones, and from the newborn and the infant. The 15 or 17-gauge needle may be shortened to 2½ inches for exclusive use on the newborn and the infant.

Determining the Length of the Aspiration Needle

The distance the aspiration needle protrudes from the shield is determined before the instrument is inserted into the medullary cavity of the selected bone by passing a small-gauge needle through the skin to the bone surface. The length of the aspiration needle is adjusted by turning the body clockwise or counterclockwise till the length corresponds to the determined distance. The needle length is then further advanced to compensate for the thickness of the anterior lamina of the bone. For example, the anterior lamina of the sternum is 0.8 to 1.5 mm. thick. Thus two complete turns of the body, which equal 2 mm., correct for the lamina thickness. To make sure that the bevel of the aspiration needle will be in the medullary cavity, 1 mm. of length is added (one complete turn of the body). Since the medullary cavity is only 6.0 to 9.0 mm. in depth it is necessary to adjust the length of the needle with care. The straight part of the shield flange should be parallel to the manubriosternal ridge when the instrument is in situ. Turning the aspiration needle several times up and down within the added 1 mm. creates a channel in the trabecular framework that aids in obtaining marrow substance.

Function of the Tissue Core Instrument

The total length of the tissue core instrument is 13 cm. The hollow *core shaft* has a 1 cm. long *straight slot,* an *air hole,* and a razor-sharp *bevel.* The core shaft is secured in the hub with the set screw, which also allows the core shaft to be lengthened about 1 cm.

When a dry tap is experienced the needle of the marrow aspiration instrument is left in situ and the syringe disengaged. The tissue core instrument of corresponding size is then inserted; for example, if a 15-gauge needle is in the instrument the 17-gauge tissue core instrument is used. If a tissue core of more than 3 mm. in length is desired, the core shaft is adjusted accordingly and again secured in the core shaft hub with the aid of the set screw. The core shaft is then passed through the lumen of the aspirative needle. When resistance is felt, the core shaft is gently pressed into the marrow parenchyma while rotating the shaft clockwise. Thus the razor-sharp bevel readily cuts trabeculae, fibrous tissue, marrow, and tumor. That the core shaft may cut through the posterior lamina of a bone is remote, since solid bone tends to dull the cutting edge of the bevel. When increasing resistance is encountered the core shaft is rapidly turned several times and withdrawn.

Irrespective of the kind of specimen obtained, the core shaft is released from the hub and placed immediately in formol-saline fixing fluid* for one hour. The slot and the air hole permit the fixing fluid to come into immediate contact with the marrow sample; thus artefacts are minimized. Since tissue tends to shrink somewhat during fixation the specimen is easily removed from the lumen of the core shaft with the blunt-end stylet. Because the labile tissue core is retained in the cannula until properly fixed, the possibility of damaging the histology

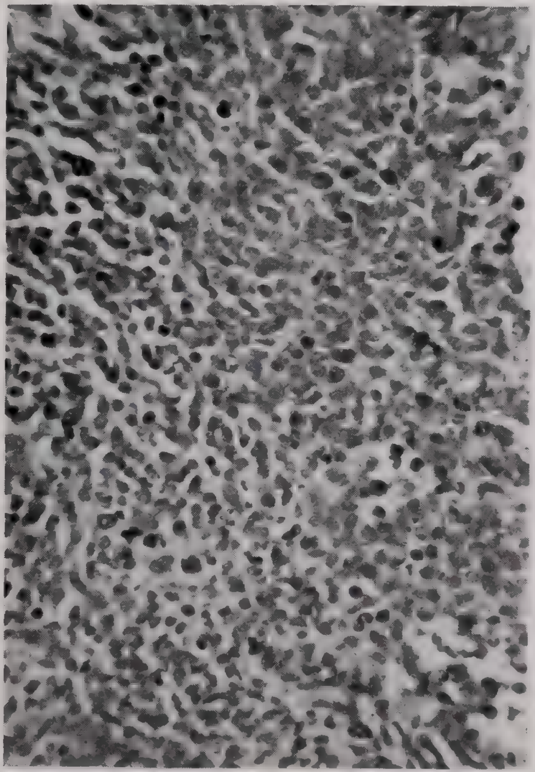

Fig. 4. — Part of a histologic marrow core preparation of a nonaspirable tumor. The specimen was obtained with the 17-gauge tissue core instrument.
Magnification x 500
Hematoxylin-Eosin stain

Continued

---

*Neutral Formaldehyde	10 ml.
Physiologic Sodium Chloride Solution	90 ml.

while expelling the specimen is remote. A second unfixed sample may be used for imprint or smear preparations.

Should solid bone in the core shaft bevel prevent the specimen from being expelled, the bone disc is gently pushed into the lumen. If force has to be applied to move the bone disc, the latter is pushed along the lumen expelling the sample from the other end of the core shaft. This procedure does not cause distortion of the histology of a well fixed core. Figure 4 shows part of a histologic preparation of a tumor core obtained with the 17-gauge tissue core instrument.

The tissue core instruments can also be used for obtaining a specimen from other soft organs.

Method of Testing the Sharpness of the Core Shaft Bevel

Razor sharpness of the core shaft bevel is absolutely essential for obtaining an undistorted marrow core. Thus the cutting edge must be tested after each use and before sterilizing the instrument. This can be done in a simple manner. Fold a sheet of Kleenex tissue several times; then rotate and slightly press the shaft against the tissue. A sharp bevel readily cuts into the paper cushion with smooth-edged discs retained in the lumen of the bevel. If no discs are obtained the bevel edge may be sharpened on emery paper No. 000 or honed.

Summary

A new instrument is presented for obtaining a marrow sample for biopsy. The instrument consists of two units: a marrow aspiration instrument and a tissue core instrument. This versatile tool allows procuring of a marrow sample from different sites of the skeleton of all age groups. It provides an undistorted specimen when a so-called dry tap is encountered. The components of both units and their proper use are described.

Amiel's Grievance

The principal grievance which I have against the doctors is that they neglect the real problem, which is to seize the unity of the individual who claims their care. Their methods of investigation are far too elementary; a doctor who does not read you to the bottom is ignorant of essentials. To me the ideal doctor would be a man endowed with profound knowledge of life and of the soul, intuitively divining any suffering or disorder of whatever kind, and restoring peace by his mere presence. Such a doctor is possible, but the greater number of them lack the higher and inner life, they know nothing of the transcendent laboratories of nature; they seem to me superficial, profane, strangers to divine things, destitute of intuition and sympathy. — Henri-Frederic Amiel (1828–1881)

Tribute from a Thinker

But nothing is more estimable than a physician who, having studied nature from his youth, knows the properties of the human body, the diseases which assail it, the remedies which will benefit it, exercises his art with caution, and pays equal attention to the rich and poor. — Voltaire

Space Laboratories for Research in Biology and Medicine*

Promising Developments

MAJOR GENERAL OLIVER K. NIESS**
Colorado Springs, Colorado

THE STUDY of life, its origin, preservation, support, texture, composition, chemistry, physics, and evolution has been the occupation of researchers in biology and medicine for centuries past. Life in all its forms has been studied, classified, dissected, and probed for knowledge, understanding and exploitation by man. The biological objects of study have been those adhering to the surface of the earth, immediately above or below, and limited by the physical constraints of that environment.

Man has wrested many of nature's unyielding secrets from living tissue by varying in the laboratory the environmental effects, temperature, radiation, sound, light, and other electromagnetic forms of energy. By changing these energy forms in biological tissue, he has been able to manipulate the living cell, to disrupt its motion, scatter molecules, and force the life form in one fashion or another to reveal its structure.

Manipulating life forms for research with various energy probes is expensive and often difficult because living tissue is easily damaged and changed to nonliving tissue and is tightly bound to the physical constraints of the surface of the earth.

The U.S.S.R., in its space program, has placed a heavy emphasis on biology in space. As related by Parin, "In addition to the dogs, mice and flies were sent into space. Flies are quite sensitive to the effects of radiant energy and a great many could be sent along on the flight."

. . . "As we know, radiant energy, including cosmic rays, is deceptive. Its effects are not felt immediately, but after some time, depending on the intensity of the irradiation to which the organism is subjected.

"The marrow tissue of mice, most sensitive to the effects of radiation, was studied and it was found that there were no harmful

effects on the hemopoietic system. The blood composition also remained normal. Genetic experiments, too, were conducted on the flies."[1]

In addition, the space ships carried plant seeds and shoots. It is interesting that cosmic radiation had a positive effect on the shoots; growth was accelerated.

Manned Orbital Space Station

The manned orbital laboratory task is not to prove that man can orbit the earth in space and survive to return; Mercury and Vostok proved that; but the task is to deploy a laboratory so designed as to make possible basic research on the performance potential of man in space. This mission requires that the exploratory laboratory maximize the research potential and minimize the disadvantages which will prevail in this essentially foreign environment for earth-man scientists. What is called for is an operational space laboratory.

Manned orbital space stations are only a particular mode of space operations, but in the next ten years they will play a dominant role in the development of space research and development laboratories. The space environment has been closely approximated at ground level with three important exceptions: the gravity-free state, the ionizing radiation component, and an infinite unimpeded heat sink.

The Mercury and Gemini projects have provided important data and information for short-term exposures to space. Apollo will provide additional data, but space stations will be the facilities in which the effects of prolonged exposures of months and years can be investigated, and at the same time include provision for the health and performance needs of man.

Biotechnologist

Biotechnological research in manned orbital stations will be designed so that programs: (a) include those which can be effectively executed only in true space or in a weightless state; (b) apply principally to requirements in such areas as design, health, safety, and performance; (c) meet specific needs of national interest; and (d) justify their cost in terms of extent of need for such information and in terms of over-all usefulness.[2]

Many of the experiments will have to do with performance of the manned versus the unmanned system, others with basic areas where man may do better as an investigator and data-acquirer than unmanned probes. Throughout, the laboratory research will be done on earthman himself as a subject in the space environment and, finally, the entire program will be designed to contribute to the follow-on space project.

Essentially, the designer's task will be to:

(1) provide the manned orbital laboratory with an environment which will contribute to and least interfere with research,

(2) provide the manned orbital laboratory with the tools and instruments necessary to conduct required experiments,

(3) provide the manned orbital laboratory with a data system that can manage acquired data, and

(4) provide the manned orbital laboratory with the systems support which will make possible the determination of the potential of manned versus unmanned space systems.

Man vs. Instrument

Comparison of man and instruments for information gathering at the level of raw data puts the human in a highly unfavorable position. In general, instruments are more accurate and more sensitive and can be endowed with much better memories.

Complex Pattern Recognition

Man does have a flair for complex pattern recognition, but this is offset by his gross limitation on processing rate. The most optimistic measurement of human information acceptance rates leads to a figure of around 35 bits per second. Some more stringent tests have suggested rates as low as four or five bits per second. These figures are about six orders of magnitude less than the 5 x 10^7 bits per second rate of a television channel. For elementary processing such as arithmetical operations or simple sorting, computing machines are again faster by factors around a million.

If we are to justify transporting a man into space, we must find a part for him to play beyond sensing or processing. Man has his ability to use language. To compress a vast amount of data into a few symbols is incomparably beyond the capabilities of mechanical coding techniques for communications or programs for computers. In some contexts it is true that a single picture is worth a thousand words. It is also true that in other contexts a single word can sum up a thousand pictures.

Novelty Interpretation

The other characteristic of man that recommends itself is his ability to recognize and interpret novelty, to see significance in small deviations from the ordinary. This quality enabled Volta to notice a frog's leg twitching and surmise that it was a sign of chemical involvement with electricity and caused Fleming to interpret a bit of mold in his bacteria culture as something other than a contaminant. In a more modest fashion the same phenomenon was at work in singling out the "Glenn effect." This ability is no better understood than the powerful coding effect of language. Worse, it is even less controllable. For the one instance where a Fleming sees a new effect, hundreds of technicians have poured the mess down the drain. Putting a man in a spaceship does not guarantee that he will experience serendipity. On the other hand, not putting him there virtually guarantees that the novelties will be missed.[3]

The law of geotropism says that in a plant, when the seed germinates, the roots will grow down and the stem up.

What will it do in Zero-G? Will roots grow all around? As yet we do not know. The molecular behavior of liquid and gas in the cell membrane and all around it will be altered in Zero-G. How this will affect the cell and its basic processes we do not know.

If there are life forms on Mars that are very similar to life forms on Earth, then Gulliver is likely to report them; but if there are life forms whose metabolism is like nothing on earth, we will have to rely on our astronauts.

Space Laboratory

The space program will make available to the researcher in life forms a laboratory of energy around which he can re-examine the entire spectrum of basic assumptions and

EARTHMAN'S LIFE ZONE EXTENSION BEYOND EARTH'S SURFACE USING MISSILE/ SPACE/LIFE SUPPORT SYSTEMS

Fig. 4 — Anticipated Expansion of Earthman's Knowledge in Science and Technology from the Manned Space Laboratory Research Program. Fig. 4 illustrates this quantum jump in the capabilities of man's mind which will occur from our space explorations and which will profoundly affect our sciences and technologies and biomedicine. On the left we show the limits, the constraints on man's inquisitive intellect; for, as the Apostle Paul said, "Now we see through a glass darkly, then face to face." And, indeed, the heavens will open to us in the space program.

Continued

facts which man has gleaned from centuries of painstaking study. For the first time he will have at his disposal a laboratory for life forms beyond the surface physics and chemistry of this earth.

This laboratory of such penetrating energy and varying physical constraints can be expected to bring about a leap forward in man's understanding of life and of the basic sciences themselves, which are all avenues for the understanding of life and its structure.

As never before, we are also beginning to grasp the severe limitations of earth-bound "brains" and thought. Historically, the best minds of men have applied their energies vigorously to these problems, and in some perplexing areas results have been almost always negative.

Human beings are two-dimensional creatures tied to a surface of positive curvature by gravity. We live at the interface between a layer of gas and a layer of solid and liquid. It is only in the past half century that we have begun to move away from the interface, upward and downward with minor oscillations. In the next decade radical departures from our billion year environment will be attained.[3]

If one examines the swift changes which have rapidly carried science and technology ahead in the past few years, further than in previous decades or centuries, it is evident that the mind of earthman enlarges its scope to every facet of its known world. When this level is attained, exploited, and understood, a plateau is reached until some vehicle or communications link, or sensor, can bridge the gap between the known and the unknown.

For earthman space is becoming an opportunity for the analysis of terrestrial science against the backdrop of extra-terrestrial forces. The manned space laboratory program will provide the tools, instruments, experiments, scientists, and support systems for conducting this exploration.

The vast accumulation of data from space explorations will be quickly assimilated by man's mind and the next step forward in science and technology will be under way.

The philosopher Kant pointed out that all the things we know for sure are things which the mind imposes on our picture of the world. He was vague on details of how this imposition occurred or what determined the structure. Kant and most philosophers have felt that there was some special necessity about the categories or mental molds into which we poured our knowledge of the world. More recent studies by psychologists and sociologists suggest that these molds are at least partly conditioned by environment. There are fascinating hints by psychobiologists that certain mental frames may be hereditary and represent a form of biological learning that is as subject to natural selection as tooth size or running ability.

I would like to quote a section of the article entitled "Brain" in the Ninth Edition of the Encyclopedia Brittanica by the great brain surgeon, Sir Charles Sherrington. The section is entitled, "Had Man Had Wings," and the entire section is written with the same harsh magniloquence.

"An interface from the course of evolution of the vertebrate brain is that the freeing of a limb-pair for more manifold use as a 'tool' while the other limb-pair, still assured efficient land locomotion, gave an impulsion or opportunity for cerebral development which was of decisive importance in the evolution of pallial growth and function. This inference raises the surmise that, had wings arisen in the vertebrates, as actually in the insect, without cost of a limb-pair to coexist with 'land-locomotor,' the leg, and 'tool,' the arm, the consequent additional experience and exploitation of a great three-dimensional medium (containing, unlike water, ample oxygen), then would have evolved a brain of wider components and on fuller lines than is the human. A sobering reflection is that should such a vertebrate form, fraught with transcendent promise though it were, enter now upon evolution, man's dominance, leaving no part of the planet's surface untouched, would assuredly meet it and frustrate it by extermination, or by domestication. . . . It would look as though after all, the upward development of mind were not (at least on this planet) an object of the scheme of things."

Sherrington was trying to imagine a mind less hampered than his own. It is no wonder his rhetoric is labored and his thoughts tortuous. Nevertheless, his attempt was in itself a partial counter to his own point. Man appears to have been endowed with a brain richer than his limited experience.

Up to now we have learned most of what we know about the universe beyond the lower atmosphere from light signals, plus an extrapolation of what we know from earthbound laboratories. In recent years other segments of the electromagnetic spectrum have been added, and some information has been gleaned from the debris of cosmic rays. It is amazing how much has been inferred. Light is a remarkably rich carrier of information once the code is broken. But we have been like goldfish in a bowl, attempting to reconstruct what goes on in the bigger world from filtered and refracted images.

Much of the complexity of what we perceive, the structure of things, is furnished by eyes and ears. However, the sense of reality is established by the cruder senses: touch and the kinesthetic feelings. Space flight will allow the analog of touching what we have only been able to see, of realizing what we have only been able to infer, and bringing those "maybes" into the world of solid reality. The probabilities are that a transformation of world view will occur at least as dramatically as the Copernican and Darwinian revolutions.[4]

Summary

Beginning with the manned orbital laboratory, space science will assume a new dimension — that of research in human performance potential and in biology and medicine. Earlier spacecraft determined if manned flight was possible and, if so, to prove out systems to make the flight possible.

Space laboratories will provide a unique test and research environment for biology and medicine, due to the drastic changes in force fields of gravity, time, space, and energy constraints under which all things live on the planet's surface. This laboratory will make possible not only entirely new and unpredictable advances in understanding by man, but coupled to all of the other accomplishments of man's brain will be a quantum jump in the evolution of new understanding.

No one can foresee how fast or how far space research will carry biology and medicine. To date, most of the fallout from missile and space programs has been peripheral, that is, applications of systems primarily developed for weapons. Now with the manned orbital laboratory, the object is the discovery of new data on life, on man, and on all of his performance potential, the greater share of which will be in his "brain" in the new dimension of space.

Admittedly, there exists a weapons potential in space, but the results of these laboratory investigations will likely have their most profound effect in helping man to unravel many of the puzzling problems in biology and medicine right here on the surface of the earth.

History of Medicine

Dilatation of the Heart*

P. E. SHEPPARD, M.D.
Hutchinson, Minnesota
Written 1900

WITHOUT THE least claim to originality of research or anything new to present in the line of treatment, I will briefly outline the subject of dilated heart.

I believe it to be a subject of interest to all who practice medicine, and an occasional review is profitable.

A study of cardiac dilatation cannot be separated from that of hypertrophy, for these two usually go hand in hand; but dilatation is a condition well worth consideration by itself and has a chain of symptoms all its own.

Three forms are recognized:

1. Simple dilatation with little or no change in the wall;
2. Hypertrophic or active dilatation (the most common form);
3. Atrophic or passive dilatation.

Morbid Anatomy

The structural changes depend upon the morbid processes which attend the dilatation. From pericarditis and endocarditis there will be serious infiltration and granular degeneration of the muscle fibers. As the result of fatty degeneration the muscles show fatty changes.

The morbid gross anatomy depends largely upon the mechanical condition, and the shape and outline depend upon the part involved. If the dilatation is confined to the right ventricle the heart will increase in breadth; while if confined to the left ventricle the heart will be elongated, with the whole organ affected as in aortic insufficiency.

The endocardium is often opaque. The trabeculae may be reduced to mere fleshy tendons. One or all of the heart cavities may be the seat of dilatation: most commonly the auricles, next the right ventricle, and least frequently the left ventricle (Loomis).

There is always more or less relative insufficiency of the valves from simple separation.

Etiology

Dilatation may take place, first from any cause which may weaken the heart, such as inflammatory conditions or degeneration of the heart itself, or from constitutional states and acute diseases such as pneumonia, typhoid, etc. Such may be termed primary dilatation. Second, all the causes of hypertrophy, when acting on a weak heart, may cause dilatation. They are mostly obstructive in their nature and include valvular stenosis and insufficiency, atheroma and renal disease.

Such dilatations are preceded by hypertrophy and develop as degeneration sets in or may occur acutely on overstrain, fright, etc.

Obstruction

A glance at the mechanism of the heart will serve to show how obstruction and valvular changes can bring about dilatation of the several cavities. Beginning at the left ventricle and going backward we first find heightened systemic blood pressure, which throws the burden of the work upon the left ventricle. To meet this increased demand of

Continued

This paper was written by P. E. Sheppard, M.D., Hutchinson, Minnesota, who was a member of the first graduating class of the University of Minnesota. He started in 1889, was graduated in 1891, and wrote the paper about 1900. This was found among some of my mother's possessions in November 1963. — Charles G. Sheppard, M.D., Le Sueur, Minnesota.

force, hypertrophy occurs, and when the muscle can no longer compensate, dilatation follows.

Aortic Stenosis

Aortic stenosis brings about a similar chain of results. As the left ventricle fails, the increased pressure is backed up into first the left auricle, accompanied by relative insufficiency of the mitral, next, from ensuing pulmonary engorgement into the right ventricle; then the right auricle follows in yielding to the morbid process. Beginning with mitral insufficiency a similar chain of events ensues.

Mitral Stenosis

Beginning with mitral stenosis the picture is altered inasmuch as the left ventricle is left unchanged or even atrophied from insufficient work to do and lack of blood supply. The rest of the heart may then take the usual course of hypertrophy and dilatation.

With pulmonary obstruction the left heart is practically left out of the process; the right only suffers. Thus the disturbances may be traced back to the inflowing blood from the venae cavae.

Symptoms

Pain is not a prominent symptom but may be quite severe and radiate down the arms, especially the left arm. Palpitation is often complained of. A feeling of undefined distress and pressure may be present, and there is a tendency to sighing respiration. Dyspnoea on slight exertion is noted and later becomes very distressing, especially at night, so that the patient is obliged to sleep in a semi-recumbent posture or sit with the head resting on the arms. As the trouble increases the patient's countenance assumes a pale, anxious expression with more or less lividity of the lips. The extremities are cold.

Dyspeptic symptoms are often present and there is more or less mental disturbance. The urine becomes scanty and there is more or less albumin. There will be puffiness of the ankles and later general anasarca. Respiration becomes rapid, 30 to 40 to the minute, and speech becomes difficult from shortness of breath. Paroxysms of dyspnoea are frequent and syncope may be fatal. The patient usually dies from general anasarca or pulmonary edema.

Physical Examination

Physical examination reveals an enlarged and diffused area of cardiac pulsation, and it is difficult to locate the apex beat. Epigastric pulsation occurs in dilatation of the right ventricle. Palpation shows the feebleness of the heart action, an undulating motion, and perhaps a purring thrill. Percussion shows a greatly increased area of dullness which may extend from the right nipple to the left axilla. Dilated auricles may be recognized by an upward increased area of dullness.

The sounds of a dilated heart are weak and indistinct, it being often difficult to distinguish the first from the second sound. Murmurs are confused and uncertain.

The Diagnosis

Thus the diagnosis of dilated heart rests upon feeble heart action, undulating pulse, indistinctness of apex beat, lateral increase of percussion dullness, short, abrupt, and feeble heart sounds that strikingly resemble each other, a feeble, irregular, intermitting pulse, accompanied by the general symptoms of pulmonary and systemic obstruction and congestion.

Prognosis

Prognosis depends upon the removability of the cause, the age of the patient, etc., but should always be looked upon as grave.

Treatment

Treatment resolves itself into the treatment of the primary cause and attention to the symptoms. For the dilatation itself rest of body and mind are essential and attention to general body nutrition is important. A few days or weeks in bed will in many cases give great relief. An exclusive milk diet will often do much good and stimulants should be avoided. The patient should be warned against sudden physical exertion. Flannel should be worn next to the skin.

Besides digitalis, iron and strychnine are the most useful drugs. The cold bath seems to have a decidedly beneficial action, probably from its tonic effect. Venesection will relieve extreme engorgement and often save life.

I wish to report a few cases that have come under my observation during the past few months.

Case Reports

Case 1

H. L., female, 14, has had several attacks of chorea since five years of age. In March 1898 the attack was accompanied by a well marked case of inflammatory rheumatism and endocarditis. In April 1899 the rheumatic symptoms were slight but endocarditis well marked, and dilatation of the heart took place. In the course of a few weeks compensation was restored and the child was able to attend school. In March 1900 dilatation reappeared with all the classical symptoms and was extreme.

With rest in bed, digitalis, cold baths, etc. compensation is partly restored and the patient is about and comfortable.

The meaning of "endocarditis well marked" is for the reader to determine. The modern physician would have included an auscultatory description of the heart and a plethora of laboratory studies, but he could not improve upon the result: "about and comfortable." Editor: R. B.

Case 2

E. S., male, 63, came under my observation in February 1900. He was a subject of chronic Bright's disease. Heart action irregular but fairly good. Chegas Stokes respiration. Hypertrophy of heart well marked.

General anasarca was extreme. This was completely reduced by elaterium* and wet packs and the patient was in a condition of comparative comfort up to April 18 when he died from acute dilatation in about one hour from beginning of attack.

Blood pressures were not routinely measured in 1900. The patient was probably fibrillating, and digitalis might have proved life-saving. The editor has had no experience with elaterium. Editor: R. B.*

Case 3

L. D., male, 56, apparently in perfect health up to last February when he had an attack with weakness, constipation, dyspnoea, and an extremely slow pulse, 40 to 45. No pain. Recovery was not complete. I saw him first on July 6, 1900. Found respiration 38 to 40, pulse about 70, weak, irregular, and intermittent. Rales and dullness over lower and middle lobes of right and lower of left lung. Urine contained considerable albumin. No casts could be found.

Right heart dilated and a relative regurgitant-tricuspid murmur. Apex in 6 intercostal one inch to left of nipple. Some mental disturbance.

Patient was taken to Dr. J. W. Bell of Minneapolis who found fluid in the right pleural cavity. No history of pleurisy, no pain at any time. Symptoms now improving under rest and digitalis.

He might have been a candidate for a pacemaker. Editor: R. B.

I select these three cases because of the variety of etiology to result in the same lesion.

Sceptical France

Even if doctors apply all their knowledge, and act in good faith they often do harm when they think to do good and do not perceive their mistake until the patient has passed beyond . . .

The ignorance of many so-called doctors we know to be so great that it would provide subject matter for a large volume . . .

I should add a word about . . . surgeons; nothing new certainly, for every day we hear many accusations against them; that they carry on to twenty or thirty dressings what could be finished at the third or fourth: that they prolong wounds and sometimes stir them up instead of healing them; and that their wretched ignorance often makes it necessary to amputate an arm or leg. — Estienne Henri (1528–1598)

Life is compatible with any disease, provided the bowels remain open; any kind of pain, provided the heart remains unaffected; any kind of uneasiness, provided the head is not attacked; all manner of evils, except it be a bad woman.

— The Talmud

One third of the people in the United States promote, while the other two thirds provide. — Will Rogers

"The Measurement of Depression"

"THE MEASUREMENT OF DEPRESSION" is a film* depicting the development, validation, and use of a scale for the quantitative measurement of depression.

The scale was designed by Dr. William W. K. Zung[1] Durham, N. C., psychiatrist. Although initially devised for use in psychiatric research, it readily lends itself to the general practice of medicine where most depressions are first encountered.

The film is designed for medical educational purposes at meetings of hospital staffs, county societies or specialty groups. The self-rating scales, available in quantity for use in office practice, come complete with full instructions. Both the film and pads of the self-rating scale are available free upon request from Lakeside Laboratories, Inc., Milwaukee, Wisconsin, 53201.

The scale consists of a list of 20 statements expressed in the common language of the patient. The statements comprehensively delineate widely recognized symptoms of depression including disturbances of mood, biological and psychological function. Testing and scoring patients usually requires less than five minutes. Use of the scale in a variety of patients with physical complaints without apparent organic basis may uncover and measure depression in so-called "hidden depressions" saving valuable time in the clinic and several sessions of probing interviews.

In patients in whom depression is suspected, but is obscured by anxiety or by normal grief, the scale can be used to provide a quantitative index of depression which may be compared with depression ratings obtained in hospitalized and office patients with a variety of emotional disturbances.[1,2]

Depression is a condition of paradox and contradiction. It is sometimes a self-limiting disease with a duration of six to eighteen months, but it may persist for years. It may be obvious or be hidden — from the patient and from the physician.

The depressed patient's grasp of reality usually appears to be undistorted. Even so, suicide makes it necessary to classify depression as a potentially fatal disease. Depression is today's most common and most challenging diagnostic problem, in psychiatry as well as in the general practice of medicine.[4] Despite its high incidence and much that is known about it — the diagnosis of depression often requires from months to years.[3]

---

*Running Time: 22 minutes. 16 mm., sound and color. Produced by: Sturgis-Grant Productions, Inc. Sponsored by: Lakeside Laboratories, Inc. The film is available on loan without charge. To schedule a showing of THE MEASUREMENT OF DEPRESSION, please see your Lakeside Professional Service Representative or write or phone Medical Film Department, Lakeside Laboratories, Inc., 1707 East North Avenue, Milwaukee, Wisconsin 53201.

CHARLES ROGER SULLIVAN, M.D.

Dr. C. Roger Sullivan, 44, a member of the Section of Orthopedic Surgery of the Mayo Clinic from 1955-1966, died July 3, at Augusta, Georgia, of the attendant effects of pneumonia. He was a member of the faculty of the Medical College of Georgia.

Dr. Sullivan was born in Cincinnati, Ohio, and received his degree of doctor of medicine from the University of Rochester School of Medicine and Dentistry. He came to Rochester, Minnesota, in January, 1951, as a fellow in orthopedic surgery of the Mayo Graduate School of Medicine. In 1954, he was appointed an assistant to the staff of the Mayo Clinic, and in 1955 he was appointed to the staff of the Mayo Clinic. Dr. Sullivan was certified as a specialist in orthopedic surgery in 1956 by the American Board of Orthopaedic Surgery.

In 1966, he left the Mayo Clinic to become a member of the faculty of the Medical College of Georgia at Augusta. Dr. Sullivan was a fellow of the American College of Surgeons, a member of the Zumbro Valley Medical Society, the Southern Minnesota Medical Association, the Minnesota State Medical Association, the Minnesota-Dakota-Manitoba Orthopedic Society, the American Medical Association, Orthopedic Research Society and the Alumni Association of the Mayo Graduate School of Medicine.

Dr. Sullivan is survived by his wife and six sons.

MYRON W. SMITH, M.D.

Dr. Myron W. Smith, 94, physician and civic leader in Red Wing for more than half a century, died June 14, at the Colonial Acres Nursing Home in Golden Valley. He was born in Rockford, Illinois, and received his medical degree from the Boston University School of Medicine.

Dr. Smith was president of the first Goodhue County Sanatorium, a past president of the Goodhue County Medical Society, Goodhue County Soldiers Memorial Association and the Goodhue County Historical Association. He was a life and 50 Club member of the Minnesota State Medical Association and a member of the American Medical Association.

He is survived by his three daughters.

CLAIR C. CRAIG, M.D.

Dr. Clair C. Craig, 89, International Falls physician, died May 15. He was born near Elk River, Minnesota, and received his degree in medicine from the University of Indiana. In 1917 he went to International Falls to become associated with Dr. Mary Ghostley. In 1920 he opened up his own private offices.

He was a member of the Upper Mississippi Medical Society and American Medical Association and a life member of the Minnesota State Medical Association. Dr. Craig was also a member of many civic organizations in International Falls.

He is survived by his son and two daughters.

ARMER H. STOLPESTAD, M.D.

Dr. Armer H. Stolpestad, 57, St. Paul physician, died May 31st. Born at Lafayette, Minnesota, Dr. Stolpestad practiced on the East Side of St. Paul for thirty-one years. He received his medical degree from the University of Minnesota medical school, and interned at St. Mary's hospital in Duluth.

He was a member of the Ramsey County Medical Society, Minnesota State Medical Association and the American Medical Association.

He is survived by two daughters and two sons.

SIDNEY C. BLACKMORE, M.D.

Dr. Sidney C. Blackmore, 53, medical doctor at the Erie Mining Company in Biwabik, died July 3. Born in Rainy River, Ontario, Canada, he lived in Duluth for some time and graduated from the University of Minnesota Medical School. He moved to Biwabik in 1946 and in 1954 joined the East Range Clinic in Aurora.

He was a member of the Range Medical Society, American Medical Association, Minnesota State Medical Association and was a past commander of the Knights Templar Lodge of Eveleth.

He is survived by his wife and three sons.

PRODUCT NEWS

Pentyex-MPL

As we study the geriatric patient, we find many of them require a cerebral stimulant for sustained treatment. Some of these patients are mildly confused, have memory defects and apathy. The action of the ingredients supplied in Pentylex Elixir has proved 100 per cent effective in over two-thirds of the patients treated on a continuing basis with pentylenetetrazol alone. Pentylex Elixir supplies (in a fine wine base) not only pentylenetetrazol but also thiamine, niacinamide and cyanocobalamin, other essentials often required by these patients.

Minnesota Pharmaceutical's Pentylex is also available in an injectable form which includes the liptotropic factors of choline, methionine, and inositol as well as B-12 and other B-complex factors.

How Much Fidelity Bond?

Even with the most trusted employees, and under the most ideal system of internal control, employee dishonesty can and does occur. With a system any less than ideal, an employer may, in fact, be encouraging such dishonesty. It is also a time-worn fact that embezzlements occur in places and at times where they are least expected. The Fidelity and Deposit Insurance Company estimates losses from employee dishonesty at $500,000,000 annually. Thefts range from insignificant amounts up to thousands of dollars, occasionally a sum adequate to bring about complete financial ruin to an employer or firm.

In addition to providing decent working conditions, reasonable hours, adequate wages and opportunity for advancement, employers have a moral obligation to safeguard their employees' integrity by doing everything possible to deter them from yielding to the temptation to embezzle or steal. No system of accounting or internal control has yet been devised which will absolutely guarantee against dishonesty, yet much can be done to keep an inherently honest employee from yielding to temptation in a moment of weakness, or under the stress of financial worry.

Following are some important features of an adequate internal control system. If at least some of these points are not operative in your office, you should discuss them with your management consultant or accountant:

1. Is the mail opened by a trusted employee, *other than* your bookkeeper or cashier?
2. Is a list of mail receipts, classified as to checks, cash or money orders, prepared by this person and checked against the daybook regularly?
3. Are receipts issued for all monies received and are all unused receipts accounted for as they are used or spoiled? Receipts should be serially numbered.
4. Is cash reconciled or balanced daily and subject to check by other than the person responsible for the reconciliation?
5. Are deposits made daily of each day's cash receipts intact and responsibility fixed on one person for making these deposits?
6. Are all overages and shortages reported promptly?
7. Cash withdrawals of any type are potentially dangerous and should not be made. If such withdrawals are made, a voucher showing the amount and the date should be signed by the person receiving the funds.
8. Is cash physically safeguarded to prevent a dishonest employee from blaming "outside theft" in case of shortages?
9. Are the daybook, accounts receivable and patient case histories spot-checked periodically for discrepancies and irregularities?
10. Are all employees handling cash receipts covered by Fidelity Bond or Dishonesty Insurance?

These and other safeguards which can be installed will guarantee *maximum* protection against employee dishonesty, but, as previously stated, cannot guarantee absolute protection.

The fact that employees are covered by fidelity bond, in itself, acts as a deterrent against theft and embezzlement, since it makes the offense somewhat more serious in nature and more likely to be uncovered.

Much has been said about fidelity bond, the next problem is "how much?" After considering the matter thoroughly, we feel that the following simple formula for determining risk exposure is valid and can be used for Dental and Medical offices:

1. 10% of annual gross receipts ....$________
2. 10% of current assets (cash on hand, bank accounts, securities and drug and supply inventories) ....$________

Risk exposure ....$________

The following amounts of insurance should be carried in relation to risk exposure:

Up to $25,000	Equal to Exposure, Minimum $10,000
$25,000 to $125,000	$25,000 to $50,000
$125,000 to $150,000	$50,000 to $75,000
$250,000 to $300,000	$75,000 to $100,000

Remember, no one is immune to employee dishonesty. Your only assurance of maximum protection is a system of adequate internal control, plus bonding of each employee who has access to monies or valuable properties in your office.

Dr. William N. Spellacy, medical fellow in OB-GYN at the University, received a $45,000 grant from the Josiah Macy, Jr. Foundation.

Over 2 million mentally retarded people hold jobs. What's the world coming to?

It's getting better.

But it's still not good enough.

There are still too many retarded people doing nothing—and costing the public millions for their care.

There are still too many employers who don't realize that the mentally retarded can hold jobs that wouldn't interest most people at all. Jobs like messengers, gardeners, truck loaders, stock clerks. And the mentally retarded take more pride in their work—often have better attendance records because they like what they're doing.

In fact, if placed in jobs for which they are qualified by special training, 85% of the six million mentally retarded can help support themselves and become productive, efficient workers.

Many employers don't know this yet. Someone ought to tell them.

And for your own information, send for a free booklet. Write to
the President's Committee
on Mental Retardation,

When Ethics and Welfare Programs Clash

*Address by Arnold O. Swenson, M.D.**
First National Congress on Medical Ethics
Chicago, Illinois
March 5, 1966

IN DISCUSSING THE SUBJECT, "When Ethics and Welfare Programs Clash," we must assume that the statement is not merely a rhetorical one but an admission that indeed ethics and welfare programs have clashed in the past and probably will continue to do so in the future.

It has been my privilege to live and practice during the era which saw marked changes in the provision of medical care to the indigent. During the late Twenties the physician cared for this group of individuals as a social duty and with a devotion characteristic of the members of the medical profession.

Hospitalization was provided through county-supported hospitals or through privately-endowed welfare agencies.

As to the cost: the hospitals themselves absorbed a large proportion and prorated it among patients able to pay by averaging the daily cost of hospital care among all its patients.

With the advent of the Depression years and with the medical profession carrying an inordinate financial load in providing medical services for patients unable to pay, local and state welfare programs developed, usually with the aid of the medical profession. Services were provided at reduced cost, but also at minimum compensation to the physician rendering those services.

Section 10 of the AMA Code of Ethics states:

"The honored ideals of the medical profession imply that the responsibilities of the physician extend not only to the individual, but also to society where these responsibilities deserve his interest and participation in activities which have the purpose of improving both the health and the well-being of the individual and the community."

It was in light of this section of our Code of Ethics that the medical profession cooperated, usually with county medical authorities, in developing rules and regulations for the proper care of the medically indigent. These were trying times for the medical profession. We had governmental authorities attempting to keep costs at the lowest possible level and making rules and regulations that would hamstring the doctor in the care of his patients — all resulting in a general lowering of the medical care provided these unfortunate individuals.

Section 6 of the Principles of Medical Ethics states:

"A Physician should not dispose of his services under terms or conditions which tend to interfere with or impair the free and complete exercise of his medical judgment and skill or tend to cause a deterioration of the quality of medical care."

By devotion to the care of the sick and the insistence that the quality of medical care be not sacrificed, many long, tedious and at times frustrating negotiations with governmental authorities resulted.

In general, I believe that the physician's insistence on adequate and good medical care for the medically indigent prevailed, although there was generally a marked decrease in the pecuniary return that the physician received for his services.

There is an old saying that interest does

Continued

---

*Duluth, Minnesota.

not bind men together. Interest separates them. There is only one thing that can effectively bind people, and that is a common devotion.

This common devotion of the medical profession, more than any other factor, unified the profession in its insistence that there be no strings tied to the services formed for the indigent patient.

The doctor's devotion or consecration to the care of the sick was accepted by most welfare programs without surprise and without comment, a fact which was in itself a compliment to our group, but at the same time a source of irritation and frustration to our profession, which felt that medicine often had to bear more than its share in the care of the needy sick.

The work of the county or state medical society in its relationship to various welfare programs has had ample guidance from policy statements of the American Medical Association. The last compilation was made in 1965 and brought up to date the various policy statements in reference to the care of the needy sick by the House of Delegates of the American Medical Association, up to and including the December meeting in Miami Beach. These policy statements are familiar to most of you. If not, I suggest that you procure the latest compilation of these policy recommendations.

Now we are faced with new problems associated with the recently-enacted medicare law with its potential influence over the quality and cost of medical care. This includes both the under- and the over-65 segments of our population.

I am sure all of you here are as familiar with the provisions of Public Law 89–97 as I am, and I assume that most of you here sat in on the discussions that were held at both the special session of the House of Delegates in October and the interim session of the House of Delegates in Philadelphia during the past year. Many resolutions were introduced having the same general tone, advising the medical profession not to participate in the implementation of the so-called Medicare Law, although at these same sessions our legal and ethical rights were outlined by the legal counsel for the American Medical Association.

We were told that the Judicial Council has ruled: "Under ordinary circumstances the individual physician, acting independently, is ethically free to select his patients, although under some circumstances the physician's freedom to select his patients may be circumscribed by overriding ethical considerations." These overriding ethical considerations were listed as follows:

1. A physician should respond to any request for his assistance in an emergency.

2. Once having undertaken a case, the physician should not neglect the patient; nor should he withdraw from the case without giving sufficient notice to allow the patient time to obtain another physician.

3. If a physician decides not to participate in the Medicare program or decides to limit his participation, he should so advise the patient in advance of treatment. This applies to services rendered by the physician both in and out of the hospital and to other services provided under the law.

4. As provided in Section 1 of the Principles of Medical Ethics, a physician should not refuse to render medical care to any person if, as a result, such person will be unable to get necessary medical care.

It was also pointed out that a physician should not render services under terms and conditions which tend to interfere with or impair the free and complete exercise of his medical judgment and skill or which tend to cause a deterioration of medical care.

As of the time this paper was written there were no firm regulations regarding the implementation of the Medicare law published by the Department of Health, Education and Welfare. Whether such regulations would be of such a nature as to prohibit participation by an ethical physician in the program remains to be determined.

During the discussions on non-participation I was able to form my own conclusion, based on the language of the law itself, but not on any regulations which the Department of Health, Education and Welfare might promulgate.

I do not believe it would be ethical for me to refuse hospital care or to refuse to certify an over-65-aged patient as needing hospital care if she desires to make use of the hospital benefits under this law. Actually, this certification does not vary a great deal from that required in certifying the necessity for hospitalization under an insurance program.

Hence, I believe it would be unethical for me to refuse to care for this patient in the hospital under the Medicare plan, provided, of course, that the regulations promulgated make it possible for me to give this patient as good care under the Medicare program as it would be if she were to receive care under any other program of hospitalization.

Under the medical insurance program of P. L. 89–97 I also believe it would be entirely ethical for me to receive compensation for my care of this individual under the law, provided I am ethical in making the charges to this individual. It is my intention, and I believe it is the intention of most of the doctors I have talked to regarding this problem, that the patient will be billed directly for my care, as has been the custom in the past. At the present time I do not believe that I could make up my mind regarding the ethics of taking an assignment from the patient and being paid directly by the carrier under government auspices.

This problem, I believe, will be solved when the final regulations adopted by the Department of Health, Education and Welfare are available for our study.

Under Section 9 of our Code of Ethics it states:

"A physician may not reveal the confidences entrusted to him in the course of medical attendance, or the deficiencies he may observe in the character of patients, unless he is required to do so by law or unless it becomes necessary in order to protect the welfare of the individual or of the community."

This question of confidentiality and/or privilege worries all of us. But this question was clarified a great deal to me in an article written by Julia Pearls, LL.B., in the October 1965 issue of the Journal of the New York State Medical Society. In the first paragraph she writes:

"Confidentiality is the disclosure of information imparted under circumstances which are such that the person giving the confidence relies on the nature of the relationship or on an express promise to insure secrecy. No privilege is accorded such a communication. 'Privilege' is a word of art. It is a right to restrain a communication made in confidence from disclosure to anyone under any circumstance. One might say that confidentiality is an ethical principle; privilege is a legal right."

If the regulations promulgated by the Department of Health, Education and Welfare make it necessary for us to divulge confidences without the patient's consent, this would clearly violate our code of ethics.

In conclusion, there has been much public discussion regarding the need for us to modify or to modernize our Code of Ethics in order to make it relative rather than absolute. We are told that we are out of tune with the times, that we are prisoners of our contemporary principles. It has been stated that a sense of history would remind us of the inevitable obsolescence of most principles, the abandonment of which would permit a more imaginative approach to some of the serious problems now facing us. God forbid!

Webster defines "medical ethics" as "moral principles or the morals of an individual action or practice." My imagination is staggered when I try to conceive of a great society of the future wherein morals and principles are fleeting and ephemeral.

I would like to close with this quotation from Henry Van Dyke:

"Four things a man must learn to do if he would make his record true:

"1. To think without confusion clearly;
"2. To love his fellow men sincerely;
"3. To act from honest motives purely;
"4. To trust in God and heaven securely."

Forgetting of a wrong is mild revenge.

Bamadex® Sequels®

Contraindications: In hyperexcitability and in agitated prepsychotic states. Previous allergic or idiosyncratic reactions.

Precautions: Use with caution in patients hypersensitive to sympathomimetic compounds, who have coronary or cardiovascular disease, or are severely hypertensive.

Dextro-amphetamine sulfate: Use by unstable individuals may result in psychological dependence.

Meprobamate: Careful supervision of dose and amounts prescribed is advised; especially for patients with known propensity for taking excessive quantities of drugs. Excessive and prolonged use in susceptible persons, e.g. alcoholics, former addicts, and other severe psychoneurotics, has been reported to result in dependence. Where excessive dosage has continued for weeks or months, reduce dosage gradually. Sudden withdrawal may precipitate recurrence of pre-existing symptoms such as anxiety, anorexia, or insomnia; or withdrawal reactions such as vomiting, ataxia, tremors, muscle twitching and, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, reduce dose—operation of motor vehicles, machinery or other activity requiring alertness should be avoided. Effects of excessive alcohol consumption may be increased by meprobamate. Appropriate caution is recommended with patients prone to excessive drinking. In patients prone to both petit and grand mal epilepsy meprobamate may precipitate grand mal attacks. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side Effects: Overstimulation of the central nervous system, jitteriness and insomnia or drowsiness.

Dextro-amphetamine sulfate: Insomnia, excitability, and increased motor activity are common and ordinarily mild side effects. Confusion, anxiety, aggressiveness, increased libido, and hallucinations have also been observed, especially in mentally ill patients. Rebound fatigue and depression may follow central stimulation. Other effects may include dry mouth, anorexia, nausea, vomiting, diarrhea, and increased cardiovascular reactivity.

Meprobamate: Drowsiness may occur and can be associated with ataxia, the symptom can usually be controlled by decreasing the dose, or by concomitant administration of central stimulants. Allergic or idiosyncratic reactions: maculopapular rash, acute nonthrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever, transient leukopenia. A case of fatal bullous dermatitis, following administration of meprobamate and prednisolone, has been reported. Hypersensitivity has produced fever, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, stomatitis, proctitis (1 case), anaphylaxis, agranulocytosis and thrombocytopenic purpura, and a fatal instance of aplastic anemia, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity, usually after excessive dosage. Impairment of visual accommodation. Massive overdosage may produce drowsiness, lethargy, stupor, ataxia, coma, shock, vasomotor, and respiratory collapse.

Lippmann, M.D.; 26 Washington Avenue West; Hutchinson.

GENERAL PRACTITIONER WANTED for small town practice with two other general practitioners. Practice to include surgery and obstetrics within your own capabilities. Eligible for partnership after first year. Write: MINNESOTA MEDICINE — 359; 496 Lowry Medical Arts Building, St. Paul 55102.

EASTERN WISCONSIN CLINIC in rapidly growing community of 40,000 desires board-eligible or certified physicians in pediatrics, obstetrics and gynecology and internal medicine. Well-equipped clinic and excellent hospital facilities. Lake shore location offers ample recreational facilities. Attractive financial plan leading to early full partnership. Full expenses paid for applicants invited to interview. Call or write: F. L. Hildebrand, M.D., Riverside Clinic, Menasha, Wisconsin.

DOCTORS OFFICES IN MINNEAPOLIS — formerly occupied by three pediatricians. Includes six examining rooms, large waiting room, laboratory, half bath, parking. Located on bus line close to most hospitals. For further information call or write Mrs. Brooks, Premier Realty, 7325 Wayzata Blvd., 544-4451.

WANTED — INTERNIST, Board certified or qualified to associate with 5-doctor clinic. In growing economy of industrial and Summer and Winter tourist area. Grand Rapids Clinic, Grand Rapids. Telephone 1-218-326-3436.

FOR RENT — Modern, air-conditioned building readily adaptable for a group of doctors or clinic located near 44th and France in highly desirable Edina-Morningside of Minneapolis. Adjacent parking. Contact owner, Ted Shirley, 926-3460.

Cardiac Program for Physicians

The Ramsey County Heart Division of the Minnesota Heart Association, in cooperation with the United States Department of Health, Education and Welfare, is sponsoring an on-going series of cardiac conference programs.

The programs are being held at Charles T. Miller Hospital, 125 West College Avenue, St. Paul, and is open to all physicians free-of-charge.

This clinical conference brings together the departments of medicine, surgery, radiology, anesthesiology, and pathology in considering interesting aspects of cardiac disease.

The conference meets every other Wednesday, alternating with the established Cardiac Pathology conference.

A complimentary buffet luncheon is served at 11:45 a.m. in College Hall at the Charles T. Miller Hospital, and the lectures and conferences are held from 12:30 p.m. to 1:30 p.m., in the College Hall amphitheater.

For more information call the Minnesota Heart Association, 646-6554. Advance reservations are unnecessary.

- *antihistaminic action* relieves sneezing, nasal congestion, pruritus, and lacrimation
- *antispasmodic action* alleviates bronchial and gastrointestinal spasm.

Precautions: Persons who have become drowsy on this or other antihistamine-containing drugs, or whose tolerance is not known, should not drive vehicles or engage in other activities requiring keen response while using this product. Hypnotics, sedatives, or tranquilizers if used with BENADRYL should be prescribed with caution because of possible additive effect. Diphenhydramine has an atropine-like action which should be considered when prescribing BENADRYL.
Side Effects: Side reactions, commonly associated with antihistaminic therapy and generally mild, may affect the nervous, gastrointestinal, and cardiovascular systems. Most frequent reactions are drowsiness, dizziness, dryness of the mouth, nausea, and nervousness. BENADRYL is available in Kapseals® of 50 mg. and Capsules of 25 mg.

Brewer Diagnostic Kits

Complete Serological Screening Tests For Syphilis . . .

The RPR Card Tests make use of a specially prepared, carbon-containing RPR Card antigen. The particle size and other characteristics of the carbon is such that when a reactive specimen is encountered, flocculation occurs, and there is a coagglutination which is readily visible to the naked eye. Individual tests, including the collection of blood and separation of plasma can be performed in 7 to 8 minutes.

Confirming earlier findings with the RPR Card Test[1-10] Reed[11] in reporting on 63,800 specimens had an overall agreement of 98.5% in a recent comparative study with other routine screening procedures.

The RPR Card Tests, with their low cost, ease of performance, high sensitivity and specificity, are without peer in situations that demand rapid testing of patients, enabling the physician to initiate prompt treatment of early infectious syphilis.

Specify the RPR Card Test as the screening procedure on serum or plasma samples submitted to your State Approved Laboratory.

Winthrop announces
new
WinGel®
ANTACID
TABLETS
AND LIQUID

For peptic ulcer, gastric hyperacidity, gastritis

Each WinGel tablet or teaspoon (5 ml.) contains 410 mg. of combined, highly reactive, short polymer, aluminum and magnesium hydroxides **stabilized with hexitol.**

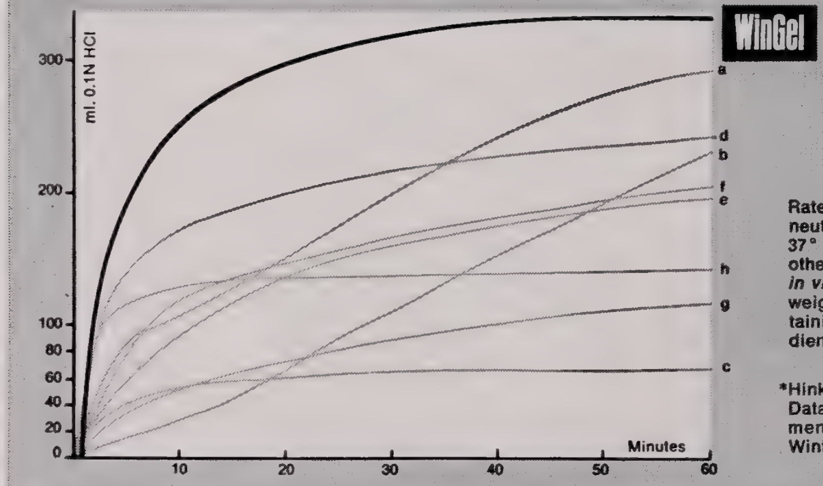
Neutralizes 300 times its active-ingredient weight in gastric acid for fast, long-lasting relief

Gastric or duodenal ulcer, acute or chronic gastritis, gastric hyperacidity...wherever there is "acid overflow" new WinGel can provide faster, longer, more complete neutralization.

In recent laboratory comparisons* with eight other leading antacids, new WinGel tablets not only neutralized more hydrochloric acid per active-ingredient weight, but neutralized it faster and longer than all other antacids tested.

Pleasant pink in color, WinGel is delicately mint flavored with a smooth-as-cream texture—qualities sure to please the patient on long-term therapy. New WinGel is also specially formulated to avoid constipation or diarrhea.

New WinGel neutralizes 300 times its active-ingredient weight in 0.1N hydrochloric acid—neutralizes more acid faster than other leading antacids



Rate of 0.1N hydrochloric acid neutralization at pH 3.5 and 37° with WinGel and eight other leading antacid tablets—*in vitro*. Samples equaled the weight of tablet material containing 1.0 Gm. active ingredients.*

*Hinkel, E. T., Jr. (New York): Data in the files of the Department of Medical Research, Winthrop Laboratories.

Dosage: Peptic ulcer or gastritis—from 2 to 4 teaspoons of WinGel liquid or 2 to 4 tablets chewed or allowed to dissolve in the mouth every two to four hours. **Gastric hyperacidity**—2 tablets or teaspoons about ½ to one hour after meals as needed; children from 7 to 14 years of age, 1 or 2 tablets or 1 or 2 teaspoons of liquid as needed.

How Supplied: Liquid in bottles of 8 fl. oz. and 1 pint. **Tablets** in cellophane strips, boxes of 50 and 100. (One teaspoon of WinGel liquid is equivalent to one WinGel tablet in acid-combining capacity.) WinGel, trademark reg. U.S. Pat. Off.

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Anatomy of
Low Back Pain #1
the sedentary life
is often the seat of
low back pain

The human spine is not engineered f prolonged sitting at desks, pianos, typ writers and drafting boards. The stress set up by the heavy, forward-tilted hea and trunk, balanced precariously on a insufficient base, result in strain of th dorsal musculature, particularly at th low lumbar level.

The unusual muscle-relaxant and ana gesic properties of 'Soma' make it esp cially useful in the treatment of low bac sprains and strains. 'Soma' is wide prescribed ☐ **to relieve pain** ☐ **to rel muscles** ☐ **to restore mobility.**

Indications: 'Soma' is useful for management muscle spasm, pain, and stiffness in a variety inflammatory, traumatic, and degenerative musc loskeletal conditions. It also may act to normali motor activity in certain neurologic disturbance

Contraindications: Allergic or idiosyncratic rea tions to carisoprodol.

Precautions: 'Soma', like other central nervo system depressants, should be used with cautio in patients with known propensity for taking e cessive quantities of drugs and in patients wi known sensitivity to compounds of similar chem cal structure, e.g., meprobamate.

Side Effects: The only side effect reported with a frequency is sleepiness, usually on higher tha recommended doses. An occasional patient m not tolerate carisoprodol because of an individu reaction, such as a sensation of weakness. Oth rarely observed reactions have included dizzines ataxia, tremor, agitation, irritability, headache, i crease in eosinophil count, flushing of face, ar gastrointestinal symptoms.

One instance each of pancytopenia and leuk penia, occurring when carisoprodol was admi istered with other drugs, has been reported, as h an instance of fixed drug eruption with carisoprod and subsequent cross reaction to meprobamat Rare allergic reactions, usually mild, have include one case each of anaphylactoid reaction with mi shock and angioneurotic edema with respirato difficulty, both reversed with appropriate therap In cases of allergic or hypersensitivity reaction carisoprodol should be discontinued and approp ate therapy initiated. Suicidal attempts may pr duce coma and/or mild shock and respirato depression.

Dosage: Usual adult dose is one 350 mg. tabl three times daily and at bedtime.

Supplied: Two Strengths: 350 mg. white table and 250 mg. orange, two-piece capsules.

Before prescribing, consult package circular.

for the relief of low back sprains and strain

President's Letter

FOR THOSE doctors uncertain of their coronary competence but unwilling to take any of the standard tests, a simple armchair trial is readily available.

Reading, and re-reading with a growing sense of incredulity leading to outrage, the series of articles in the NEW YORKER during late June and July, titled "Annuals of Legislation," subtitled "Medicare," and concluding with a further subtitle, "IV, A Sacred Trust," is a stress situation far more demanding than snow shoveling and grass cutting.

Follow this with a reading of Intermediary Letter #90 from the Bureau of Health Insurance, Department of Health Education and Welfare, "Application of Criteria for Determination of Reasonable Charges."

Conclude, if you can, with the MEDICAL TRIBUNE of July 25, 1966, which carries an interview with Dr. George A. Silver, Deputy Assistant Secretary of Health, Education and Welfare. If you complete these, you may be temporarily an emotional wreck, but your coronaries are functioning well.

The New Yorker series written by Richard Harris is a cynical, distorted attack on the motives behind Medicine's resistance to the passage of Medicare and the bills which preceded it, a more cynical reporting of the political motivations of the supporters of the bill, and an obvious joining by Mr. Harris of the parade of those who attempt to discredit medicine before the public by personal attacks on the sincerity, standards and ethics of medicine's elected leaders and chosen spokesmen. As character assassination, it quite fittingly follows Truman Capote's series on actual assassination, "In Cold Blood," which series ran some weeks earlier.

Most physicians have had experience with Blue Shield and other insurers offering contracts with usual and customary payment for physician services; no difficulties have arisen in these areas. To date, no criteria, no regulations, no sampling, nothing but physician integrity has been required for successful operation. To date nothing but an occasional request for physician-committee decision in unusual cases has been needed to continue that successful operation. No recognition of physician integrity is present in the Bureau of Health Insurance memorandum, nor recognition of physician-developed mechanisms of control. Equally odd, tacit acknowledgement of the quality of medical service appears to be present without question, memorandum or guidelines.

To have Dr. Silver propose in his interview that "if medical students could be channeled to the career goals where the need is greatest" some of our needs could be met in physician placement is regimentation of another type, compatible with centralized planning, acceptable in a Welfare State, and possibly an indication of future governmental involvement in education.

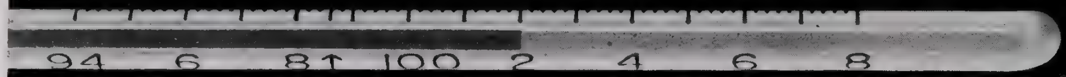
Mr. Harris, ending his series with a quotation from Senator Douglas, finishes "The Doctors of this country say they have a Sacred Trust, I hope they keep it."

How much we as physicians would appreciate the same assurance and performance from these sources.

R P Buckley M.D.

R. P. Buckley, M.D.
President
Minnesota State Medical Association

good reason
to select
Ilosone®
Erythromycin Estolate
for bacterial
infections



two to four times
the therapeutic
activity of other
erythromycins

CONTRAINDICATIONS: Ilosone is contraindicated in patients with a known history of sensitivity to this drug and in those with preexisting liver disease or dysfunction.

SIDE-EFFECTS: Even though Ilosone is the most active oral form of erythromycin, the incidence of side-effects is low. Infrequent cases of drug idiosyncrasy, manifested by a form of intrahepatic cholestatic jaundice, have been reported. There have been no known fatal or definite residual effects. Gastro-intestinal disturbances not associated with hepatic effects are observed in a small proportion of patients as a result of a local stimulating action of Ilosone on the alimentary tract. Although allergic manifestations are uncommon with the use of erythromycin, there have been occasional reports of urticaria, skin eruptions, and, on rare occasions, anaphylaxis.

DOSAGE: *Children under 25 pounds*—5 mg. per pound of body weight every six hours. *Children 25 to 50 pounds*—125 mg. every six hours. *Adults and children over 50 pounds*—250 mg. every six hours. For severe infections, these dosages may be doubled.

Available in Pulvules®, suspension, drops, and chewable tablets. Ilosone Chewable tablets should be chewed or crushed and swallowed with water.

Additional information available to physicians upon request.

The Anovulatory Syndrome

Treatment with Clomiphene*

W. N. SPELLACY, M.D.**
W. D. COHEN, Ph.D.**
Minneapolis, Minnesota

THE GYNECOLOGIST today is frequently asked to treat the "anovulatory syndrome." This syndrome may present itself in many ways: infertility, amenorrhea, or irregular uterine bleeding. The treatment of this syndrome first requires a specific etiological diagnosis to be made. Since the possible factors which can inhibit ovulation are numerous, one must begin with a complete history and physical examination, including also a complete endocrine evaluation. A large subgroup of patients discovered by this type of study are those with deficient pituitary gonadotropin secretion.

The treatment of patients with low pituitary gonadotropin secretion has gone through four stages of development. The first period covered the years before 1950 when nonspecific treatments were employed, such as estrogen, thyroid, or sedation. Since the treatment was nonspecific, it could not be expected to be very successful and it was not.

The second period occurred in the early 1950s when it was shown that X-ray irradiation of the pituitary gland and the ovary would restore their function in a significant number of patients.[2,3] The mechanism of action was unknown but possibly the increased vascularization following irradiation increased gland function. The suggestion that possible genetic damage could be produced in the patients and transmitted to their progeny discredited this form of therapy. It is rarely used today.

The third period began in the late 1950s and involved the use of exogenous gonadotropin injection with a luteinizing hormone preparation which was readily available in the form of human chorionic gonadotropin. However, a follicle-stimulating hormone was not so easily secured; the first supplies of it were from non-human sources. The problems incurred with these preparations were the production of antibodies to the foreign protein antigen and the lack of patient response due to the species-specific reaction of some hormones.[3] Gemzell and others have subsequently obtained human follicle-stimulating hormone for use and have found it to be effective.[4] The problems involved in its use, however, have been the difficulty and expense of obtaining the hormone, the need for daily injections, and the problem of individualizing dosages.

---

*Clomiphene was supplied by the William S. Merrell Company, Cincinnati, Ohio, as Clomid®.

See editorial page 1399.

**From the Department of Obstetrics and Gynecology, University of Minnesota Medical School, Minneapolis, Minnesota.

The fourth period began in 1961, when Greenblatt reported the successful induction of ovulation with Clomiphene.[5] This compound is a nonsteroid, nonhormonal agent which can be clinically synthesized and administered orally.

The purpose of this paper is to present one typical case report of a patient successfully treated with Clomiphene, and to review the action and uses of this drug.

Case Report

A 29-year-old para 1-0-0-1 white female had delivered a normal infant in June 1961. She had not had a menstrual period since that time (33 months) but had had normal menstrual periods prior to that pregnancy. She was seen at the University of Minnesota Hospitals with a complaint of secondary infertility and amenorrhea. The remainder of her history and the physical examination were normal. The laboratory studies included a normal complete blood count, urinalysis, chest x-ray, serology, fasting blood sugar, and serum electrolytes. From the endocrine studies shown on Table 1 it can be seen that all of her endocrine target gland secretions are low. There was no response to the standard Metopirone* pituitary function test (30 mgm/kg. body weight; 4-hour intravenous infusion). A diagnosis of idiopathic hypopituitarism was made and she was treated with Clomiphene. The first three treatment cycles were monitored with basal body temperatures, and on this basis the patient ovulated in each cycle and became pregnant during the third cycle. She had a normal pregnancy and on 10/6/65 spontaneously delivered a 2980-gram normal female infant over an episiotomy using pudendal block anesthesia. She has not menstruated post partum.

Discussion

The action of Clomiphene has been found to be different in experimental animals and in humans. Several investigators have shown the compound to be antiestrogenic and therefore an inhibitor of ovulation in animals.[6] It has also been shown to be toxic to the blastocyst in early pregnancy, thus preventing implantation.[7]

The action of the drug has been extensively studied in humans. There is no direct action on the adrenal gland.[8] The drug is antiestrogenic and produces a decrease in vaginal cornification count and a loss of cervical mucus spinnbarkeit and fern pattern.[9]

The studies of gonadotropin excretion show a rise in luteinizing hormone, follicle-stimulating hormone, and total gonadotropins after treatment.[10] This occurs in both men and women. We now know that the anterior pituitary gland is under the direct control of the hypothalamus which secretes specific polypeptide releasing factors. The hypothalamus in turn is responsive to circulatory estrogen levels, thus closing a negative-feedback loop. Presumably, Clomiphene acts by causing the hypothalamus to secrete gonadotropin-releasing factors which then enter the anterior pituitary gland via the pituitary portal circulation. If there is a normal pituitary, gonadotropin is released into the general circulation, and if normal ovaries are present, they will respond with ovulation.[11]

TABLE I
Endocrine Studies Prior to Clomiphene Treatment

Pituitary		
Sella turcica x-ray — normal		
Follicle stimulating hormone — less than 4 mouse units/24 hours (normal 6-48)		
Thyroid		
Protein bound iodine — 4.0 μgm. % (normal 4-8)		
Cholesterol — 207 mgm. %		
Ovary		
Cornification count — 3% superficial cells		
Endometrial biopsy — inactive proliferative phase		
Adrenal		
Control 24 hour urinary excretion		
17 ketosteroid	6.6 mgm. q.d. (normal 5-15)	
17 hydroxycorticoids	2.4 mgm. q.d. (normal 4-12)	
Plasma Corticoids		
8 a.m.	17.2 μgm. % (normal 5-35)	
8 p.m.	12.4 μgm. %	
ACTH Test (50 units — 8 hours)		
	Pre	Post
17 ketosteroids	5.3	9.6 mgm. q.d.
17 hydroxycorticoid	3.3	25.7 mgm. q.d.
Plasma corticoid	21.6	42.9 μgm. %
Metopirone Test		
	Pre	Post
17 hydroxycorticoids	4.1	3.9 mgm. q.d.

---

*Metopirone was supplied by Ciba Pharmaceuticals Company, Summit, New Jersey.

Clomiphene has been used for the treatment of many conditions, including irregular menses, endometrial hyperplasia, amenorrhea, infertility, precocious puberty, Stein-Leventhal syndrome, carcinoma of the endometrium, cystic mastitis, galactorrhea, and oligospermia.[11]

The success in producing ovulation has been approximately 70% in those patients who have an intact pituitary gland and ovary. The pregnancy rate is approximately 23%.[12]

The side effects incurred by using this drug are dose-related. Few of them are serious. They include hot flashes, blurry vision, ovarian cyst formation, nausea and vomiting, vertigo, mittelschmerz, and alopecia.[11]

The drug is given orally and the usual dosage is 50 mgm. twice each day for five days every month. Patients should be examined between each treatment period.

Conclusion

With Clomiphene, the gynecologic endocrinologist has a new effective therapeutic tool with which to treat the "anovulatory syndrome."

Acknowledgment

The authors wish to express their appreciation to Dr. John E. Johnson, Jr., of the William S. Merrell Company for his generous supply of Clomid.

IT'S THE LAW*

Physicians, surgeons, nurses, pharmacists and hospital officials are required to notify police whenever they come upon injuries that appear to have arisen from mistreatment of youngsters under 16 years of age. This will better identify children in danger so that they may be protected. The law is not to punish parents although criminal action may result in some instances. Such reporting is mandatory and allows the protective services throughout the State to be brought to bear in an effort to protect the health and walfare of these children and to prevent further abuses.**

Above all things, keep clean; it is not necessary to be a pig in order to raise one.

— Robert Ingersoll

Efficaciousness in Proportion to Cost

About a generation ago, it was suggested by some of the pharmacologists that certain of the salts of lithium, especially when taken in the diluted form in which they occurred in natural waters and medicinal springs, were of very great value for the cure and prevention of the formation of calculi in the human body.

The lithium and lithia springs throughout the country followed up this popular persuasion of curative value with properly suggestive advertising, and lithium waters were consumed by the hundreds of thousands of gallons every year. Then the government became interested in the question of pure food and drugs and made a careful analysis of these so-called natural lithium waters. It was found that so far as some of the most famous of them were concerned there was more lithium in the Potomac as it flowed by Washington than there was in the much advertised and much consumed natural lithium water. It was found further that the Potomac was not particularly rich in lithium and that it would probably take some thousands of gallons, at least, of Potomac water to provide what would ordinarily be considered a single reasonable therapeutic dose of lithium.

The one really efficacious factor in this lithium water was not the lithium but the water. . . . Those who were relieved in any way, however, were quite sure it was the lithium that was effecting its beneficent work. . . . Water is too cheap to cure most people. The rich man at Rome complained to Galen that he could not be cured by these drugs that were so cheap that even the poor could obtain them to cure themselves and he must have something more expensive for that purpose, for surely the remedy would be more efficacious just in proportion to the increased amount of money that he had to pay for it.*

Mechanical Large Bowel Obstruction

Simulating Paralytic Ileus

CLAUDE V. DESHAZO, M.D.*
CHARLES A. MURRAY, M.D.*
RAYMOND C. BONNABEAU, JR., M.D.*
Minneapolis, Minnesota

THE USE OF routine x-ray studies of the abdomen has been invaluable in permitting the early diagnosis of both small and large bowel obstruction when the clinical findings are equivocal. The following communication concerns two cases of mechanical large-bowel obstruction in which three competent radiologists and the responsible physicians were led to a diagnosis of paralytic ileus by the clinical picture and the radiologic findings.

Case Reports

Case 1:

A 36-year-old woman was admitted to the surgical service because of unrelenting abdominal distention of four days' duration. The patient, who was unable to give any history, had had no prior abdominal operations and had received several enemas before referral in an effort to reduce this distention. Vital signs were normal while physical examination revealed only moderate abdominal distention and the absence of bowel sounds. Digital rectal examination and routine laboratory studies were normal.

Radiographic studies of the abdomen were interpreted as showing a large amount of gas in the colon with some in the small bowel (Figure 1-a). The fluid levels seen in the colon in the upright film (Figure 1-b) were felt to be due to the multiple enemas the patient had received previously. The films were considered to be compatible with a paralytic ileus.

Proctoscopy to 25 cm. revealed no lesions. No gas or fluid was expelled during the examination. An emergency barium enema (Figure 1-c) revealed a caecal volvulus. Exploratory laparotomy confirmed the diagnosis.

Case 2:

A 63-year-old woman was admitted to the surgical service because of a symptomatic hiatus hernia. Physical examination was unremarkable, and on the eighth hospital day a vagotomy, pyloroplasty, and hiatus herniorrhaphy were performed. On the seventeenth postoperative day the patient was noted to have abdominal distention with an absence of bowel sounds.

On the basis of the physical findings and a dilated colon on the abdominal x-rays (Figure 2-a) a diagnosis of paralytic ileus was made. The abdominal distention did not relent with nasogastric suction and a sigmoidoscopy revealed no lesions and yielded no gas or fluid. A barium enema demonstrated obstruction at the splenic flexure of the colon (Figure 2-b), which subsequently was found at operation to be due to an adhesive band.

---

*Department of Surgery, University of Minnesota Hospitals, Minneapolis, Minnesota.

Comment

These two cases represent instances in which the establishment of a diagnosis of mechanical large bowel obstruction was delayed because the radiographic picture was interpreted as being consistent with paralytic ileus. Both patients failed to present the classical physical findings and symptoms of mechanical obstruction, namely, hyperactive bowel sounds, rushes, and cramping abdominal pain.

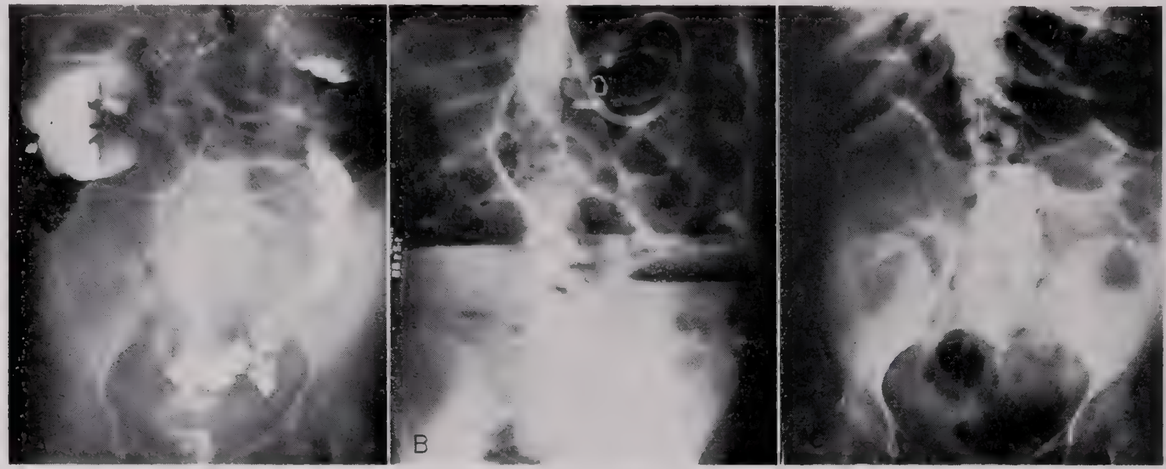

Fig. 1 — This 36-year-old woman (Case 1) was admitted to the hospital with a four-day history of abdominal distress. (a-left) A photograph demonstrating a caecal volvulus in the right upper quadrant as seen on barium enema and confirmed at the time of surgery. (b-middle) A photograph of an upright film of the abdomen illustrating fluid levels in the colon attributed to multiple enemas the patient had received prior to admission. (c-right) A photograph of the initial flat plate of the abdomen showing distended loops of the large and small bowel.

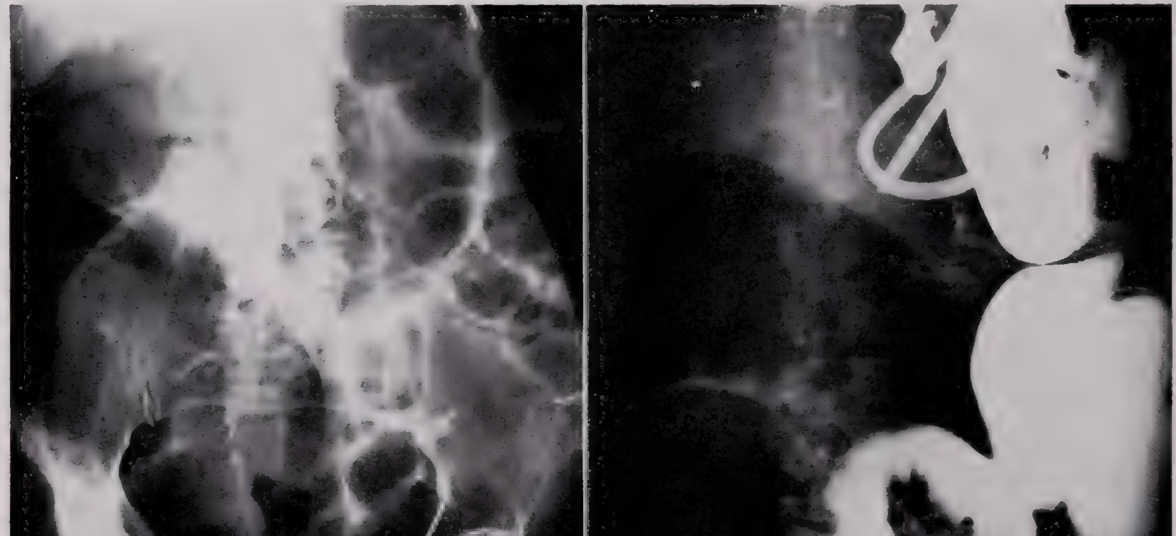

Fig. 2 — (a-left) A photograph of the abdominal x-ray in Case 2 taken on the seventeenth postoperative day after a vagotomy, pyloroplasty and hiatus herniorrhaphy were performed. The film shows distended loops of colon without fluid levels. (b-right) A photograph demonstrating the site of obstruction at the splenic flexure of the colon found by barium enema. This obstruction was found to be due to an adhesive band at the time of re-operation.

The radiographic differentiation between mechanical and paralytic ileus is characteristically based not only on the presence of air-fluid levels, but also on the absence of air distal to the point of obstruction. In both of the cases presented these clear-cut radiographic manifestations were missing. In Case 1 the utilization of enemas prior to the radiographic examination further confused the issue due to the introduction of air and fluid into the large bowel.

In cases of unrelenting bowel distention where the colon is distended but x-ray findings are equivocal or even give the appearance of paralytic ileus, the use of sigmoidoscopy and barium enema is of extreme importance. If facilities for barium enema are not available initially, sigmoidoscopy will generally reveal normal colon and no gas or fluid in the distal bowel if there is a mechanical obstruction. Barium enema can then be obtained to delineate the obstructed area in the colon.

Summary

Flat and upright radiographic studies of the abdomen are a valuable diagnostic tool and are used extensively to differentiate between paralytic and mechanical ileus. The early use of both sigmoidoscopy and barium enema in these two cases was necessary to establish a diagnosis. In cases of unrelenting abdominal distention due to mechanical large-bowel obstruction, where the radiographic picture appears compatible with a paralytic ileus, the use of these procedures may be lifesaving.

Medical Men and Music

Apollo and Aesculapius

Music exalts each Joy, allays each Grief,
Expells Diseases, softens every Pain,
Subdues the rage of Poison, and the Plague;
And hence the wise of ancient days adored
One power of Physic, Melody, and Song.

In the Greek and Roman pantheon Apollo, god of music and healing, and his son and pupil Aesculapius, god of medicine, were jointly venerated as divine practitioners of sister arts. In the iatro-philosophy of the ancients disease was the result of spiritual and, by extension, physical disharmony with the grand systole and diastole of Nature. Restoration of health therefore required the resynchronization of the vibration of the human soul with that of the anima mundi.* Hence the iatromantic therapy of the Greeks and Romans — employing music as a reciprocal psycho-iatric and physico-iatric agent.

Sometimes music was used in conjunction with other prophylactic measures. Pythagoras' psychobiosis featured a combination of music and diet; and Homer recounts that when Ulysses hemorrhaged from a wild boar gash, attendants first bandaged the wound and then chanted a song of healing thereon.

But generally music alone sufficed. Cato relied on ancient songs to heal sprains and Varro to relieve gout. Herophilus of Alexandria was reported to have successfully treated disease by regulating his patients' pulses according to the particular musical scale he considered most appropriate in each individual case. Especially responsive to the melodious tones of the flute were ischialgia, lumbago, snakebite, and insanity.

And after all did not Saul's profound melancholia vanish at the sound of David's harp?

Mikulicz' Syndrome

This syndrome consists of bilateral painless enlargement of the salivary and lacrimal glands, accompanied by dryness of the mouth and decreased or absent lacrimation. Mikulicz first described the condition in 1892. Schaffer and Jacobsen in 1927 reviewed the subject comprehensively and offered an etiologic classification.

The localized glandular enlargement is usually a manifestation of a generalized disease process. In most cases the causative factor has been found to be either tuberculosis, leukemia, lymphosarcoma, or sarcoidosis. In one group reported by Radding, 24 out of 38 cases were associated with leukemia. Diagnosis may often be facilitated by study of the bone marrow.

Rubin and Besse have suggested a differentiation between the terms "Mikulicz' syndrome" and "Mikulicz' disease." They state that in the syndrome roentgenographic studies of the parotid gland show a normal branching duct system with complete evacuation of contrast medium during the emptying phase, whereas in Mikulicz' disease there is sialectasis or dilatation of the terminal ducts that may become cystic. The course is variable, usually chronic, and recurrences are frequent. Treatment depends upon the etiologic factors. If a blood dyscrasia exists, specific measures should be used. Surgical excision and irradiation of the salivary glands have been done. If biopsy supports the diagnosis of sarcoidosis, hydrocortisone therapy may yield favorable results.

Oliver Wendell Holmes on Know-How

Book-knowledge, lecture-knowledge, examination-knowledge, are all in the brain. But work-knowledge is not only in the brain, it is in the senses, in the muscles, in the ganglia of the sympathetic nerves,—all over the man, as one may say. . . . See a skillful surgeon handle a broken limb; see a wise old physician smile away a case that looks to the novice as if the sexton would soon be sent for; mark what a large experience has done for those who were fitted to profit by it, and you will feel convinced that, much as you know, something is still left for you to learn.

The Mona Lisa

Hers is the head upon which all the ends of the world are come, and the eyelids are a little weary. It is a beauty wrought out from within upon the flesh, the deposit, little cell by little cell, of strange thoughts and fantastic reveries and exquisite passions. . . . All the thoughts and experience of the world have etched and moulded there, in that which they have of power to refine and make expressive the outward form, the animalism of Greece, the lust of Rome, the mysticism of the middle age with its spiritual ambition and imaginative loves, the return of the Pagan world, the sins of the Borgias. She is older than the rocks among which she sits; like the vampire, she has been dead many times, and learned the secrets of the grave; and has been a diver in deep seas, and keeps their fallen day about her; and trafficked for strange webs with Eastern merchants; and as Leda, was the mother of Helen of Troy, and, as Saint Anne, the mother of Mary; and all this has been to her but as the sound of lyres and flutes, and lives only in the delicacy with which it has moulded the changing lineaments, and tinged the eyelids and the hands.—Walter Pater

Gangrene of the Foot Following Operation

Lumbar Sympathectomy*

M. J. LOEB, M.D.**
Y. SAKO, M.D.**
Minneapolis, Minnesota

TRULY DRAMATIC improvement in circulation in patients with arterial occlusive disease is obtainable by direct arterial reconstructive surgery, but the limiting factor has been that only 15 to 20% of patients with femoropopliteal occlusive disease are suitable candidates for reconstructive operations. For the remaining large group of patients the only surgical consideration is that of lumbar sympathectomy as an adjunct to medical management.

Lumbar Sympathectomy

Lumbar sympathectomy for ischemia of the extremities has been performed for forty years, and it is common knowledge that skin circulation is markedly improved in those that respond favorably to sympathectic denervation; whereas improvement in circulation to the muscles is not to be expected. Nevertheless, nearly every reported series of lumbar sympathectomy will record 20 to 30% of the patients as having increased walking distance postoperatively.

Variable Response

Individual response to lumbar sympathectomy varies; at one time detailed studies were performed in an attempt to select those that might respond favorably. Experience has shown that preoperative tests could not be relied upon for accurate prediction; therefore our tendency has been to recommend lumbar sympathectomy to all patients except those with advanced disease such as gangrene no longer limited to the digits or in patients with overall general poor health. Liberal indications for recommending lumbar sympathectomy have also been prompted by the desire to offer the patient the potential benefit of improvement or limb salvage. Also, the mortality attending the operation has been low — less than 1% in over 400

---

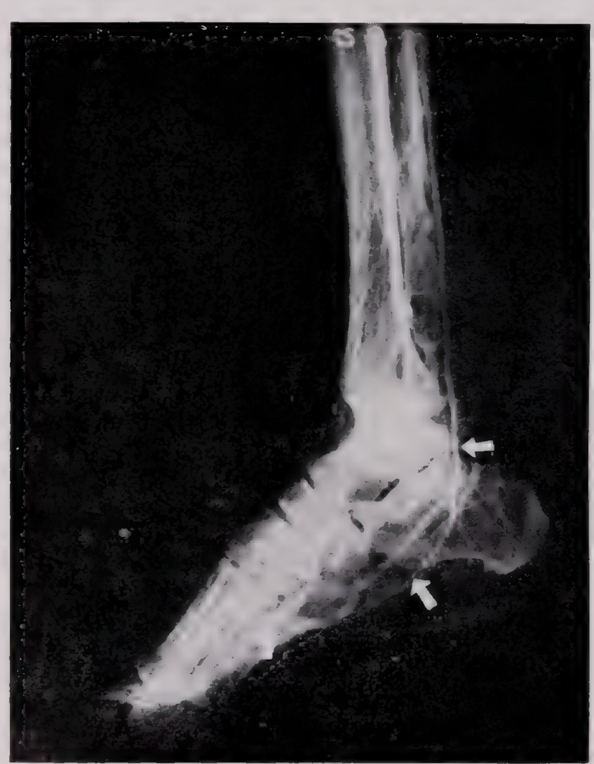

Fig. 2 — Angiographic study of amputated specimen showing patent posterior tibial artery (arrows).

lumbar sympathectomies over a ten-year period.

Low-Risk Complications

The commonest postoperative complaint is that of postsympathectomy neuralgia, which occurs in 20 to 25% of patients. Other than the neuralgia being secondary to the procedure of sympathectomy, the etiology is somewhat obscure. Fortunately, the difficulty is self-limited to about six weeks. Another complication is that of disturbance in male sex function if bilateral lumbar sympathectomy includes the first lumbar segment. This complication can be avoided by not disturbing the first lumbar ganglion on one side.

Paradoxical Response

Another complication of lumbar sympathectomy, which is quite infrequent but rather striking when it does occur, is that of aggravation of the ischemic symptoms and findings shortly after sympathectic denervation. This has been called a "paradoxical" response. Atlas[1] in 1942 was the first to call attention to this phenomenon; he reported on three patients who had onset of pedal gangrene shortly after lumbar sympathectomy. Baffes et al.[2] also describe three cases felt to represent a "paradoxical" response to sympathectomy. Other investigators[3] have discussed clinical situations where this is likely to occur.

Case Report

A 67-year-old mildly diabetic man being treated for congestive failure and pneumonia was seen in consultation because of severe ischemia of the right foot. Examination revealed an ulcer 2 x 3 cm. on the large toe. The foot showed no edema. Femoral and popliteal pulses were strong bilaterally but there was no pedal pulse. Treatment consisted of continued bed rest and foot soaks; but after four weeks with no improvement a right lumbar sympathectomy removing ganglions L_2 to L_4 and an amputation of the toe at the metatarsal-phalangeal joint were done. Postoperatively the right upper leg became warmer. Both femoral and popliteal pulses were present and of the same quality as before surgery, but there was rapid progression of the gangrene beginning at the amputation site and spreading proximally to involve the distal medial aspect of the foot (Figure 1). Because healing appeared extremely remote, an amputation was done below the knee. The latter site was chosen because the patient continued to have a strong popliteal pulse, although at the site of amputation the artery was blocked. The amputation site healed primarily.

An angiographic study was made of the amputated limb. This showed occlusion of the anterior tibial and peroneal arteries, whereas the posterior tibial artery was open (Figure 2). The distribution of this artery includes part of the gangrenous area of the foot. The arteries in the area of the gangrene appeared patent (Figure 3).

Discussion

Since there was no apparent progression of the gangrenous changes before sympathectomy, the rapid spread of the necrosis after operation was quite striking and it appeared that there was some causal relationship. Sympathetic denervation of the right leg was apparent because the right thigh and upper lower leg were warmer than preoperatively and the right side was warmer than the left. These observations suggest that acceleration of gangrene was precipitated by shunting of blood from areas distal to the arterial obstruction.

Pressures and flow measurements after lumbar sympathectomy have been made and previously reported.[4] Lumbar sympathectomy provoked an increase in blood flow in the artery proximal to the obstruction; thus in femoropopliteal occlusion flow in the common femoral artery increases following lumbar sympathectomy. There was, however, a fall in pressure in the arterial bed distal to the point of obstruction (Figures 4 and 5). As illustrated in Figure 5, the common femoral artery pressure is 168/104 and the popliteal artery pressure, 68/60. Ten minutes after denervation popliteal artery pressure fell to 36/32. All pressures were direct arterial measurements. This suggests that although lumbar sympathectomy increases the total blood flow to the affect limb, certain areas may actually have a lower tissue perfusion pressure, which may explain the aggravation of the ischemia. With fall in pressure and consequent stasis, arterial occlusion may occur. The fall in pressure undoubtedly is temporary and may actually provoke increase in collateral blood vessel formation, because such vessels tend to form between areas of greater gradient. This may explain why benefits from lumbar sympathectomy occur gradually over a period of up to one year. Although it is difficult to select those

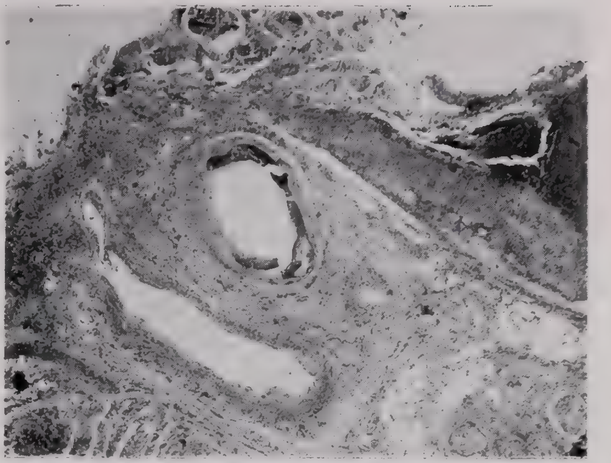

Fig. 3 — Histologic section (x12) taken at level of ulcer showing patent vessels with surrounding gangrenous changes.

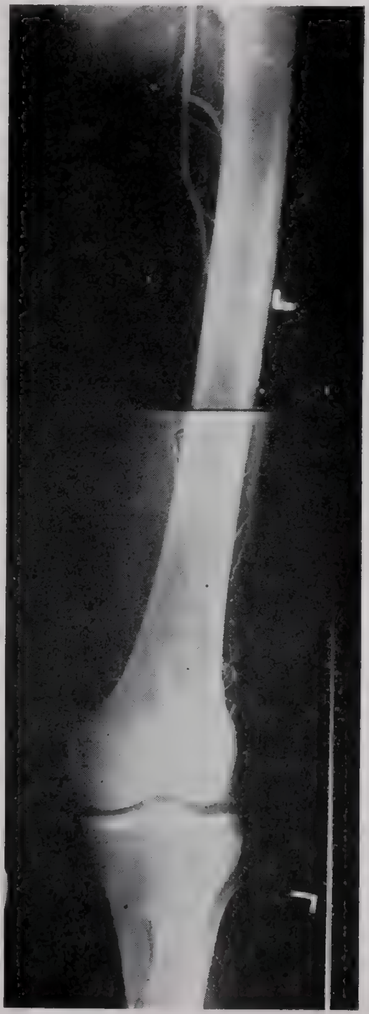

Fig. 4 — 60-year-old male with intermittent claudication. Angiogram shows femoropopliteal artery occlusion. Sympathectomy increased blood flow in the common femoral artery from 140 to 300 cc. mean flow per minute 10 minutes after the nerve section.

patients who may respond adversely, it would appear that those with severe ischemia may be the ones to have aggravation of the ischemia since they could not tolerate a temporary fall in pressure in the area distal to the obstruction.

Summary

A discussion has been presented of a patient who appears to represent an example of a paradoxical response following lumbar sympathectomy. In previous studies, pressure measurements following lumbar sympathectomy suggest that hemodynamic changes may account for aggravation of ischemia following operation. If the immediate effect is not detrimental, it would appear that the fall in pressure would stimulate collateral blood vessel formation.

Since the occurrence of the so-called paradoxical response is infrequent, withholding operation on this basis alone would deprive a great number of patients of the potential benefits from lumbar sympathectomy. At the same time, in patients with advanced disease this hazard ought to be kept in mind.

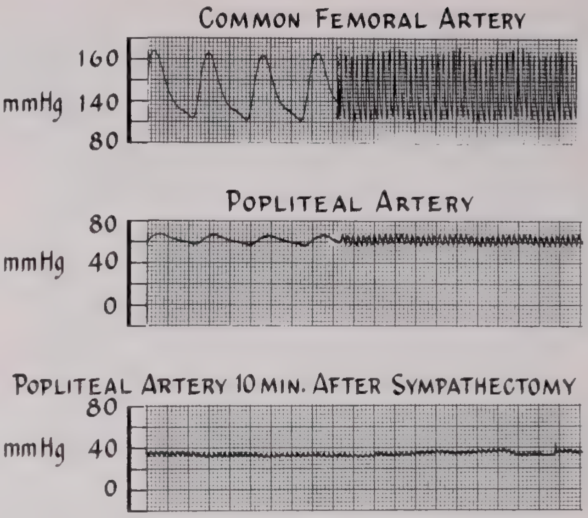

Fig. 5 — Direct arterial pressures in patient described in Figure 4. There was a 53% fall in popliteal artery pressure ten minutes after lumbar sympathectomy.

Mitral Stenosis*

Functional and Clinical Manifestations

JAMES N. KARNEGIS, M.D.**
YANG WANG, M.D.†
St. Paul, Minnesota

THE PURPOSE of this paper is to relate the functional and clinical manifestations of mitral stenosis to the underlying anatomic and pathologic states.

Basic Considerations

Mitral stenosis is a form of obstruction to pulmonary venous outflow. Impairment of pulmonary venous outflow can also occur at other levels, either upstream or downstream to the mitral valve, and mitral stenosis shares hemodynamic findings with these other obstructive conditions.

The fundamental disturbance in mitral stenosis is an impediment to the forward flow of blood. The resultant effect of this abnormality can best be related to the degree of the stenosis, that is, to the area of the mitral valve orifice. The normal mitral valve has an orifice of about five square centimeters. It is generally agreed that this area must be reduced to about twenty per cent of normal or one square centimeter before significant benefit can result from surgical alleviation of the stenosis. It is obviously important not only to diagnose the presence of mitral stenosis but also to determine the severity of the obstruction.

The area of a stenotic mitral valve can be translated into functional equivalents. This requires consideration of the magnitude of the flow of blood through the mitral valve and the pressure gradient producing that flow. The interaction of these three variables can be appreciated from the statement that the amount of flow through the mitral valve in diastole is proportional both to the pressure gradient across the valve and to the valve orifice area. Gorlin and Gorlin[1] have indicated this interrelationship in a useful equation:

$$MVA = MVF/31\sqrt{Pa-Pd}$$

where MVA = mitral valve area
MVF = mitral valve flow
Pa = mean left atrial pressure
Pd = left ventricular mean diastolic pressure
31 = a constant.

From this equation one can see the hemodynamic consequences of mitral stenosis. If the MVA is reduced, a greater pressure gradient is required to maintain the same cardiac output. If the pressure gradient does not increase, the cardiac output must decrease as the severity of the stenosis increases. The severity of mitral stenosis cannot be interpreted from pressure studies alone in patients with congestive heart failure, since the pressure gradient may not be impressive in the face of a low MVF. It is therefore clear that the physiologic assessment of mitral stenosis requires not only knowledge of the pressure gradient but also a simultaneous measurement of the flow through the valve.

In the formula of Gorlin and Gorlin the pressure gradient factor is expressed as a square root, which means that a given change in either the MVA or the MVF alone produces an effect in the pressure gradient of a magnitude related to the square of that change.

Physical Examination

Some patients with mitral stenosis have a peculiar facial coloring. This is especially seen in the cheeks as a dusky-reddish malar flush. Those with a low cardiac output may show cyanosis due to peripheral blood oxygen desaturation. In the presence of pulmonary emboli and pulmonary infarction jaundice may supervene, especially if hepatic congestion coexists.

Cardiac Size

The over-all cardiac size may not be increased in pure mitral stenosis, but palpation will usually reveal a left parasternal heave indicating right ventricular hypertrophy. One may also be able to palpate an opening snap and an apical diastolic thrill.

First Heart Sound[2]

The first heart sound is associated with closure of the mitral valve. With stenosis of the mitral valve there is a tendency for the amplitude of the first heart sound to be increased and for the onset of the sound to be delayed in relation to the beginning of the simultaneously recorded QRS complex of the electrocardiogram.[3]

The delay in the onset of the first heart sound can be explained by the presence of an elevated left atrial pressure. A longer period of time is required during systole for the left ventricular pressure to rise to equal and exceed the high left atrial pressure and thus to close the valve. The elevated left atrial pressure together with the fibrous and other physical changes in the mitral valve resulting from the rheumatic disease can account for the loud first heart sound associated with closure of the valve. These same factors can also explain at least in part the presence of an opening snap, the noise produced in these patients by the normally inaudible opening of the mitral valve.

There is no systolic murmur in pure, isolated mitral stenosis. A pansystolic murmur may be heard, however, when tricuspid insufficiency is also present. This murmur is quite similar to that of mitral insufficiency and thus may suggest a mixed mitral lesion. Therefore, finding a pansystolic murmur

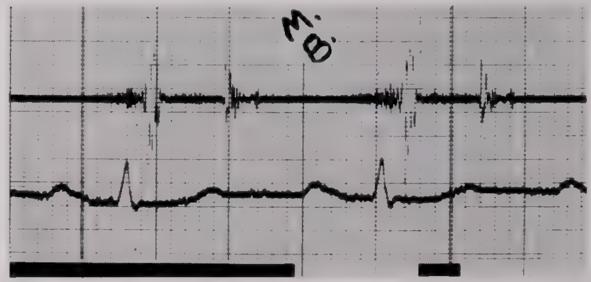

Fig. 1 — Phonocardiogram of a patient with severe mitral stenosis.
Upper tracing: Low frequency phonocardiogram taken at the apex. A crescendo presystolic murmur ends in a very loud first heart sound. In diastole an opening snap follows the second heart sound.
Lower tracing: Simultaneous recording of lead II of the electrocardiogram.

does not exclude the presence of pure mitral stenosis, since the cause may be tricuspid rather than mitral reflux.

Stenosis of the mitral valve affects both components of the second heart sound. The low cardiac output is probably responsible for the relatively quiet first or aortic component of the second heart sound which is produced by closure of the aortic valve. The pulmonary hypertension accompanying left atrial hypertension produces the accentuated second or pulmonic component of the second heart sound which occurs with closure of the pulmonic valve.

Opening Snap

As described above, an opening snap follows the second heart sound in mitral stenosis, tending to move progressively closer to the second sound as the stenosis becomes more severe. This finding together with time measurements of the first heart sound as discussed above has been used by Wells as a phonocardiographic index of the severity of mitral stenosis.[3]

Diastolic Murmur

When the cardiac rhythm is sinus, patients with mitral stenosis may exhibit a low-frequency, rumbling presystolic murmur and also a mid-diastolic murmur following the opening snap, both murmurs produced by the development of turbulence in the blood as it is forced through the narrowed valve. The palpatory phenomenon of a loud mitral rumble is a diastolic thrill.

The diastolic murmurs of mitral stenosis may be lost under two different conditions. First, the presystolic murmur disappears when the rhythm changes from sinus to atrial fibrillation, since the presystolic component depends on atrial contraction. Second, both the mid-diastolic and the presystolic mitral murmurs may be absent in the patient with congestive heart failure, the flow through the narrowed orifice being insufficient to generate the murmurs. These are the instances of so-called silent mitral stenosis. The murmurs may reappear, however, when compensation is regained and the cardiac

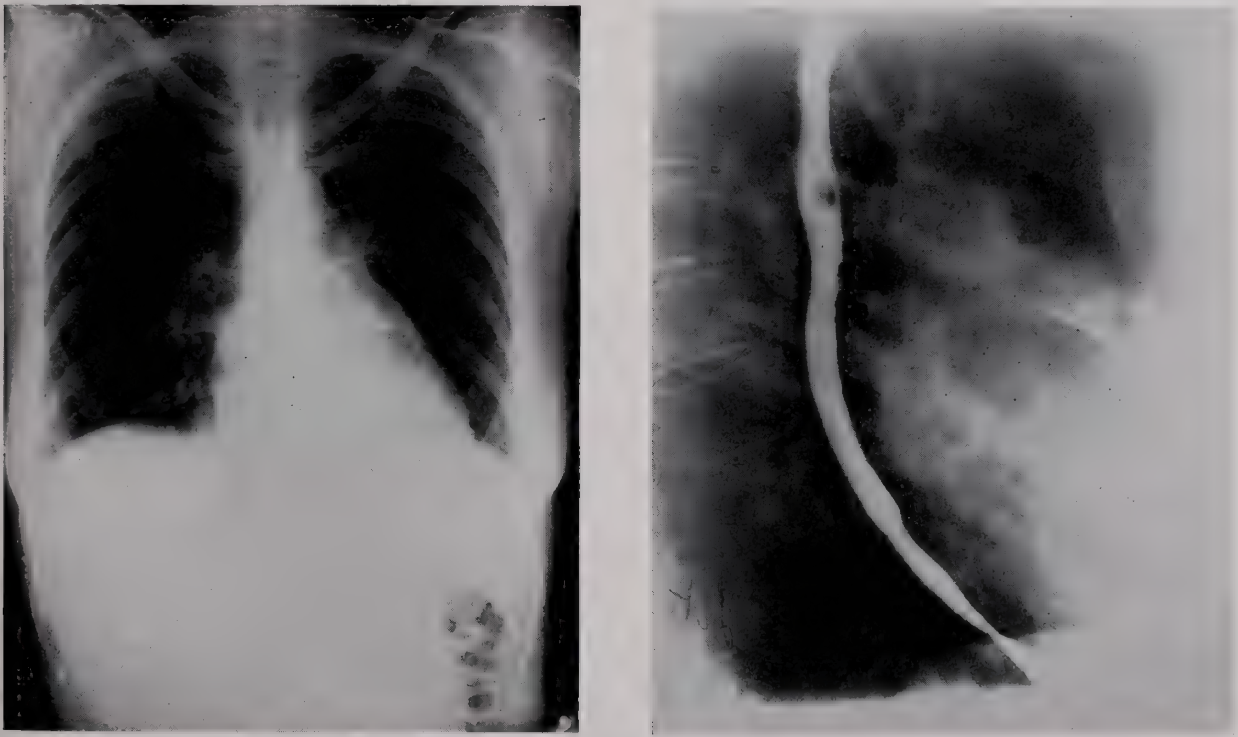

Fig. 2 — Thoracic roentgenograms of a patient with mitral stenosis. Left: posteroanterior view. The left atrial appendage can be seen along the left cardiac border. A double density is visible due to the left atrium which is enlarged and elevating the left mainstem bronchus. Right: lateral view. The enlarged left atrium is displacing the barium-filled esophagus posteriorly.

output improved.

Figure 1 shows the phonocardiogram of a patient with proved isolated mitral stenosis. The tracing illustrates several of the auscultatory events discussed above.

Roentgenographic Findings

Chest roentgenograms also reflect the derangements which occur in mitral stenosis. The increased left atrial pressure is accompanied by enlargement of this chamber. The enlarged left atrium can often be discerned on the posteroanterior film but is usually better seen on the lateral and right anterior oblique projections. The enlarged left atrium may displace the esophagus and elevate and compress the left main stem bronchus. Horizontal septal lines may be visible, particularly in the costophrenic areas. These lines are Kerley's B lines and indicate the presence of high pulmonary venous pressure. The pulmonary artery and right ventricle share in the pressure elevation present throughout the lesser circulation. The roentgenograms will disclose the resultant dilated central pulmonary arteries and the enlarged right ventricle. Figure 2 demonstrates some of the typical roentgenographic features found in a patient with mitral stenosis.

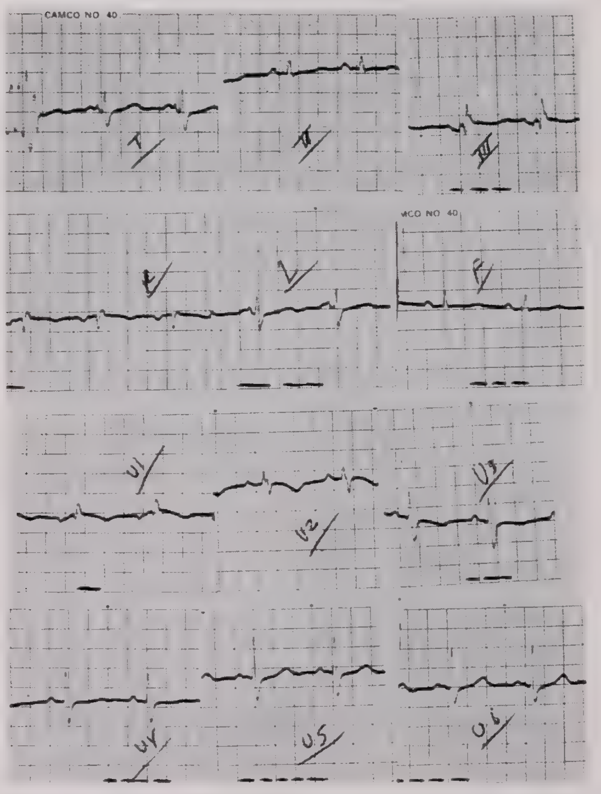

Fig. 3 — Electrocardiogram of a patient with mitral stenosis. The P waves are broad and notched. There is right axis deviation, a qR complex in V_1, and an Rs complex in V_6. The tracing is considered typical of that seen in mitral stenosis.

Electrocardiographic Findings

The electrocardiogram may show some characteristic features in mitral stenosis, as shown in Figure 3. The enlarged left atrium may cause the P wave to be notched in the limb leads and to have a broad, deep negative terminal deflection in lead V_1. In some cases the electrocardiogram may show evidence of right ventricular hypertrophy. It has been our experience, however, that the electrocardiogram in mitral stenosis not infrequently fails to be diagnostic.

Complications

The complications of mitral stenosis can often be explained by the underlying basic disease. If the pulmonary venous and pulmonary capillary pressures rise above a critical level, *pulmonary congestion* and edema ensue. The pulmonary vascular hypertension may result in *hemoptysis,* the bleeding point often being ruptured bronchial veins. *Lung infections* are probably encouraged by pulmonary congestion and compressed bronchi. Pressure on the left recurrent laryngeal nerve can cause *hoarseness.* If the pulmonary hypertension is extreme, the main pulmonary artery may become so dilated that the pulmonic valve becomes incompetent. The pulmonic insufficiency then produces the basal diastolic murmur known as the Graham-Steell murmur.

Patients with mitral stenosis are predisposed to *embolization* for at least two reasons. One is chronic left atrial and pulmonary congestion and engorgement; the second is the not infrequent complication of atrial fibrillation. Both factors act in setting the stage for embolization, either pulmonary or systemic.

Pulmonary emboli occur more frequently in mitral stenosis than is generally appreciated. Certainly a rapid progression of pulmonary hypertension and right ventricular hypertrophy with strain should alert one to the possibility. The diagnosis of pulmonary emboli can be difficult; diagnostic or even suggestive features may be absent in the electrocardiogram and chest roentgenogram until late in the course of the disease.

Systemic emboli may occur with dread effects. Emboli to the brain, kidneys and limbs are not rare. Mitral stenosis should be sought for and must be ruled out when a relatively young person suffers a cerebrovascular accident. Embolization can cause havoc in a person whose basic disease, mitral stenosis, may be amenable to surgical treatment.

Buckle Up

Plan Your Trip

Freeway driving leaves little time for decisions and offers little opportunity to retrace steps. Study highway maps and decide which entrance and exits you will use and where you will stop for food and fuel. And WATCH for your exit.

Know your route to the freeway, the interchange where you leave, and the route from that interchange to your destination.

Know where you will stop. Controlled access is the key to modern highways, but it means that service stations, restaurants, and motels will be available only by leaving the freeway.

Know freeway speed limits and laws.

Get Plenty of Rest Before Starting a Trip

Stop at least every two hours at designated rest areas off the freeway to stretch and relax.

Allow plenty of time to drive carefully and within the law.

Because its mission is to help man in the acts of life, in acts where, in spite of everything, man is alone and forcibly individual, in birth, suffering and death, medicine should remain one of the redoubts* of an imperilled individualism. . . . And let medicine not forget that it should remain independent if it is not to degenerate and lose its efficacy as well as its authority.—Georges Duhamel (1884-)

*See Test Your Word Score Page 1411.

Duty, then, is the sublimest word in our language. Do your duty in all things. You cannot do more. You should never wish to do less. — Robert E. Lee

---

No political organization since the world began ever developed a great industry. Even waterworks and the post office were developed by risks and energies of individuals pooling their resources under private management.

— Nation's Business

A High Calling*

Every sane human being is agreed that this longdrawn fight for time, which we call Life, is one of the most important things in the world. It follows therefore that you, who control and oversee this fight, and you who will reinforce it, must be amongst the most important people in the world. Certainly the world will treat you on that basis. It has long ago decided that you have no working hours that anybody is bound to respect, and nothing but extreme bodily illness will excuse you in its eyes from refusing to help a man who thinks he may need your help at any hour of the day or night. Nobody will care whether you are in your bed or in your bath, on your holiday or at the theatre. If any one of the children of men has a pain or a hurt on him you will be summoned. And, as you know, what little vitality you may have accumulated in your leisure will be dragged out of you again.

In all times of flood, fire, famine, plague, pestilence, battle, murder, and sudden death, it will be required of you that you report for duty at once, go on duty at once, and remain on duty until your strength fails or your conscience relieves you, whichever may be the longer period.

You remain now perhaps the only class that dares to tell the world that we can get nothing more out of a machine than we put into it; that if the fathers have eaten forbidden fruit the children's teeth are liable to be affected. Your training shows you daily and directly that things are what they are, and that their consequences will be what they will be and that we deceive no one but ourselves when we pretend otherwise.

Have you ever considered what a tremendous privilege that is? At a time when few things are called by their right names, when it is against the spirit of the times even to hint that an act may entail consequences — you are going to join a profession in which you will be paid for telling men the truth, and every departure you make from the truth you will make as a concession to man's bodily weakness, and not his mental weakness.—Rudyard Kipling

*Address to Students at the Middlesex Hospital, 1908.

WHAT'S YOUR DIAGNOSIS?

A 29-year-old housewife was admitted to the hospital for evaluation of easy fatigability, ill-defined abdominal pain, nausea, and aching pain in the back and legs, particularly the tibiae, of $2\frac{1}{2}$ years duration. She had been seen on several occasions during this period for more acute episodes of abdominal pain. Various diagnoses, such as acute appendicitis, peptic ulcer, and porphyria, were considered and discarded. Several L.E. cell preps were negative. There was no history of toxic or drug exposure.

On physical examination, several small posterior cervical lymph nodes were noted. The liver was enlarged 3 cm., and the spleen 2 cm., below the costal margins. There was slight fissuring around the mouth, and the hair was somewhat sparse around the anterior crown. Axillary and pubic hair were normal.

Routine blood counts, urinalysis, sedimentation rate, liver function tests, and sternal bone marrow were all normal. X-rays of the chest, upper GI, colon, and gallbladder were negative. Liver biopsy was being considered when further questioning into specific drug exposure led to the correct diagnosis.

What is your diagnosis? Turn to page 1386.

Iatrogenic Arterial Injuries*

JOHN J. BERGAN, M.D.**
Chicago, Illinois

THE PHYSICIAN'S role in diagnosis and treatment of injury and disease states is clear; less well defined is his part in causation of disease. Many practitioners are involved in diagnostic and therapeutic techniques which carry potential for injury. They are aware of the risks entailed and zealously guard against complications. They recognize that when injury to the arterial system occurs, a critical need exists for repair of the induced abnormality. In short, immediate recognition of iatrogenic arterial injury allows rapid repair with restoration of vital blood flow.

The frequency of iatrogenic arterial injuries is increasing, but such trauma is at least as old as recorded medical history. In the first century Galen referred to aneuryms caused by blood letting.[1] Later, arteriovenous fistulas were well documented by William Hunter in 1764 and described as ". . . what is produced in the mouth by continuing the sound of the letter R in a whisper. It *(the bruit)* is strongest at the very place where the vein was punctured and became gradually less perceptible from that part upward."[2] The terms varicose aneurysm and aneurysmal varix were defined by Hunter and the pathologic anatomy of the fistulous arborization was described.

In classification of iatrogenic arterial damage, classical categories serve well. These are divided into injuries with acute or chronic manifestations. External hemorrhage, expanding hematomas, pulsating hematomas, and/or sudden distal ischemia characterize acute injury and demand immediate attention. Later, occult hemorrhage may resolve into a false aneurysm; or simultaneous arterial and venous injury may allow arterial blood to flow directly into a

Aided by the Northwestern University Vascular Research Fund.

vein. These two entities, false aneurysm and arteriovenous fistula, become late results of iatrogenic arterial injury if they are unrecognized and untreated in the acute stage.

Arterial Injuries Associated with Orthopedic Disorders

Some of the most interesting and dramatic manifestations of arterial injury accompany orthopedic disorders because of the peripheral nature of orthopedic surgery where large vascular channels lie adjacent to traumatized bone. Deep, relatively fixed vessels are vulnerable[3] to damage accompanying fractures or fracture treatment. Sometimes these injuries attend placement of the hardware of fixation. Bassett and Houck describe such an instance in which a false aneurysm of the deep femoral artery was caused by an overly long screw used to hold a femoral plate.[4]

Among orthopedic operations[5] there were 59 related to surgery of intervertebral discs, 51 accompanying excision of ganglion of the wrist, 32 occurring during arthrotomy of the knee, and 26 following triple arthrodesis of the ankle.

Intervertebral Disc Operations

The location and relative fixation of the aorta and the iliac veins make these vessels particularly liable to injury during removal of the L-4-5 lumbar disc. If disc degeneration involves the anterior wall, it may fail to offer a firm barrier to the exploring rongeur forceps. If the forceps are allowed to penetrate, tearing of the veins or arteries anterior to the spine may occur.[6] A mortality rate of 47 to 61 percent attends such a complication.[7,8]

If injury to a major artery occurs during disc surgery, bleeding may appear in the disc space. This is present in about one half of reported cases. Later, shock develops, due to retroperitoneal hemorrhage. This usually appears as the patient is turned from the prone to the supine position.[9] Heroic measures may be necessary to support life.

If the artery and vein are injured together during disc surgery, immediate hypotension may not be seen, since blood lost is quickly returned to the circulation. However, signs of distal venous hypertension, cardiomegaly, widening of pulse pressure, appearance of an abdominal systolic to-and-fro murmur

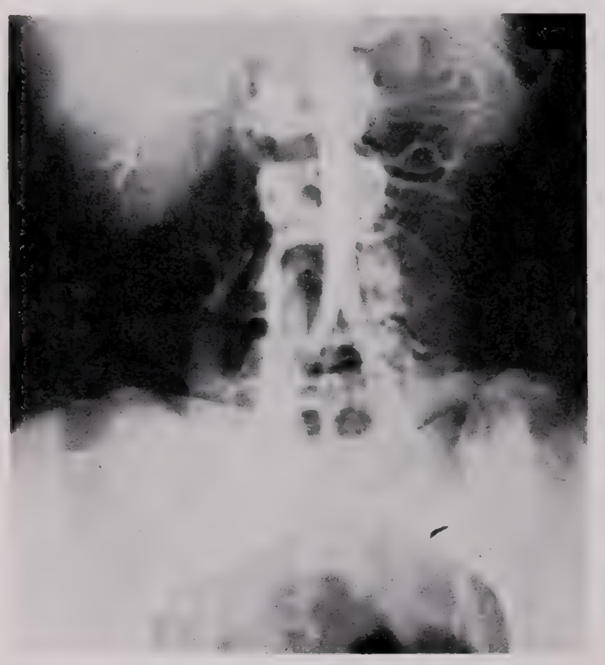

Fig. 1 — This aortogram, performed 19 years after appendectomy, shows an arteriovenous fistula between the ileocolic artery and the superior mesenteric vein. This portal system a-v fistula produced no cardiac abnormality.

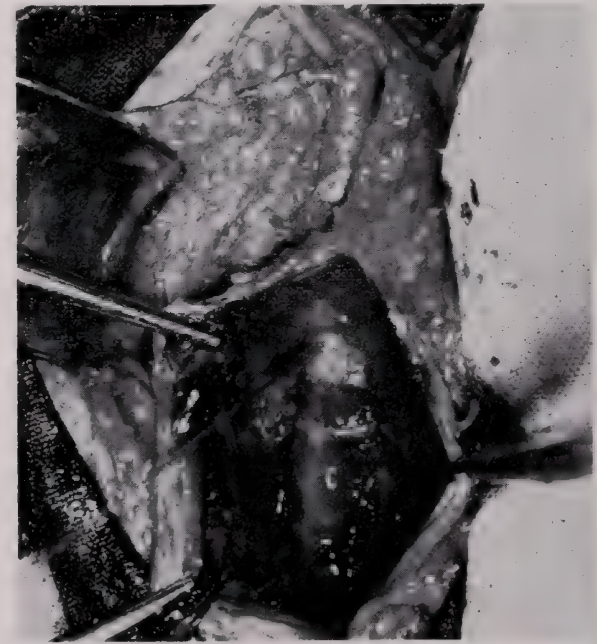

Fig. 2 — The false aneurysm caused by the arterial catheter has been opened. The femoral artery puncture site and its forceful jet of blood are well seen as the aneurysmal walls are retracted.

and eventual cardiac failure should lead to a rapid diagnosis of aorto-iliac arteriovenous fistulization.

Lateral Meniscus Operation

Other arterial injuries accompanying orthopedic operations include injuries to the lateral inferior genicular artery during removal of the lateral meniscus of the knee and arteriovenous fistula of the superior gluteal vessels caused by intramedullary femoral rodding.[10,11]

Excisional therapy in bone and joint surgery, much like major ablative procedures done elsewhere for malignancy, can cause arterial injury, as illustrated by the following case:

Case Report

Case No. 1

Biopsy of a recurrent giant cell tumor of the distal femur in a 48-year-old woman had shown this lesion to be benign. During excision of the large tumor, the popliteal artery was transected and repaired. Postoperatively the foot was pale, cold, pulseless, mottled and anesthetic despite administration of vasodilators and heparin. A secondary repair of the vessel was accomplished after excising the previously traumatized and sutured artery. Peripheral pulses, distal sensation and function were restored.

Determination of need for secondary arterial reconstruction was based upon recognition of traditional manifestations of ischemia, especially loss of epicritic sensation and motor function. Division of adjacent collateral vessels gave additional length to allow anastomosis without tension.[12]

Arterial Injury Associated With Abdominal Surgery

Since almost every operation can be associated with major arterial trauma, it is surprising that difficulties arise as seldom as they do.[13] Acute injury to vital arteries must be recognized and successfully treated immediately if life is to be preserved. Such instances arise when the hepatic or superior mesenteric artery is involved.

Case No. 2

During elective cholecystectomy, hepatic artery laceration was recognized. Hemorrhage was controlled by packing, and vascular consultation was obtained. Hemostasis was achieved by application of Potts vascular clamps. The hepatic artery was skeletonized,* the laceration was excised and the artery repaired with interrupted sutures. During an uneventful postoperative recovery, prophylactic antibiotics were administered.

Immediate recognition of the potentially fatal injury allowed rapid repair without observable hepatic ischemic damage.

Arterial Injury with Other Operations

Late manifestations of arterial injury can follow virtually every major operation. Late arteriovenous fistulas after thyroidectomy, mastectomy, splenectomy, nephrectomy, gastrectomy, hysterectomy and amputation are listed.[14] Chief offenders are operations in which a major vascular pedicle is ligated as a single unit. The mass ligature is a notorious producer of arteriovenous fistulas, as is the transfixion ligature. In the latter instance, the artery and vein are pierced simultaneously and arterial hemorrhage is decompressed into the venous circulation.

Case Report: A 34-year-old woman was found to have a loud machinery murmur over her entire abdomen. An appendectomy had been performed at age 15. No cardiac abnormality was present nor was hepatic dysfunction noted. An aortogram showed communication of the ileocolic artery and a branch of the mesenteric vein (Figure 1).

Arteriovenous fistulas involving the portal system are not common but can follow splenectomy or gastrectomy.[15,16,17] While these can produce portal hypertension and hepatic congestion, systemic cardiovascular responses are tempered by the liver acting as a circulatory buffer.

Arterial Injury Associated with Diagnostic Procedures

The most common type of iatrogenic arterial injury today follows diagnostic procedures which necessitate arterial puncture. Among these are cardiac catheterization, catheter angiography and direct arterial angiography. Complications following such investigations may be related to contrast media, premedication and even to the underlying disease process. These are not under consideration in this report.

In surveying 300 radiologists by questionnaire, Lang discovered 81 serious complications in 11,402 investigations utilizing the

---

*See Test Your Word Score Page 1411.

Seldinger technique.[18] This certainly must represent the minimum risk of this type of manipulation. Lang found that minor complications of arterial spasm, local hematoma and vessel puncture were frequent (3%) but did not cause more than transient minor discomfort.

The most common single serious complication of arterial catheterization is thrombosis. This develops at the site of needle puncture, is associated with poor vascular status of the patient, long duration of the diagnostic procedure and inexperience of the investigator. Low output cardiac states contribute to frequency of post-catheterization thrombosis. Other complications also occur.

Case No. 3

This 60-year-old woman underwent a prolonged and difficult cardiac catheterization for diagnosis of aortic valvular insufficiency. Her blood pressure was 180/50. Twenty-four hours after the study a rapidly expanding pulsating hematoma of the groin developed at the site of one of the femoral artery punctures. This was repaired surgically.

Atherosclerosis, a pounding Corrigan pulse (water hammer type pulse), and prolonged arterial catheterization all combined to effect rupture of the femoral puncture site.

Case No. 4

Following uneventful cardiac catheterization, a groin hematoma persisted for three months in this 34-year-old male. Suddenly the character of the mass changed; it enlarged, became tender and caused a hip flexion contracture. At surgery the false aneurysm was opened and the puncture wound of the common femoral artery closed with a single suture (Figure 2). Subsequently this artery was used during cardiopulmonary bypass while the mitral valve was being replaced.

Despite an uncomplicated, brief arterial catheterization, performed by an experienced investigator, a false aneurysm developed. The case illustrates the inexorable progression of an aneurysm once it becomes established.

Other complications of retrograde arterial catheterization include dissecting aneurysm of vessels and subintimal, intramural arterial hematomas.[19,20] These combine to form the largest single category of arterial injury now seen by surgeons interested in vascular repair.

While catheter injuries of arteries are important, single needle punctures are also implicated in causation of arterial injury. Such injuries have followed thoracentesis, trigeminal nerve injections and even diagnostic venous puncture.[21] More rarely, an arteriovenous fistula has been encountered following vertebral arteriography.[22] This has not been seen by us following brachial retrograde angiography.[23]

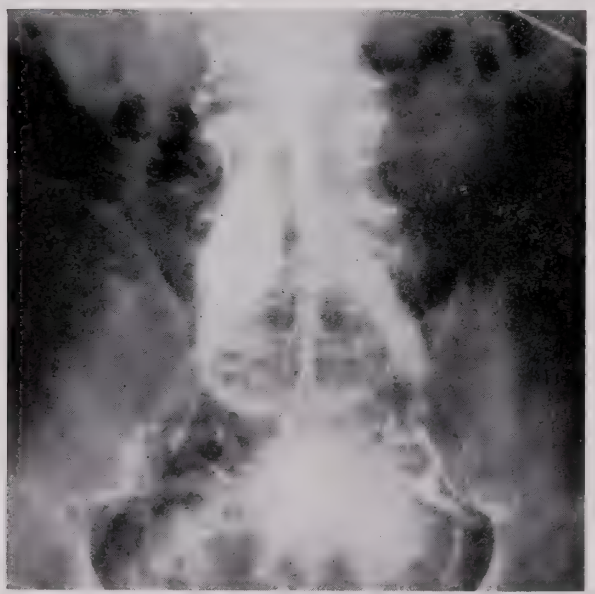

Fig. 3 — This aortogram shows a false aneurysm of the right iliac artery following a chronic disruption of an artery-graft suture line placed five years previously.

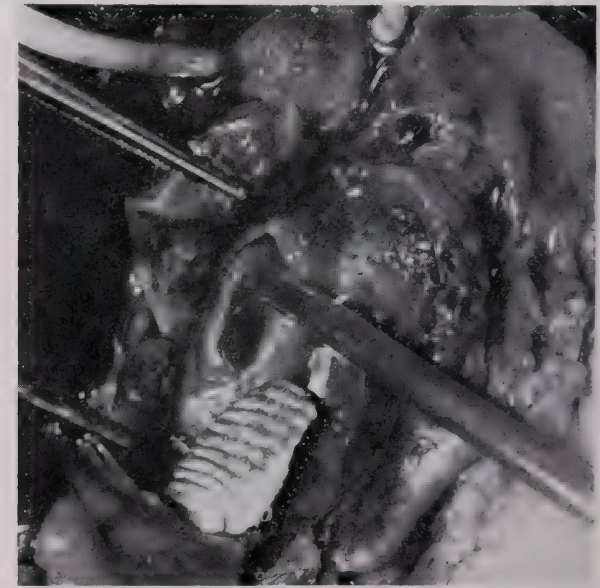

Fig. 4 — At surgery the graft is seen lying free within the false aneurysm. The disruption is attributed to failure of the silk suture and not to arterial degeneration.

Arterial Injury Associated With Vascular Surgery

In addition to technical problems of vascular reconstruction, the vascular surgeon encounters iatrogenic arterial injury as a result of graft infection with suture line disruption, autogenous venous patch blow-out and late failure of graft artery suture line.

Infection following graft implantation is a tragedy with horrible implications. Robert Shaw has said that if graft infection develops, one ". . . loses the patient or a large part of him." Principles of dealing with such problems include bypass of the infected graft and excision of the infected foreign body.

Less well known is the entity of central necrosis of an autogenous venous patch with massive postoperative hemorrhage.[24] In this complication the vein wall undergoes irreversible ischemic necrosis during implantation as an arterial patch. Blow-out of the central necrotic area occurs up to 48 hours after arterial reconstruction.

False aortic aneurysms adjacent to graft-artery suture lines are being seen by vascular surgeons with increasing frequency. These occur months or years after graft placement, behave exactly like true aortic aneurysms, and result from continued arterial degeneration, loss of suture strength, relative nonporosity or loss of strength of the graft material, such as nylon or orlon.[25]

Case No. 5

This 72-year-old man was found to have a pulsating lower abdominal mass five years after placement of an iliofemoral bypass graft. Aortography defined the lesion and surgical exploration revealed complete artery-graft suture-line disruption with false aneurysm formation (Figures 3 and 4).

A strong arterial wall and intact graft were found at re-exploration. The suture material used during graft implantation was silk. Apparent nonhealing of graft to artery occurred and, as the silk lost strength, the graft pulled away from the artery.

While continued arterial degenerative changes doubtless contribute to development of these post-reconstruction false aneurysms, the materials used in repair are also important. Recent development of dacron and polyethylene suture has allowed use of materials which do not lose tensile strength after implantation.

Conclusions

Physicians cause injury to arteries now just as they did in the time of Galen. Instruments and indications for violation of bodily integrity change, but the fact of arterial injury caused by the attending doctor remains. At this time the largest single category of arterial injuries caused by a physician follows arterial catheterization and is largely due to the increased use of this valuable diagnostic tool. Other causative factors include lack of experience of the physician performing the examination, technical difficulties of the procedure and long duration of the catheterization. It is to be expected that the incidence of this type of injury will decrease, but that the frequency of its occurrence will increase. This will be due to the value of catheter angiography in diagnosis and treatment of disease states and the increased use of the technique.

Just as the frequency of iatrogenic arterial injury can be expected to increase, the frequency of repair of such injury should increase. It is clear that major complications in the past have occurred in part because of delay in recognizing and effecting arterial repair. Since early repair is relatively easy before distal irreversible thrombosis occurs or exsanguinating hemorrhage develops, it is to be expected that restoration of arterial integrity will be the standard of acceptable therapy for this condition in the future.

Photographic Contest

The Editors of MINNESOTA MEDICINE, in collaboration with the Doctors' Photographic Society of Minneapolis, take pleasure in announcing a monthly photographic contest. The contest is to promote an interest in photography in the medical profession. First prize each month will be publication in full color of the winning picture in MINNESOTA MEDICINE.

The following rules will govern the conduct of the contest:

1. Only doctors of medicine are eligible to submit pictures, and the picture must have been taken or composed by a physician.
2. Each contestant may submit not more than two pictures each month.
3. Only color transparencies, 35 mm. to 2¼", can be considered.
4. Each slide should be labeled with the maker's name, address, and the identifying title.
5. Slides should not be mounted on glass, but can be protected in plastic sleeves or envelopes.
6. Each entry must be accompanied by a self-addressed, stamped envelope if return of the picture is desired. Returns will be made shortly after the close of the contest each month. The winning photograph will be retained but will be returned after it has been used.
7. The deadline date for entry will be the 10th of each month and the winner of each month's contest will be announced in MINNESOTA MEDICINE in the subsequent issue. The date of publication will be three to six months in advance.
8. There will be no limitation on subject material except as indicated in item 10.
9. Model releases will be requested of winners where appropriate.
10. Judges will be selected by the editors of MINNESOTA MEDICINE and the Doctors' Photographic Society. The judges will be guided by the precepts of the Photographic Society of America, and winners will be based on appropriateness, interest, impact, and technical excellence.
11. The editors of MINNESOTA MEDICINE and the Doctors' Photographic Society cannot be responsible for entries lost or damaged, but every effort will be made to protect submitted pictures.

Your pictures are hereby invited. Please submit pictures to:

Voided Urine Cultures in Women

A Study of 425

B. R. BREITENBUCHER, M.D.
Minneapolis, Minnesota

In recent years the value of urine cultures obtained by catheterization and planted on broth cultures or other non-quantitative means has been rightfully questioned.[1-5] Observations that the urethra is not sterile as was once assumed lend credence to the idea that bacterial growth per se on cultures of voided urine need not be indicative of urinary infections.[6-9] It also follows that passage of a catheter through a contaminated urethra may result in a growth of bacteria in the culture medium which is not indicative of a urinary tract infection. Furthermore, thrusting a catheter through the bacterial flora in the urethra may introduce these bacteria into the bladder. It is estimated that a clinical urinary tract infection results from a single catheterization in two to four percent.[10,13]

Marple[11] in 1950 made use of a colony count method in quantitating bacteriuria, but the method did not come into widespread use until recent years. Many studies have now been carried out which indicate the value of a quantitative estimate of bacteria in urine cultures as a means of differentiating contaminants from the bacteria involved in an active urinary infection.[1,2,3,10,12] What is found in a urine culture is not so important as how many bacteria appear in the culture. It has long been acknowledged that clean, voided specimens in males are associated with a minimum amount of contamination, but there has been some reluctance to accept the idea that voided urine cultures in women are equally uncontaminated.

A growing number of studies have indicated, however, that clean voided urine cultures are quite valid in women.[13-16] Since catheterization of female children may be very traumatic, psychologically if not physically, application of this method to children would be welcome.[17]

There seems to be unanimity of opinion

that less than 1,000 bacteria per cc. of urine are indicative of contamination, and greater than 100,000 bacteria per cc. as pathognomonic of urinary tract infection. There is no agreement on the significance of counts between 1,000 and 100,000. Some feel that counts above 10,000 are significant; others place their significant count much higher.

The first purpose of this study was to try to ascertain whether or not voided urine cultures would be clinically useful. The second purpose was to determine what numbers of bacteria would be considered normal and abnormal by our method. The patients in the study were all women in a general hospital,* their ages ranging from one to ninety-one years.

The cooperation of the medical staff was obtained in order to get a large number of voided cultures in women who were clinically free of urinary tract infections. Voided cultures were also obtained from patients who had clinical urinary tract infections. The results of all the voided urine cultures obtained from women during the period of the study, covering the approximately two-year period from 1959 to 1962, were recorded in the laboratory. The author then reviewed the charts of all the patients involved and categorized the patients according to whether clinical urinary tract infections did or did not exist, based on the evidence on the chart. Aside from the effort to obtain a large number of clinically infection-free patients, there was no attempt made to select the patients. All female patients with voided urine cultures during this period of time are included in the study. There were 308 cases considered to be clinically free from urinary tract infections and 117 cases with a diagnosis of urinary tract infections. Cystitis was the most common diagnosis. There were also a number of cases of pyelonephritis. In an additional 21 cases there was insufficient data on the chart to permit categorization with reasonable assurance, or the clinical diagnosis or absence of diagnosis in the author's opinion conflicted with the data in the chart.

Method

The patients are instructed to cleanse the external genitalia thoroughly with Phisoderm. Some authors have described rather elaborate cleansing and disinfecting regimens.[16,18] However, we have not used antiseptics or antiseptic soaps, as we believe that the use of antiseptics will not add materially to a thorough cleansing and rinsing. The patient is next instructed to void the initial urine into a urinal and then to discard it. The last part of the urine is then voided into a sterile, large-mouthed jar. This urine is immediately sent to the laboratory and cultured within fifteen minutes. Since urine itself is a good culture medium, a spuriously high count may be obtained in a urine which is allowed to stand before culturing.

The Culture Media

In the laboratory the freshly collected urine cultures were innoculated on appropriate media as soon as they were received. In general, two types of media were used. One plate consisted of a selective medium for the isolation and preliminary identification of gram-negative rods. The selective plates used were Tertigol-7 Agar, Eosin Methylene Blue Agar or Desoxycholate Agar. Urine was also innoculated on a blood agar plate containing either sodium azide or phenyl ethyl alcohol to inhibit gram-negative rods.

The Method of Counting

During the initial part of the study colony counts were performed by making a 1:10 dilution of urine in saline and innoculating 0.1 cc. on the surface of the appropriate plates and spreading the urine evenly over the plate surface with a bent glass rod. Later in the study the innoculation of the plates was made with undiluted urine, using a calibrated platinum loop having a 4 mm. inside diameter capable of delivering 0.01 ml. of urine. The urine was spread evenly over the surface of the plates. Colony counts of gram-negative and gram-positive cocci were made from the appropriate plates at the end of twenty-four hours. Further isolation and identification of the gram-negative rods were made by the usual biochemical techniques. Identification of enterococci was made by innoculation of suspected colonies into a fluid medium containing dextrose, sodium azide and Brom Cresol Purple (SF Medium, Baltimore Biologic Laboratories). Staphylococci were identified on the basis of pigment production, hemolysis and coagulase reaction.

---

*St. Mary's Hospital, Minneapolis, Minn.

Results

The Clinically Uninfected Group

The results of the cultures in the 308 females deemed to be clinically free from urinary tract infections are shown in Tables 1 and 2. The organisms shown in Tables 1 are all other than Staphylococci. It may be seen that 87% of these urines had colony counts of 0-1000 per cc., and 97% had colony counts of 0-5,000 per cc. Counts of 0-10,000 per cc. appeared in 99% of these cases. There were two cases where the counts ranged from 10,000 to 20,000 and one case with a pure culture of 30,000 E. Coli per cc. Of course one may question whether this latter case might not, in fact, represent a sub-clinical urinary tract infection; but there was no definite evidence to support this.

Staphylococci were cultured in 93 instances. It should be noted that these cultures and 234 non-Staphylococci cultures add up to more than 308 total cultures since in some instances more than one organism was cultured from a given urine. The colony counts of the cultured Staphylococci are shown in Table 2. It may be seen that 50% had counts of 0-1,000 per cc.; 72% had counts of 0-5,000 per cc.; 80% had counts of 0-10,000 per cc. In 98% the counts were 50,000 or less. In one instance there were 100,000 coagulase negative Staphylococcus albus per cc., and in another, 150,000 Staphylococcus aureus.

The types of organisms cultured and their relative frequency in the 308 clinically uninfected cases are shown in Table 3.

The Clinically Infected

Table 4 shows the colony counts obtained in 125 cases deemed to have clinical urinary tract infections, most of which were diagnosed as cystitis. There were some cases of pyelonephritis. In eight cases two organisms were considered to be etiological in the same clinical infection. It is seen that 74% of the cultured bacteria had colony counts greater than 100,000 bacteria per cc. Ninety percent of these cultures yielded greater than 75,000 per cc.; 93% had counts greater than 50,000 per cc.; 98% had counts greater than 10,000 per cc. Table 5 lists all of the organisms encountered in these cases with their frequency of occurrence. In only one of the cases with Staphylococci cultured was this organism felt to be etiological. In this case a coagulase positive Staphylococcus aureus was isolated in pure culture with a colony count of 100,000 per cc. In some cases organisms such as Enterococci, Coliform and Proteus were encountered in low counts of 10,000 or less along with organisms in larger numbers which were considered to be the etiologic agent of infection. This, of course, is the advantage of colony counts as they more positively identify the significant bacteria. In two cases additional organisms, E. Coli and Proteus, were found in larger numbers, the count being 45,000 per cc. in both cases. The significance of these organisms in the infective process is uncertain. In eight cases two organisms were considered to be etiological. All of the bacterial counts in these cases were 100,000 per cc. or over, except in one case where 90,000 Proteus per cc. were cultured. It should be noted that for the sake of simplicity, the Coliform group includes all bacteria identified as E. Coli., Paracolon, Klebsiella, Aerobactor and E. Freundia. Similarly the Pseudomonas group includes bacteria identified as Pseudomonas and Alkaligenes. Table 6 lists the organisms which were considered to be offending agents along with their frequency of occurrence.

TABLE 5
Organisms Encountered in 117 Urinary Tract Infection Cases (144 Organisms)

	Number of Cases Where Found	%
*Coliform Group	93	65
Proteus	21	14
Enterococcus	16	11
**Staphylococcus Albus	8	6
†Pseudomonas	3	2
‡Staphylococus Aureus	2	
Alpha Streptococcus	1	

*Includes E. Coli, Paracolon, Klebsiella, Aerobacter, E. Freundia.

**All of these were found with other organisms. In none was Staphylococcus Albus considered etiological.

†Includes Pseudomonas and Alkaligenes.

‡In only one was the Staphylococcus considered etiological (pure culture 100,000/cc).

TABLE 6
Organisms Considered Etiological Agents in 117 Urinary Tract Infections*

Coliform	90	72%
Proteus	18	14
Enterococcus	12	10
Pseudomonas	3	2
Staphylococcus Aureus	1	1
Alpha Streptococcus	1	1

*In 8 cases more than one organism was felt to be etiological.

There were three cases with counts of less than 10,000 organisms per cc. in the group of patients who had a clinical diagnosis of urinary tract infection. One case was diagnosed as hemorrhagic cystitis. Klebsiella, 7,500 per cc., were cultured from this urine. The other two cases were diagnosed as "chronic urinary tract infection." Both had had frequent instrumentation and treatment previously. One culture yielded Pseudomonas 1,200 per cc. and the other had Proteus 2,600 and E. Coli 2,400 per cc. It seems quite possible that the infection may have been in a relatively quiet phase in both of these cases at the time the culture was taken.

Discussion

From the data accumulated there seems to be reasonable evidence that this method of culturing urine can be reliably used in females. The ease by which urine collections can be made certainly has much to recommend it from the point of view of the nursing service and the patient. There is no danger to the patient from the urine collection, and follow-up cultures may be taken as necessary with no concern about ill effects. A very little more work is required from the laboratory; but this seems amply justified from the results obtained. The method is not so complicated that it cannot be used in any office or hospital with facilities for doing simple bacteriology. The infecting organisms may be more reliably determined and therapy therefore more accurate. There seems to be a wide separation between normal and abnormal numbers of bacteria which may be encountered in the urine, so that most of the time the results can be directly interpreted. Figure 1 shows a graphic representation of all the data obtained in this study from the cases both with and without clinical urinary tract infections. We believe that despite the fact that large numbers of Staphylococci may be cultured from the urine, clinical infection with this organism is rare. There was only one case in this series which was considered to be due to Staphylococcus.

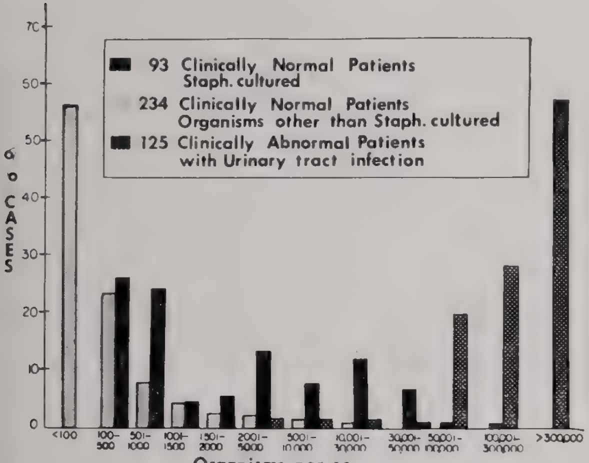

Figure 1

Conclusions

From the data it seems fair to say that a colony count of 10,000 or less in women may be regarded as normal with few exceptions. Counts of 1,000 or less are probably never associated with infection. A rapid urine flow with resultant dilute urine may lower the count. The urine should be in the bladder long enough for bacteria to multiply. A very acid urine pH may inhibit bacterial multiplication. An obstructed ureter may not allow the infecting bacteria to enter the bladder. Certain fastidious organisms (Group A Streptococci, some Streptococcus viridans, occasional Staphylococci or Enterococci) may grow poorly in urine. A bacteriostatic agent in the urine will lower the bacterial count.

On the other hand, colony counts of over 100,000 per cc. (Staphylococci excepted) seem invariably to indicate urinary tract infections, as noted by previous investigators. From the data presented here it would seem reasonable to accept counts of greater than 75,000 per cc. as definitely positive. Colony counts of 50,000 to 75,000 per cc. are probably significant. Counts of between 10,000 and 50,000 represent a grey zone. Most of these will probably be associated with urinary tract infection. A few counts in this range, however, may be normal. As in most laboratory tests, a generous pinch of medical acumen must be added. In the final analysis clinical judgment will prevail.

Man's evolution to an upright position should be viewed in proper perspective. It took a billion years to develop low back pain. — Changing Times

Clinical Notes from Hippocrates' "Epidemics"

Case II: Silenus lived on the Broadway near the premises of Eualcidas. In consequence of exertion, drinking, and unseasonable exercises, he was seized with fever. Pain began in the loins.* Feeling of weight in head, and stiffness of neck. On first day discharge from bowel was bilious, unmixed, frothy, high-coloured, and abundant. Urine dark, with dark sediment. Thirst, dry tongue. No sleep at night.

Second day. Acute fever, stools more abundant, thinner and frothy; urine dark; bad night; slight delirium.

Third day. All symptoms exaggerated. In abdomen on both sides an oblong area of tension without anything solid below it, and reaching to navel. Stools thin, darkish. Urine turbid, darkish. No sleep at night; much talking, laughing, singing; unable to check himself.

Fourth day. Same.

Fifth day. Stools unmixed, bilious, smooth, fatty; urine thin, transparent; mind occasionally clear.

Sixth day. Sweated a little about the head; extremities cold and livid; much restlessness, no passage from bowels; urine suppressed; acute fever.

Seventh day. Speechless; extremities could not be warmed up; no urine passed.

Eighth day. Cold sweat all over; and with it red spots (exanthemata), round, small, like acne, persisted without subsiding. From bowels after slight stimulus abundant, thin, and as it were unconcocted matter was passed, with pain. Urine irritating and passed with pain. Extremities showed little warmth. Scanty sleep; tendency to coma; speechless; urine thin and transparent.

Ninth day. Same as before.

Tenth day. Drank nothing; comatose; scanty sleep. Discharges from bowel as before; urine thickish, coming away in bulk; on standing, left a white deposit, like meal. Extremities again cold.

Eleventh day. Death.

In this case, from the beginning and throughout, the breathing was deep and infrequent. Constant throbbing in abdomen. Age about twenty.

---

ANSWER TO WHAT'S YOUR DIAGNOSIS

(From page 1374)

Chronic Vitamin A intoxication. The patient had been taking between 50,000 and 100,000 units of Vitamin A for 4 or 5 years, originally prescribed for acne. Following this disclosure, her serum Vitamin A level was found to be 270 I.U. (normal less than 200). Definite symptomatic improvement occurred within a week after withdrawal of this medication. It is of interest that he patient did not think of Vitamin A as a drug, and hence did not mention it when asked originally about medications.

Early Ambulation

Long ago I learned from my father to put old people to bed only for as short a time as was absolutely necessary, for they were like a foundered horse; if they got down it was difficult for them to get up, and their strength ebbed away very rapidly while in bed. — Charles Mayo

Congenital Nonspherocytic Hemolytic Disease

With Erythrocyte Glucose-6-Phosphate Dehydrogenase Deficiency

IRVING LERNER, M.D.*
ALFRED DOSCHERHOLMEN, M.D., Ph.D.*
Minneapolis, Minnesota

A DEFICIENCY OF the enzyme glucose-6-phosphate dehydrogenase in the red cell has been well recognized as the underlying abnormality responsible for hemolytic episodes in a substantial group of patients when exposed to a variety of drugs.[1-5] Originally described as a problem of "primaquine** sensitivity," it was found that in addition to antimalarial drugs, agents as diverse as the fava bean, chloramphenicol, and aspirin could precipitate an attack of hemolysis in these patients. The attacks are readily reversible if the inciting agent is discontinued and are self-limited when it is continued without an increase in dosage.[1,3-6] Even when these patients are not exposed to such an agent, a significant proportion have been found to have a red cell life span about 25 per cent less than normal and a reduced osmotic fragility, although they are usually not anemic.[1,7,21]

In contrast to this comparatively common disorder, more recently a complete or almost complete absence of this enzyme in the red blood cells has been described[8-21] in another group of patients. Characteristically chronic hemolysis is present in this group with severe exacerbations of hemolysis or episodes of bone marrow erythropoietic arrest following febrile illnesses. The exact relationship between this enzyme-deficiency, congenital nonspherocytic hemolytic disease and the primaquine-sensitive variety has not been clearly established. This report describes a typical case of the congenital nonspherocytic hemolytic type with post-splenectomy thrombotic complications which had not been observed previously in this condition.

Methods

Routine clinical tests were carried out according to standard laboratory techniques.

---

*From Section of Hematology, Department of Medicine, Minneapolis Veterans Hospital and Department of Medicine, University of Minnesota, Minneapolis, Minnesota.
**See Test Your Word Score Page 1411.

Special laboratory investigations included the autohemolysis test,[22] the Heinz body test,[23] determination of the reduced glutathione and the glutathione stability test,[24] measurement of erythrocyte glucose-6-phosphate dehydrogenase,[25] acid phosphomonoesterase,[26] and pyruvate kinase.[27]

Case Report

A 33-year-old white male of German ancestry was admitted to the Minneapolis Veterans Hospital for the first time in August 1963 for treatment of a residual, superficial thrombophlebitis.

Childhood History

At the age of three, following an upper respiratory infection, the patient was found to be "severely jaundiced and anemic." He was hospitalized and recovered uneventfully without blood transfusion. Despite the usual childhood diseases, the patient had no similar attack until he was fourteen years old. Then, in November 1944, over the course of a few days, he suffered profound fatigue, cough, nausea, chills and fever, while becoming progressively more pale and yellow. No history of prior drug or toxic exposure was elicited.

Childhood Physical Findings

He was referred to the University of Minnesota Hospitals where he was found to be an acutely ill child, restless, disoriented, with a temperature of 102° F. and a pulse of 160/min. Pertinent physical findings were marked pallor, icterus, and two-fingerbreadths hepatosplenomegaly.

Initial Laboratory Findings

Admission laboratory data included a hemoglobin of 2.1 g/100 ml., a wbc. of 9,250/mm^3, a platelet count of 380,000/mm^3, a reticulocyte count of 0.7%, and an icterus index of 12. Marked anisocytosis was observed in the peripheral blood smear, but there was no mention of spherocytes then or at any later time. The patient was transfused with 1300 ml. of whole blood over the next several days, with a prompt reversal of the bone-marrow arrest, as reflected in a reticulocytosis of 15% on the fifth hospital day, followed by an increase in the hemoglobin to 10.6 g/100 ml. Two fecal urobilinogen determinations on specimens collected during the transfusions were 2,960 and 3,360 Ehrlich units/100 g. Osmotic fragility was normal at this time. The diagnosis of a familial hemolytic anemia was made, and the patient advised to have an elective splenectomy after he had completely recovered from the attack.

Progress

In March 1945 the patient was readmitted and a 502-gram histologically normal spleen was removed. Preoperatively the platelet counts ranged between 280,000/mm^3 and 450,000/mm^3. In the immediate postoperative period the platelet count rose to 850,000/mm^3 but then promptly returned to the 450,000/mm^3 range.

For the next fourteen years the patient was asymptomatic, serving a two-year term in the Marine Corps during the Korean conflict without undue hardship. During this period his friends occasionally commented that his eyes were yellow at times when he felt unusually fatigued or suffered from an upper respiratory infection, but these episodes were never serious enough to warrant a physician's attention. In 1959, at the age of 28, the patient developed deep thrombophlebitis of the left calf for which he was hospitalized and treated with heparin. Evidence of the disease cleared rapidly, but in 1961 he developed a similar process in the right calf, and again there was a good response to heparin. In June 1963 the patient developed bilateral thrombophlebitis of the great saphenous veins. With heparin and oral anticoagulants there was considerable improvement except for residual pain in the inner aspects of his thighs. There was no history suggestive of pulmonary embolization during any of these episodes, nor was the patient aware of cyanosis or unusually severe shortness of breath.

Family History

The patient's father had died at age 39 from what was thought to be an "infection of the heart" and his mother at age 44 from a malignancy of unknown type. One sister is well and free of jaundice or anemia. All five of the patient's children were jaundiced at birth, but this condition was very transient and they have developed uneventfully since.

Adult Physical Findings

On physical examination the patient was afebrile with a blood pressure of 130/80 mm Hg. The pulse was 84/min. with many premature beats. He was a well-developed, cooperative young man in no distress. There was no apparent jaundice. The heart was normal in size with an accentuated second pulmonic sound, a right ventricular heave and a pulmonic ejection click. Examination of the abdomen revealed a well-healed left upper quadrant scar and no hepatomegaly. All peripheral pulses were present but substantially reduced. A small, chronic ulcer of the left calf was evident and both greater saphenous veins in the thighs were firmly thrombosed and surrounded by relatively mild inflammatory reactions. There was no evidence of deep vein phlebitis.

Laboratory Studies

Initially the hemoglobin was 15.8 g/100 ml., the leukocyte count 11,850/mm^3, the platelet count 406,000/mm^3 and the reticulocyte count 8.8%. The red blood cell indices were normal (MCH. 33 $\mu\mu$g, MCV. 99 μ^3, MCHC. 34%), and on peripheral smear stipled red cells and Jolly bodies were seen. A random stool sample contained 1,252 Ehrlich units of fecal urobilinogen/100 g. Total serum bilirubin was 2.8 mg/100 ml. with a direct fraction of 0.5 mg/100 ml. The red cell fragility was normal. Bleeding and clotting times, hemoglobin electrophoresis, fetal hemoglobin, plasma hemoglobin, blood urea nitrogen, two-hour post-prandial blood sugar, serum cholesterol, serum glutamic oxalecetic transaminase, serum electrophoresis, prothrombin time, cephalin cholesterol flocculation test, protein-bound iodine, and serum vitamin B$_{12}$ were all within normal limits.

Lupus erythematosus cell preparation, the acid hemolysis test, the direct and indirect Coomb's test, tests for sickle hemoglobin, cryoglobulin, cold agglutinin and serologic test for syphilis were all negative. Stool guaiacs were consistently negative.

Chest x-ray (Figure 1) demonstrated markedly increased central pulmonary vascular markings and decreased peripheral markings. Cardiac cinefluoroscopy confirmed the prominence of the main pulmonary artery as well as the right ventricle, both with increased pulsations. The radiographic picture was not considered compatible with an intracardiac shunt.

Electrocardiogram showed right axis deviation, right ventricular strain, and multiple premature ventricular contractions, the entire pattern being compatible with pulmonary hypertension. Normal mechanics and lung volumes were demonstrated on pulmonary function tests. An oral cholecystogram was normal. Half-life survival of autotransfused Cr^{51}-labeled red cells was only 7.5 days in contrast to the normal half-life of 39 days of tagged normal donor cells.

A bone-marrow aspirate showed increased iron stores, increased siderocytes, and normoblastic hyperplasia. Oscillometric studies revealed markedly reduced peripheral pulsations in all extremities.

The autohemolysis test demonstrated 9.6 to 12.4 per cent spontaneous hemolysis after 48 hours incubation on three different occasions (normal 1.0-3.5). With the addition of glucose the corresponding values ranged from 5.2 to 6.5 (normal range 0.0-0.7). The Heinz body test showed that 73 per cent of the erythrocytes contained five or more inclusion bodies (normal range 0-4). The value for reduced glutathione was 44 mg/100 ml. RBC. (normal range 53-79) and for the glutathione stability test 7.5 mg/100 ml. RBC. (normal range 46-71). The concentration of glucose-6-phosphate dehydrogenase in the erythrocytes was zero (normal range 6.0-8.7 U/100 ml. RBC.) while that of pyruvate kinase was 4.93 U/100 ml. RBC. (normal range 2.0-3.4) and that of acid phosphomonoesterase was 36.2 units (normal range 8.9-35.4).

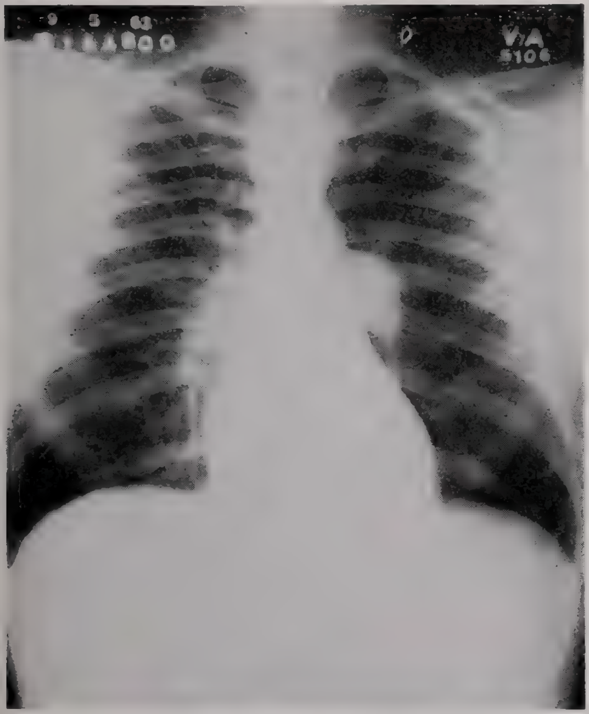

Fig. 1 — PA chest film. Prominent pulmonary artery and main pulmonary artery branches with anemic peripheral vascular markings compatible with pulmonary hypertension.

Treatment and Progress

With bed rest, hot packs, a short course of phenylbutazone, and warfarin sodium there was a rapid and complete clinical clearing of the bilateral superficial phlebitis. Since the persistently high platelet level ($400,000/mm^3$-$900,000/mm^3$) most likely predisposed him to deep vein phlebitis from which he had shed multiple subclinical pulmonary emboli with resultant pulmonary hypertension, it was decided to reduce the platelet count with busulfan. Although it was possible to lower the platelet level to a minimum of $243,000/mm^3$, this was accomplished only at the expense of suppressing the patient's increased hematopoietic activity until the hemoglobin fell to 11.9 g/100 ml. and the wbc. to $3,200/mm^3$; so the drug was discontinued. The patient was discharged on long-term warfarin sodium therapy alone.

Two weeks later he was readmitted. Having forgotten to take his daily dose of warfarin sodium once, the patient took a double dose on the next day. On the following day, while deer hunting, he slipped and fell on his right arm and right flank. Subsequently, until his admission about twenty-four hours later, he developed gradually increasing pain in the right flank radiating into the right groin with darkening of the color of his urine.

Pertinent physical findings on admission included marked right costovertebral angle tenderness without palpable masses. Urinalysis revealed a full field of red cells, but no clots were passed. Prothrombin time on admission was 44 seconds with a control of 12 seconds. His initial hemoglobin was 12.6 g/100 ml., the wbc. $7,550/mm^3$, the platelet count $429,000/mm^3$ and the reticulocyte count 10.6%. An intravenous pyelogram was unremarkable. Treatment consisted of analgesics, cessation of the warfarin sodium and small doses of parenteral vitamin K. On these measures the prothrombin time promptly returned to the normal range and all signs and symptoms of what was considered to be a small renal or perirenal hematoma subsided. Concomitant with this course, however, over a period of five days the patient developed three definite areas of new superficial phlebitis of the lower extremities. Hot packs, phenylbutazone, and intravenous heparin were employed. With clearing of the phlebitis the patient was again discharged on long-term warfarin sodium therapy.

Discussion

Clinical Features

The patient in this report manifests a congenital nonspherocytic hemolytic disease characterized by chronic increased hemolytic activity that was always well-compensated except after two relatively mild febrile illnesses. On at least one of these occasions he apparently experienced a selective bone-marrow arrest of erythropoiesis with severe anemia. Anemia then, though an important part of this disease, is not an invariable one; in many of the cases it is present only intermittently, and was never documented at all in seven of the twenty-seven cases in which it was clarified in the literature (Table 1). As indicated by his history of "yellow eyes" and fatigue periodically through the years, probably the patient reported here suffered many episodes of increased hemolytic activity with jaundice. Jaundice was present in all but two of the twenty-eight cases at some time in their course (Table 1).

On the other hand, it is apparent that many substantial illnesses, for instance all of the childhood exanthemata to which this patient was subject, do not produce significant hemolysis or bone-marrow arrest. It is undoubtedly for this reason that the diagnosis of congenital nonspherocytic hemolytic disease is not one that will be made exclusively in childhood. Of the twenty-six cases in the literature in which the age is given, twelve were diagnosed after the age of thirty (Table 1). The oldest patient in this series, a 59-year-old man, although found to be mildly icteric or anemic on several occasions through the years, apparently required transfusions only once.[20] Splenomegaly was present at some time in thirteen of twenty-three cases where it was described, but only three patients including the present one have had splenectomies (Table 1).

Laboratory Characteristics

The osmotic fragility test was normal and the Cr^{51} red cell half-life substantially reduced in our patient, as was the case in all reports in the literature in which these were elucidated (except for three mild increases in the osmotic fragilities) (Table 1). The enzyme analyses in the patient studied in this report failed to detect any glucose-6-phosphate dehydrogenase, whereas the pyruvate kinase concentration was slightly increased, probably due to the high reticulocyte count. Glutathione was low, the glutathione stability test was abnormal and the Heinz body test was strongly positive. These findings are typical of glucose-6-phosphate dehydrogenase deficiency congenital nonspherocytic hemolytic disease.

Sex-Linked

Since the vast majority of cases of this disease have occurred in males, there can be little question that this is a sex-linked abnormality. A highly variable expressivity in the female heterozygous for this condition has been shown,[14,18-20] some manifesting normal enzyme levels, some borderline low and some markedly deficient values, the latter with mild anemias and increased reticulocyte counts. The three daughters of the patient presented here all had enzyme values well within the normal range, as did his two sons and four of his first cousins. Utilizing the same method, it was not possible to demonstrate any glucose-6-phosphate dehydrogenase activity in the patient's erythrocytes.

Defects in Glycolytic Pathways

It is generally believed that defects in the glycolytic pathway are the cause for the hemolysis in patients with this disease. So far deficiency has been found in glucose-6-phosphate dehydrogenase,[8-21] pyruvate kinase,[28-31] reduced glutathione,[32] glutathione reductase,[33] diphosphoglyceromutase[34] and glyceraldehyde phosphate dehydrogenase.[35] It is only reasonable to believe that there are still others. The first attempt at more detailed studies of these anemias was made by Selwyn and Dacie.[22] Using the autohemolysis test, these workers divided the congenital nonspherocytic hemolytic anemias into two distinct types. Type I showed no or only a moderately increased autohemolysis at 48 hours, with a minor improvement with the addition of glucose. Type II showed a great increase in autohemolysis at 48 hours with no improvement, or even further hemolysis with the addition of glucose.

The patient presented in this report and all six of the other cases of glucose-6-phosphate dehydrogenase deficiency congenital nonspherocytic hemolytic disease on whom the test was performed clearly fit into the Type I of Selwyn and Dacie. It is generally believed that Type I represents glucose-6-phosphate dehydrogenase deficiency and Type II the pyruvate kinase deficiency. Oski

and Diamond,[28] however, have reported that one of ten patients studied with proven pyruvate kinase deficiency anemia did not have the markedly increased autohemolysis characteristic of Type II and three of nine who did have the active hemolysis demonstrated substantial improvement after glucose was added.

Primaquine-sensitive Disease

It has been customary to consider the glucose-6-phosphate dehydrogenase deficiency hemolytic disease as distinctly separate from the primaquine-sensitive type.[1-3,20] The justification for this separation, however, is not altogether convincing. Within the drug-induced group, important differences have been established between Negroes and Caucasians. The incidence of primaquine sensitivity is far greater among Negroes[1-3] than Caucasians except for some select groups of Caucasians, e.g., Greeks, Sardinians, Iranians, and non-Ashkenazic Jews.[36] Marks and Gross[37] have shown that the glucose-6-phosphate dehydrogenase activity of the red cells and white cells of affected whites ranged from unmeasurable to markedly low in contrast to affected Negroes whose red cell enzyme is usually about ten per cent of normal and whose white cell enzyme is normal.

Comparing primaquine-sensitive Caucasians with glucose-6-phosphate dehydrogenase deficiency congenital nonspherocytic hemolytic disease patients, all of whom reported thus far having been Caucasians, sharp distinctions are more difficult to define. The congenital group was thought[1-3,15,20] to be unique in that: (1) its members were completely deficient in enzyme, (2) chronic hemolysis was always present and (3) febrile illnesses were more important than drugs in provoking crises. Analysis of these three factors, however, does not strengthen the case for separation of the groups. For example, measurement of enzyme level alone cannot be considered a conclusive distinction, since some Caucasians of the primaquine-sensitive group have also been reported to have no ascertainable level of enzyme, and even one primaquine-sensitive Negro has met this criterion.[26] On the other hand, Kirkman et al.,[9] in describing five cases of the enzyme-deficiency group with clearly measurable, though distinctly low levels of enzyme, suggest that the reason others have been unable to record levels may be simply a question of methodology, dependent on the stabilizing action of the TPN. and mercaptoethanol on glucose-6-phosphate dehydrogenase.

Red Cell Life-Span

Reduction in the red cell life-span of about 25 percent has been well recognized in a substantial proportion of primaquine-sensitive Negroes[1,7,21] but has been studied little in primaquine-sensitive Caucasians. Recently four patients (Cases 25 to 28 in Table 1) have been reported[21] from non-Ashkenazic Jewish groups known to have a high incidence of primaquine-sensitive glucose-6-phosphate dehydrogenase deficiency. All four with proven enzyme deficiency, when studied under relatively normal circumstances, were found to have well-compensated mild hemolytic processes typical of the congenital nonspherocytic hemolytic disease cases. One of these patients developed two bouts of acute hemolytic anemia after febrile illnesses, as have some others[2] in the primaquine-sensitive group, in the characteristic manner of the congenital nonspherocytic hemolytic disease patients. Two of the others developed comparable bouts after treatment with sulfa drugs. As Ben-Ishay and Izak[21] imply, analysis of these four patients, who could readily fit into either the drug-induced or congenital nonspherocytic hemolytic disease category, lends substantive evidence to the concept that enzyme-deficient congenital nonspherocytic hemolytic disease patients and primaquine-sensitive Caucasians manifest variations of a common theme rather than distinct disease entities.

Qualitative Enzyme Distinctions

In challenging the concept of a quantitative difference in the enzyme deficiency between the primaquine-sensitive and the congenital nonspherocytic hemolytic disease groups, Kirkman and co-workers[9] suggest that distinctions may well lie in qualitative differences in the glucose-6-phosphate dehydrogenase involved. Thus far the most striking difference in the enzymes would appear to be the rapidly lost activity of the enzyme on storage in the congenital nonspherocytic hemolytic disease patients compared to the retention of activity by the primaquine-sensitive individuals. Other differences were also noted. It is dubious that the qualitative differences thus far demonstrated warrant a separation between the two groups, but this would appear a most promising area for further investigation. These same investigators[38] have also been able to demonstrate enzyme distinctions between different ethnic groups of glucose-6-phosphate dehydrogenase deficient Caucasians and suggest that a whole spectrum of clinical variants may be the result of such unique enzyme characteristics.

Acid Phosphomonesterase

Recently Oski, Shahidi and Diamond[26] have shown that acid phosphomonesterase is reduced in Caucasians with enzyme deficiency but not in primaquine-sensitive Negroes. The physiologic significance of this finding is open to question. The patient presented in this report had a normal level of acid phosphomonoesterase, refuting the notion that this is an invariable feature of the disease.

Pathogenesis

The mechanism by which the lowered or altered glucose-6-phosphate dehydrogenase predisposes to hemolysis is still speculative, and several carefully derived theories have been proposed.[2,20,39,40] The crux of these arguments is that in a deficiency state of the enzyme there is impairment of the pentose phosphate shunt, which is dependent on this enzyme. Consequently, reduced amounts of TPNH, the end product of the shunt, are formed. Since TPNH is necessary for the production of reduced glutathione, there are decreased amounts of the latter as well. Reduced glutathione has been shown to be necessary for the maintenance of the red cell integrity in several ways, one of which is to protect the cell membrane from oxidative injury as, for example, by drugs. Mohler and Crockett[19] suggest also that with reduced levels of glucose-6-phosphate dehydrogenase in the red cell there is a corresponding diminution in ATP, and that this may play an important causal role in the hemolysis.

Splenectomy

Since his splenectomy nineteen years earlier, our patient has required no further transfusions. He has, however, a chronic, albeit compensated, hemolytic disease. Because he required transfusion only once prior to splenectomy, it is unlikely that he benefited from the operation. Only two of the other 28 cases in the literature had splenectomy, in neither instance with obvious benefit.[8,9]

Thrombocytosis

The thrombocytosis in our patient is believed to be secondary to the splenectomy. Whereas all surgical operations are associated with elevated platelet counts for transient periods,[41] thrombocytosis after splenectomy is more pronounced and more prolonged.[42,43] It would seem reasonable to postulate that the thrombocytosis in this patient predisposed him to thrombotic complications, which in turn produced multiple subclinical pulmonary emboli or pulmonary thrombosis with resultant pulmonary hypertension. This latter would appear well-documented indirectly by radiographic and electrocardiographic studies. A second possibility, either alone or in combination with the thrombocytosis, that could be conducive to thrombosis and consequent pulmonary hypertension is that of thromboangiitis obliterans (Buerger's disease). The markedly reduced peripheral pulsations in all extremities is compatible with this diagnosis. Although neither of the other two cases with glucose-6-phosphate dehydrogenase deficiency congenital nonspherocytic hemolytic disease with splenectomy has had the extensive follow-up that this patient has had, they apparently did not suffer from prolonged post-splenectomy thrombocytosis and thromboembolism.

Treatment

Busulfan was effective in reducing the

platelet level in our patient; but it also inhibited erythropoiesis and leukopoiesis to such an extent as to necessitate the discontinuance of the drug. Instead, the patient has been given prolonged anticoagulant therapy with warfarin sodium. During the two years he has been on this program he has been symptom-free except for one mild episode of traumatic hematuria on cessation of the anticoagulant therapy.

Summary

1. A case of congenital nonspherocytic hemolytic disease with erythrocyte glucose-6-phosphate dehydrogenase deficiency, the twenty-ninth in the world's literature, is reported. The patient, who has the longest post-splenectomy follow-up of the group, has the additional complications of thrombocytosis with multiple bouts of thrombophlebitis and pulmonary hypertension.

2. Most patients are able to compensate for their chronic hemolytic activity, and only at rare times of erythropoietic arrest or hemolytic crisis demonstrate anemia and jaundice. That these episodes are readily managable is attested to by the fact that almost half the cases were diagnosed after the age of thirty.

3. With the exception of certain isolated groups of Caucasians, erythrocyte glucose-6-phosphate dehydrogenase deficiency is far more prevalent among Negroes. In contrast to the Caucasians, Negroes have normal white cell glucose-6-phosphate dehydrogenase. Clinically, the Negro usually presents with self-limited hemolysis after exposure to one of many drugs, but his Caucasian counterpart in either the primaquine-sensitive or congenital nonspherocytic hemolytic disease group can do the same. More characteristically the latter patient manifests his anemia during the course of a febrile illness. All three groups appear to have a chronic hemolytic process of varying severity. Although the Negro usually has a somewhat higher level and the congenital nonspherocytic hemolytic disease patient is usually essentially devoid of erythrocyte glucose-6-phosphate dehydrogenase, the range of deficiency of erythrocyte enzyme has varied considerably in all. Similarities being as apparent as differences between the groups, especially among the Caucasians, it has been suggested that they may be variants of the same disease rather than wholly distinct entities.

4. In the present case, in contrast to previously reported cases of congenital nonspherocytic hemolytic disease with red cell glucose-6-phosphate dehydrogenase deficiency, erythrocyte acid phosphomonoesterase activity was normal.

Acknowledgment

The authors wish to thank Drs. William N. Valentine, Arthur S. Schneider and George Koutras, University of California Medical Center, Los Angeles, for their part in arranging for and performing the assays of glucose-6-phosphate dehydrogenase, the acid phosphomonoesterase and the pyruvate kinase in our patient.

Some men are not satisfied with the spark of success. They try for an explosion.
— Carey Williams

Green Medicinals

Between Sol and Man there is but one coefficient: the plant life of the globe. Just how one kingdom of the biosphere functions as catalyst between the sun's vital energy and the other kingdom is still one of life's baffling mysteries.

As soon as Dawn Man emerged he began using plants less instinctively and more discriminatingly: first for their nutritive value and later for their therapeutic properties. By an elementary inductive process he determined which simples were effective as antiseptics, emetics, narcotics, purgatives, sedatives, and tonics. Then over centuries of further trial and error implemented by curiosity and necessity Homo sapiens extended his herbal repertory to include such pharmaceutical agents as the anthelmintics (arbor vitae), the carminatives (rose), the cholagogues (mandrake), the emmenagogues (catmint), the galactagogues (anemone), the rubefacients (pine), the tenifuges (fern), and the vulneraries* (tansy).

For did not the Lord adjure Ezekiel: "And by the river upon the bank thereof, on this side and on that side, shall grow all trees . . . and the fruit thereof shall be for meat, and the leaf thereof for medicine."

The Master Word

Though little, the master word looms large in meaning. It is the "open sesame" to every portal, the great equalizer, the philosopher's stone which transmutes all base metal of humanity into gold. The stupid it will make bright, the bright brilliant, and the brilliant steady. To youth it brings hope, to the middle-aged confidence, to the aged repose. It is directly responsible for all advances in medicine during the past 25 years. Not only has it been the touchstone of progress, but it is the measure of success in everyday life. And the master word is work.
—William Osler, M.D.

To Learn the Art

I began the practice of medicine . . . (and) . . . came to this conclusion, which to this day increases in strength, that our art is not to be better learned than by its exercise and use; and that it is likely in every case to prove true, that those who have directed their eye and their mind, the most accurately and diligently to the natural phenomena of disease, will excel in eliciting and applying the true indications of cure.—Thomas Sydenham (1624-1689)

Your Age

Whatever a man's age, he can reduce it several years by putting a bright-colored flower in his buttonhole. — Mark Twain

new

“Doctor, when the kids act up and nothing goes right, I get these throbbing pains in the back of my head.”

a new formulation that relieves pain in tension headache and neuralgia

Dialog is a combination of 15 mg allobarbital and 300 mg acetaminophen. Allobarbital, a proven barbiturate, provides desirable sedation in patients experiencing pain and discomfort. Acetaminophen is a nonsalicylate analgesic-antipyretic, well tolerated and useful in a wide range of mildly painful and febrile conditions.

Dialog is well tolerated, even by those sensitive to aspirin. It is nonirritating to the gastrointestinal tract and has no adverse effects on the kidneys.

- Raises the pain threshold
- Suppresses the pain-producing mechanism
- Reduces emotional tension

2/3453MK—2

Many overweight patients can benefit from the appetite control provided by the sustained anorexigenic-tranquilizing action of BAMADEX SEQUELS: anorexigenic action of amphetamine; tranquilizing action of meprobamate; prolonged action through sustained release of active ingredients.

Bamadex® Sequels®

DEXTRO-AMPHETAMINE SULFATE (15 mg.) SUSTAINED RELEASE CAPSULES
WITH MEPROBAMATE (300 mg.)

to help establish a new dietary pattern

Contraindications: Dextro-amphetamine sulfate: in hyperexcitability and in agitated prepsychotic states. Previous allergic or idiosyncratic reactions to meprobamate.

Precautions: Use with caution in patients hypersensitive to sympathomimetic compounds, who have coronary or cardiovascular disease, or are severely hypertensive.

Dextro-amphetamine sulfate: Excessive use by unstable individuals may result in psychological dependence.

Meprobamate: Careful supervision of dose and amounts prescribed is advised, especially for patients with known propensity for taking excessive quantities of drugs. Excessive and prolonged use in susceptible persons, e.g. alcoholics, former addicts, and other severe psychoneurotics, has been reported to result in dependence on the drug. Where excessive dosage has continued for weeks or months, reduce dosage gradually. Sudden withdrawal may precipitate recurrence of preexisting symptoms such as anxiety, anorexia, or insomnia; or withdrawal reactions such as vomiting, ataxia, tremors, muscle twitching and, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, reduce dosage and avoid operation of motor vehicles, machinery or other activity requiring alertness. Effects of excessive alcohol consumption may be increased by meprobamate. Appropriate caution is recommended with patients prone to excessive drinking. In patients prone to both petit and grand mal epilepsy meprobamate may precipitate grand mal attacks. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side Effects: Overstimulation of the central nervous system, jitteriness and insomnia or drowsiness.

Dextro-amphetamine sulfate: Insomnia, excitability, and increased motor activity are common and ordinarily mild side effects. Confusion, anxiety, aggressiveness, increased libido, and hallucinations have also been observed, especially in mentally ill patients. Rebound fatigue and depression may follow central stimulation. Other effects may include dry mouth, anorexia, nausea, vomiting, diarrhea, and increased cardiovascular reactivity.

Meprobamate: Drowsiness may occur and can be associated with ataxia; the symptom can usually be controlled by decreasing the dose, or by concomitant administration of central stimulants. Allergic or idiosyncratic reactions: maculopapular rash, acute nonthrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever, transient leukopenia. A case of fatal bullous dermatitis, following administration of meprobamate and prednisolone, has been reported. Hypersensitivity has produced fever, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, stomatitis, proctitis (1 case), anaphylaxis, agranulocytosis and thrombocytopenic purpura, and a fatal instance of aplastic anemia, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity, usually after excessive dosage. Impairment of visual accommodation. Massive overdosage may produce drowsiness lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Butazolidin® alka

phenylbutazone, 100 mg.
dried aluminum hydroxide gel, 100 mg.
magnesium trisilicate, 150 mg.
homatropine methylbromide, 1.25 mg.

Usually works within 3 to 4 days in osteoarthritis

The trial period need not exceed 1 week. In contrast, the recommended trial period for indomethacin is *at least 1 month.*

That's why it's logical to start therapy with Butazolidin alka—you'll know quickly whether or not it works. And usually, it will.

A large number of investigators have reported major improvement in about 75% of cases. Some patients have gone into remission. Relief of stiffness and pain may be followed quickly by improved function and resolution of other signs of inflammation. And Butazolidin alka is well tolerated, especially since it contains antacids and an antispasmodic to minimize gastric upset.

Contraindications
Edema; danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. Because of the increased possibility of toxic reactions, the drug should be used with greater care in the elderly and should not be given when the patient is senile or when other potent chemotherapeutic agents are given concurrently. Large doses of Butazolidin alka are contraindicated in patients with glaucoma.

Warning
If coumarin-type anticoagulants are given simultaneously, the physician should watch for excessive increase in prothrombin time. Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea, sulfonamide-type agents and insulin. Patients receiving such concomitant therapy should be carefully observed for this effect.

Use with caution in the first trimester of pregnancy.

Precautions
Before prescribing, the physician should obtain a detailed history and perform a complete physical and laboratory examination, including a blood count. The patient should be kept under close supervision and should be warned to report immediately fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools. Regular blood counts should be made to guard against blood dyscrasias.

Adverse Reactions
The most common adverse reactions are nausea, edema and drug rash. Moderately lowered red cell count may sometimes occur due to hemodilution. The drug has been associated with peptic ulcer and may reactivate a latent peptic ulcer. Infrequently, agranulocytosis, exfoliative dermatitis, Stevens-Johnson syndrome or a generalized allergic reaction may occur and require withdrawal of medication. Stomatitis, salivary gland enlargement, vertigo or languor may occur. Leukemia and leukemoid reactions have been reported but cannot definitely be attributed to the drug. Thrombocytopenic purpura and aplastic anemia are also possibl side effects.

Confusional states, hyperglycemia, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, a have hepatitis, jaundice and several cases o anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently.

Dosage
The initial daily dosage in adults is 300-600 mg. daily in divided doses. In most instances 400 mg. daily is sufficient. When improvemen occurs, dosage should be decreased to the minimum effective level: this should not exceed 400 mg. daily, and is often achieved with only 100-200 mg. daily.

For complete details, please refer to full prescribing information.

Treatment of the Anovulatory Syndrome

ONE OF THE major problems confronting a physician who is interested in reproductive disorders relates to the failure of ovulation. Anovulation is a basic defect in the Stein-Leventhal syndrome,* various disorders of the adrenal gland, pituitary and hypothalamic disorders, nutritional abnormalities including liver disease, hypothyroidism, various psychologic disturbances and dysfunctional bleeding. Therefore the first step towards effective therapy is arriving at an accurate diagnosis, and each patient must be treated according to the etiological factors involved.

Elsewhere in this journal** the "stages of development" of the treatment of the anovulatory syndrome are discussed and the impression is conveyed that all methods tried previous to clomiphene were either unsuccessful or dangerous and should be discarded. Clomiphene may represent the long-sought-for substance capable of inducing ovulation in the human, but at the moment this awaits confirmation. Clomiphene citrate is an experimental drug and available only at certain research centers. Until this medication is released for general use, the practicing physician must continue to rely on less specific methods for induction of ovulation.

There are several general methods that may still be advocated for the production of ovulation. Steroids may trigger pituitary function, or cyclic estrogen and progesterone therapy may completely suppress the pituitary and produce a rebound phenomenon with ovulation when stopped. Intravenous administration of conjugated estrogen has been shown to effectively induce ovulation in nearly half of the patients who fulfill the criteria of adequate proliferative phase activity. The academician points out that there is no justification for administration of thyroid hormone to the euthyroid individual. Yet the clinician has frequently seen cases of irregular, anovulatory bleeding converted to a regular, ovulatory pattern by raising the thyroid function, as measured by the PBI., from the low normal to the high normal range. The close relationship of ovarian function and even low normal thyroid function should not be minimized. Low-dosage irradiation of the ovaries has been proved to be extremely effective in inducing ovulation. Although third and fourth generation follow-up studies have failed to detect genetic abnormalities, this method has been nearly abandoned, because of this potential hazard.

Since all of these methods are readily available, little would be lost by attempting to induce ovulation before referring a patient to a research center.

The ideal patient for clomiphene therapy is one who is anovulatory with adequate

incisive

A good way to describe 'Stelazine'. It's different from the tranquilizers that sedate and dull your anxious patients. Its antianxiety effect is direct. On 'Stelazine', your patients can be calmed yet remain alert.

And 'Stelazine' offers additional benefits. Dependence has not been reported. At low doses, side effects are minimal. Its b.i.d. dosage is convenient and economical.

Stelazine®
brand of **trifluoperazine**

The following is a brief precautionary statement. Before prescribing, the physician should be familiar with the complete prescribing information in SK&F literature or *PDR*. *Contraindications:* Comatose or greatly depressed states due to C.N.S. depressants and in cases of existing blood dyscrasias, bone marrow depression and liver damage. *Precautions:* Use with caution in angina patients and in patients with impaired cardiovascular systems. Antiemetic effect may mask symptoms of other disorders. An additive depressant effect is possible when used with other C.N.S. depressants. Prolonged administration of high doses may result in accumulative effects with severe C.N.S. or vasomotor symptoms. Use in pregnant patients only when necessary for the patient's welfare. *Side Effects:* Occasional cases of mild drowsiness, dizziness, mild skin reactions, dry mouth, insomnia and amenorrhea. Neuromuscular (extrapyramidal) reactions (motor restlessness, dystonias, pseudo-parkinsonism) may occur and, in rare instances, may persist. In addition, muscular weakness, anorexia, rash, lactation, hypotension, and blurred vision have been observed. Blood dyscrasias and cholestatic jaundice have been extremely rare.

For a comprehensive presentation of 'Stelazine' prescribing information and side effects reported with phenothiazine derivatives, please refer to SK&F literature or *PDR*.

Smith Kline & French Laboratories, Philadelphia SK&F

endogenous estrogen but in whom sufficient and cyclic stimulation of pituitary gonadotrophic function is lacking. Best results will be obtained in treating patients with the Stein-Leventhal syndrome, and success can be expected in a high percentage of patients with secondary or hypothalamic amenorrhea. A patient with a reduced estrogen level, such as the one presented by Spellacy and Cohen, will have a less favorable prognosis for subsequent ovulation.

Manifestations of Cancer

THE COMMONEST manifestations of cancer are related to local growth of the tumor which leads to pain, bleeding, or interference with the normal function of organs involved by the primary neoplasm or its metastases.

In its advanced stages cancer becomes a systemic disease as metastases involve diverse systems and as the growth of the tumor interferes with the nutrition of the patient. Apart from these common systemic effects, however, cancer may at times produce symptoms remote from the site of primary or metastatic tumor and not explicable on a simple mechanical basis.

The article of Nuessle in the April* issue of MINNESOTA MEDICINE catalogues these effects. Some, for example, certain of the endocrine disturbances, are clearly related to the synthesis of hormonal substances by the tumor itself. On the other hand, the mechanism responsible for such manifestations as the remote neurological syndromes of cerebellar dysfunction or peripheral neuropathy remains speculative.

Its systemic manifestations may provide an opportunity for early diagnosis of cancer and thus lead to more fruitful therapy. Thus recognition of the significance of hypertrophic osteoarthropaty, acanthosis nigricans, or migratory thrombophlebitis is far from academic. In other instances correct recognition is important as the manifestations themselves may be susceptible to rational symptomatic therapy even if the tumor itself cannot be effectively controlled.

Use of Phenothiazine Compounds During Labor

THE INCESSANT search for medications to induce calmness and cooperativeness during labor as well as to potentiate the pain-relieving actions of narcotics has lead to the widespread use of the phenothiazine compounds.

These compounds have been studied extensively in relationship to their known ability to produce circulatory and respiratory depression, confusion, prolongation of anesthesia, and, under some circumstances, extrapyramidal motor symptoms. From these studies the drugs have been determined to be safe for both the mother and the infant. Drs. Diamond, Tietz, and Spellacy* have contributed further to our knowledge of the safety of one of the phenothiazines, promethazine, by evaluating its potential ability to produce increased levels of serum bilirubin in the infant by its cholestatic mechanism. Their study indicates that promethazine given during labor does not raise the incidence of bilirubinemia in the newborn infant.

In a double-blind study my colleagues and I have evaluated promethazine and hydroxyzine for meperidine potentiation and anxiety relief during labor in approximately 300 patients with term infants. In evaluating the infants three and four days after birth, we found that the incidence of neonatal jaundice was identical in infants of mothers who had received either compound. This study will be reported in detail at a later date. Data from our study, however, indicate that promethazine causes no increase in serum bilirubin levels of infants when given to their mothers during labor.

when agitation

accompanies

spasm of the

'G. I.' tract.

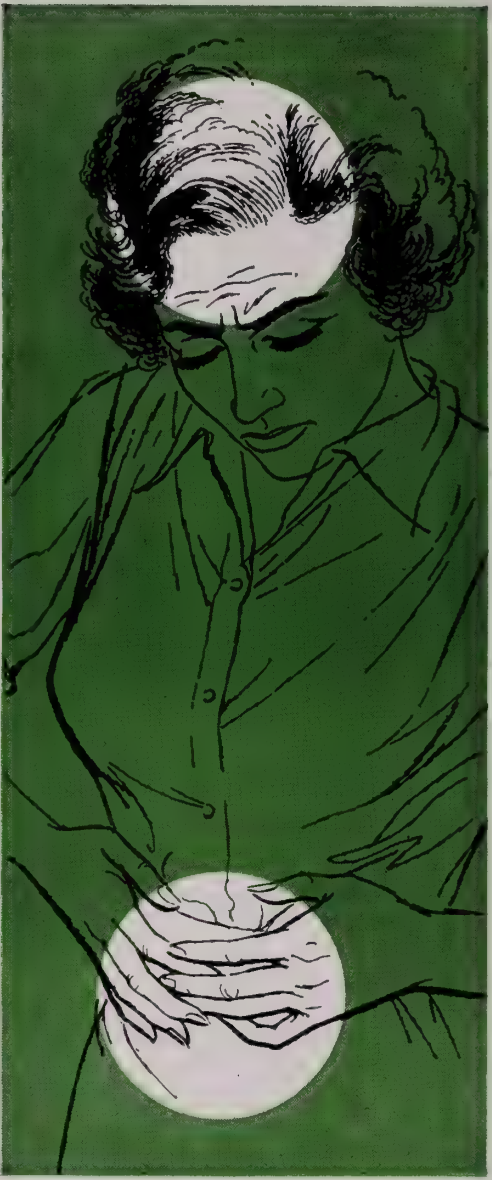
Butadonna(TM)

BUTABARBITAL SODIUM 15 MG (BARBITURIC ACID DERIVATIVE)
WARNING: MAY BE HABIT FORMING
BELLADONNA EXTRACT (TOTAL ALKALOIDS 0.188 MG.) 15 MG

provides gentle,

intermediate sedation and

relaxes 'G. I.' spasm.



Butadonna quiets the "brain-on-gut" influences by providing the smooth, intermediate sedative, butabarbital sodium, desirable in combination with the proven antispasmodic, belladonna extract. Butabarbital sodium is more rapidly eliminated than phenobarbital, and avoids the latter's cumulative effect.

Indications: Antispasmodic-sedative. Useful in the treatment of peptic ulcer, gastritis, duodenitis, irritable colon syndrome, ulcerative colitis, regional enteritis, and other conditions associated with gastrointestinal spasm. Also may be useful in functional dysmenorrhea.

Usual adult dosage is one tablet 3 or 4 times daily as needed.

Caution: Contraindicated in glaucoma and urinary retention. Reduce dosage or discontinue use in event of blurring of vision, dryness of mouth, tachycardia, or excessive drowsiness. Continued use of butabarbital sodium may be habit forming.

The Parathyroid Saga

A THIRTY-EIGHT-YEAR-OLD streetcar conductor started having leg pain in 1921. For five years a host of treatments were attempted, including mercurials for syphilis. Finally, x-rays revealed Von Recklinghausen's disease (osteitis fibrosa cystica generalasata).

In December of 1924 the inevitable happened; the patient broke his leg. Until that time a dialogue had been going on in the endocrinologic world concerning the parathyroid adenomas seen in von Recklinghausen's disease. The generally held view was that these tumors were secondary, a response to demineralization of the skeleton. Further, they were considered a salutary effort on the body's part to compensate for the loss of calcium from the bones. Patients with the disease were treated with quantities of crude animal parathyroid extract. On the basis of the then current theory, Felix Mandl tried an experiment; he transplanted human parathyroid tissue into the patient's neck. There was no improvement. He kept on breaking bones and by July of 1925 had very little skeleton left. Then Mandl reversed his field 180 degrees. He reoperated on his patient's neck and removed a large parathyroid adenoma. The patient got better.

The following is a brief resume of the anatomic, pathologic, and physiologic data that provided Mandl with the impetus to explore the patient's neck. Ivar Sandstrom discovered the parathyroids in 1880. In 1891 von Recklinghausen described his bone disease. In 1896 Vassale and Generali showed that removal of the parathyroids caused tetany. At autopsy in 1903 Askanazy demonstrated a parathyroid tumor in a patient with von Recklinghausen's disease. Next, Jacob Erdheim performed an elegant series of investigations, concluding that calcium is not deposited in the teeth of rats in the absence of parathyroid hormone. From 1907 through 1914 other critical experiments showed that there was parathyroid hypertrophy in rickets as well as in osteomalacia (adult rickets). It had been repeatedly demonstrated that parathyroid adenomas were present in von Recklinghausen's disease, presumably compensatory, like the enlargement of the gland in rickets. The problem turned on the issue of distinguishing osteomalacia from osteitis fibrosa cystica.

All of the above took place in Europe. Meanwhile in America in 1900 Jacques Loeb discovered the role calcium plays in muscle contraction. Hanson and Collip extracted parathyroid principle in 1924. Isadore Greenwald discovered that the Hanson and Collip material puts animals into negative calcium balance. In 1926 Eugene DuBois, studying a certain Captain Martel who kept on breaking bones and passing renal stones, found entirely too much calcium in his blood. The patient was eventually seen by Doctors Albright, Aub and Bauer of The Massachusetts General Hospital. After six operations on the patient's neck, the mediastinum was explored and a tumor removed. Unfortunately the patient never recovered, succumbing to complications of that rather daring procedure for the times.

In the July issue of MINNESOTA MEDICINE Doctors Winter and McQuarrie's report* serves to remind us of the variability in the clinical manifestations of this disease. We are now asked to consider the diagnosis in patients with a variety of gastrointestinal complaints ranging from intractable ulcer disease to chronic relapsing pancreatitis. Thus the story which began in 1880 with the discovery of parathyroids is far from over.

SQUIBB NOTES ON THERAPY

Breast-feeding and the "modern mother"

Despite a mild resurgence of interest in the importance of breast-feeding a few years ago, many women today do not choose to nurse their young. This is for a variety of reasons—social, economic, cultural and sometimes medical. In such cases the physician's task is to find the most suitable means of preventing lactation and easing the pain of breast engorgement.

The means of therapy

The value of hormone therapy for this indication is of course well established. Both androgen and estrogen are known to inhibit the production and secretion of the lactogenic hormone by the anterior pituitary. As estrogen levels decline sharply at parturition, lactogenesis is established. When androgen and estrogen are administered to the patient before the release of the lactogenic hormone lactation and breast engorgement are usually prevented.

The time of therapy

The time of administration of this combined medication is crucial; it must be given early enough to suppress the pituitary prolactin and last long enough to permit physiologic readjustment during the puerperium. Excellent results are most often seen when therapy is administered before the onset of the second stage of labor.

However, factors other than effectiveness must also be considered. The agent selected should not interfere in any way with parturition, subsequent uterine involution and the restoration of normal ovarian cyclic function. Furthermore, it should not cause rebound breast engorgement or other manifestations of hormonal imbalance.

A balanced formulation

Providing single-dose therapy for the prevention of lactation and breast engorgement, Deladumone OB is a potent androgen-estrogen combination with a prolonged action. The optimal balance of androgenic and estrogenic hormones achieved in this preparation minimizes the disadvantages inherent in single hormone therapy, such as rebound breast engorgement. Involution of the uterus and resumption of menstrual cycles are not affected.

As reported in a recent published study (Roser, D. M.: Obstet. & Gynec. *27*:73, 1966), Deladumone OB provided good suppression of breast engorgement in 95.3% and suppression of lactation in 81.1% of 86 obstetrical patients. These results are in general agreement with those of many earlier investigations; in several studies this injectable androgen-estrogen combination proved to be superior to oral medication.

Dosage:

As a single injection of 2 cc. before the onset of the second stage of labor.

Contraindications:

Established or suspected mammary cancer or genital malignancy.

Precautions and Side Effects:

Certain patients may be unusually responsive to either estrogenic or androgenic therapy. In such individuals virilization, uterine bleeding or mastodynia may occur.

Supply:

Deladumone OB, providing 180 mg. testosterone enanthate and 8 mg. estradiol valerate per cc., is available in 2 cc. Unimatic® disposable syringes and in 2 cc. vials. Both preparations are dissolved in sesame oil, with 2% benzyl alcohol as a preservative. *Before use, consult product literature for full prescribing information.*

Deladumone® OB

Squibb Testosterone Enanthate (180 mg./cc.) and Estradiol Valerate (8 mg./cc.)

Single-dose injection for lactation inhibition

SQUIBB *'The Priceless Ingredient' of every product is the honor and integrity of its maker.*

Intraspinal Arteriovenous Anomalies

In the February issue* of Minnesota Medicine a preliminary report appears on the surgical treatment of intraspinal arteriovenous anomalies.

Although arteriovenous malformations of the spinal cord are rare when contrasted with their occurrence in the brain, the condition can be diagnostically perplexing. The sites in the spinal cord that are most often affected are found to be the lower thoracic to the upper lumbar segments and the cervical enlargement.

These malformations may bleed spontaneously or rupture with trauma, resulting in bleeding into the subarachnoid space or into the substance of the cord. They may be confused with subarachnoid bleeding from an intracranial source, but can usually be differentiated by evidence of spinal cord involvement. When bleeding takes place within the cord, there is an abrupt onset of symptoms with intense pain in the back followed shortly by a flaccid paralysis and loss of sensation below the level of the lesion.

Other symptoms may arise from compression of cord structures or by thrombosis leading to ischemia or infarction of the adjacent cord parenchyma. This latter event may, of course, occur episodically, leading the diagnostician to consider a demyelinating disease such as multiple sclerosis because of the relapsing nature of the symptoms.

Too often this condition cannot be differentiated from other processes leading to progressive spinal cord symptomatology until myelography is carried out revealing a pulsatile, tortuous mass extending over many cord segments. Aortography can better delineate the malformation, provided that the feeding blood vessels are of a size sufficient to be visualized radiographically.

Earlier reports about the benefits of the surgical treatment of such lesions have been pessimistic. This pessimism arose from the knowledge that these vascular malformations usually lie within the cord as well as upon its surface and that the blood supply to the spinal cord is a tenuous one.

The anterior spinal artery is throughout much of the length of the spinal cord a slender longitudinal chain of anastomosing vessels formed by ascending and descending radicular arteries. At the thoracic segments Tl-4 and the first lumbar cord segment the anastomoses are meager, leaving these areas especially vulnerable to any interference with their vascular supply. Arteriovenous malformations are capable of altering the normal hemodynamics of an area by their shunting of arterial blood directly into the venous system, thereby depriving the tissue of its normal blood supply. Under these circumstances one wonders if further damage to the cord parenchyma may not occur following the ligation of the arterial feeders to the malformation.

Hepatolobectomy for Metastatic Malignancy

Hepatolobectomy for metastatic malignancy is a controversial subject, to say the least. The opportunity to make such an operative decision is not likely to present itself even once a year to most surgeons.

In the case of the four-year-old boy with metastatic neuroblastoma, Drs. Brown and Hart* have given a clear and concise, yet detailed account of a complicated problem and also an excellent description of the operational procedure. While the outcome was disappointing, many lessons can be learned from a study of the report.

Neuroblastoma is one of the most unpre-

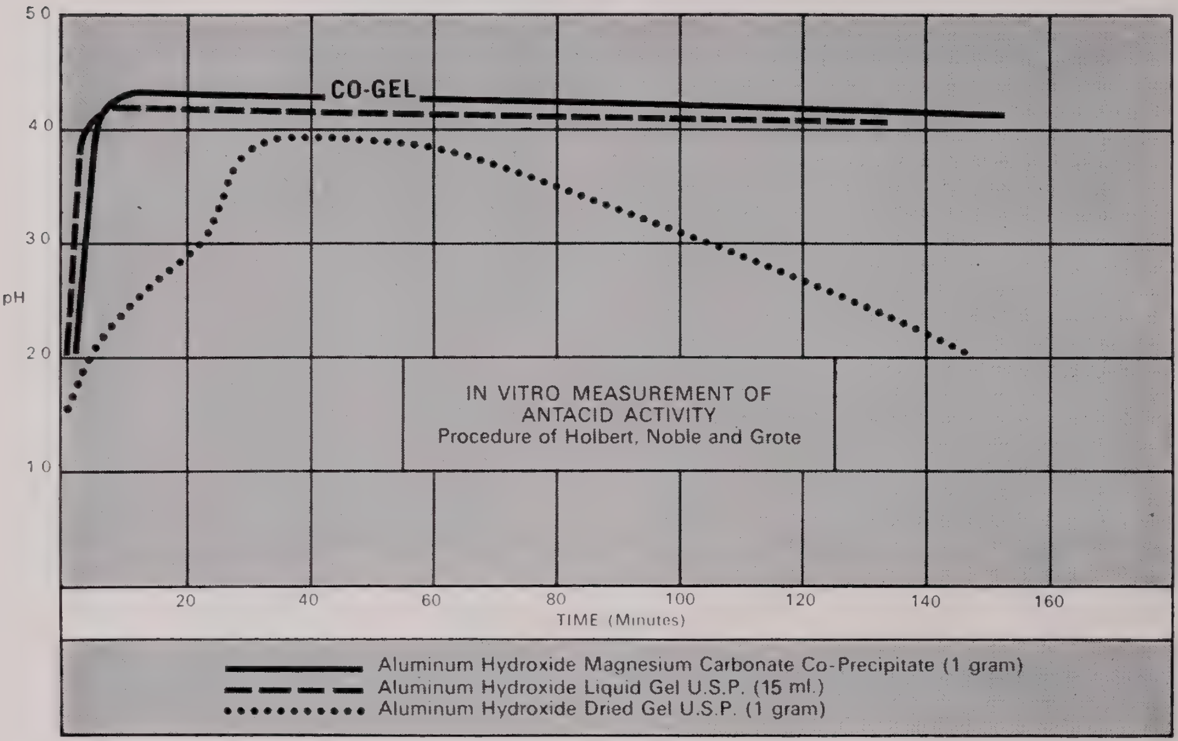
CO-GEL

THE NEW ANTACID



Holbert, J. M., Noble, N., and Grote, I. W.—Jnl. Amer. Pharm. Assoc. (Sci. Ed.) 37,292 (1948).

Now, an antacid tablet with the effectiveness of a liquid!

CO-GEL is not just another antacid, but rather it's an entirely *new antacid compound* for gastritis, hyperacidity and peptic ulcers. It is an Aluminum Hydroxide formulation with Magnesium Carbonate Co-Precipitate. The Co-Precipitate, a new chemical, gives CO-GEL Tablets the speed of action and the duration of a liquid antacid.

The above chart compares the antacid action of the COGEL Tablet formula with both liquid and dry $Al(OH)_3$. Notice that CO-GEL neutralizes acid faster than $Al(OH)_3$ dried gel tablets and has a prolonged buffering action. The CO-GEL curve parallels that of liquid $Al(OH)_3$.

Liquid CO-GEL, containing the Co-Precipitate, is also available. CO-GEL is reasonably priced to the patient. Availability: CO-GEL Tablets (bottles of 100 and 1,000) CO-GEL Liquid (pints and gallons).

For complete information and samples, write to Dept. MM-105.

FORMULA

Each CO-GEL Tablet, and teaspoonful of CO-GEL Liquid, contains 330 mg. of Aluminum Hydroxide Magnesium Carbonate Co-Precipitate. Tablets have a chewable base. Both forms are mint flavored.

CONTRAINDICATIONS

None.

DOSAGE

For relief of hyperacidity, peptic ulcers or gastritis, chew one tablet (or take one teaspoonful). Repeat in 1 hr. if necessary.

dictable of malignant lesions. Many instances of cure have been reported after only limited operative manipulations ranging from simple biopsy to an unsuccessful attempt at total removal. In other cases the apparent cure has been attributed to x-ray therapy, to chemotherapy with agents as innocuous as vitamin B_{12}, or to both methods.

Metastasis to the liver and other viscera has been known to disappear completely under various forms of therapy or, surprisingly, even in the absence of therapy. Skeletal metastatic lesions, however, have been much less accommodating.

It is this unpredictability of neuroblastoma which gives hope to both patients and physicians and encourages such a strenuous undertaking as hepatolobectomy.

Much has been written about the beneficial effects of preoperative irradiation. Temporary reduction in size is an obvious and measurable result in most cases. The implication usually has been that such irradiation makes the surgeon's task much easier. In my own experience with preoperative irradiation, the difficulties often seem greater than usual, due to bleeding, adhesions, and a tumor which is partially necrotic and friable, and often disintegrates on manipulation. Thus, preoperative irradiation invariably leads to speculation as to what effect delay, therapy, and extra manipulations and examinations may have on the spread of the first malignant cells.

For me, one unmentioned value of preoperative irradiation has been a sense of aggressive confidence, knowing the family is emotionally prepared for a strenuous attack on an often hopeless problem. Only rarely does a patient receive irradiation without conclusive and confirmed diagnosis. Consequently, the family is emotionally prepared much the same as they are prepared for a "second look" or "redo" operation. This emotional adjustment is rarely present with the exploration for "suspected" malignancy; consequently the operative measures are possibly less heroic than in the other situations mentioned.

The transplantation of hepatic tissue is now mechanically feasible, and only the mysteries of host rejection still seem to hinder successful substitution. Since the liver functions so well even when massively replaced with malignant tumor, successful transplantation will more likely be considered in cases in which the liver has been destroyed by infection or benign tumor processes. Reports are now appearing of attempts to remove a portion of a widely disseminated malignant tumor and reimplant it in the host after various treatments outside the body. Although it is too early to be optimistic, there is hope.

The whole philosophy of the management of malignant lesions in children is changing. Certainly palliation must be viewed differently in a four-year-old child than in a 64-year-old adult. In a four-year-old patient the primary objective is obviously complete cure; failing this, palliation is directed only toward relieving pain and comforting the parents. Once it becomes obvious to all concerned that cure is no longer possible, any treatment which merely prolongs life or elevates the level of consciousness seems unjustified. Fortunately, each day brings some new glimmer of hope for the otherwise hopeless problems. Malignant lesions of many types are showing sufficient response to chemical agents to be encouraging. The plight of a four-year-old suffering from uncontrollable diabetes mellitus probably appeared just as hopeless in 1920 as does that of the four-year-old with a metastatic malignancy today.

Since hope springs eternal in the hearts of parents, it is our obligation to do everything humanly possible to restore health. Once the case is terminal, we are equally obliged to see that death is not robbed of its dignity.

Amputation of Lower Extremity

THE DECISIONS when and at what level to amputate the lower extremity are of equal importance. It is desirable to save all viable tissue; however, the best level for efficiency of a prosthesis demands consideration. The degree of trauma frequently determines the level. When to operate may be an even more serious immediate problem.

(A) I recall a news report in a San Antonio paper that an airplane had crashed and that the pilot was so badly injured that a bilateral thigh amputation was performed. I made the statement at the time that the next day's paper would state that the pilot did not survive his surgery—and it did.

(B) A patient's family demanded that I see an elderly gentleman on the way to the operating room for amputation of a traumatically injured leg. The patient was in shock with a blood pressure of 50. A tourniquet was applied immediately above the injury, and the distal extremity encased in dressings saturated with 10 per cent formaldehyde solution. He received urgent immediate shock treatment and blood replacement. Several days later when he was in good condition the leg was amputated uneventfully at the level of the upper border of the tourniquet.

The temporary tourniquet procedure is reported to have been employed by the Chinese many years ago where soldiers could not receive surgical attention for days and required many miles of transportation.

My first experience with the temporary tourniquet amputation was when I was assistant to Dr. R. E. Farr. A young man was in a very critical condition due to gas gangrene infection superimposed on an extensive arm injury. The same procedure was employed. Gangrene did not advance above the tourniquet. An amputation was performed uneventfully a week later.

The level of amputation in patients with endarteritis obliterans may present a problem. We have seen patients who first had a toe removed, later a calf amputation, and finally an amputation at a viable level.

If an occluding embolus is present and is not removed, pulseless vessels and discoloration soon reveal the level of viability.

The aged patient with obstructing arteriosclerosis, with diabetes, or coronary disease presents a challenge. Amputation and reamputation are not uncommon. Failure of an operation below the knee leads to additional hazard if a thigh amputation becomes necessary.

During more than 50 years in the training for surgery and its practice I have had an unusual experience with amputation, based on my use of the temporary tourniquet procedure together with my use of local anesthesia in very hazardous cases.

The methods which Dr. Henry Wessman* described to determine the adequacy of the circulation of a lower extremity with regard for the vascular efficiency can be of great value in pathological arterial obstruction.

When to operate and at what level to amputate demand necessary consultation, experience, and above all good surgical judgement.

Stanley R. Maxeiner, Sr., M.D.
Minneapolis, Minnesota

Importance of Prompt Correction of Anemia in Infants*

THE IMPORTANCE OF prompt correction of anemia as severe as noted in this case is emphasized by the fact that true heart failure developed. The cautious administration of packed erythrocytes might have averted the failure, because this would have given effective cells to carry much-needed oxygen. The increasing size of the liver is the most striking evidence for cardiac failure, as it

appeared in this case or might appear during the administration of packed erythrocytes. Although it is generally believed that digitalis is of little benefit in congestive heart failure accompanied by severe anemia, Fowler et al.[1] showed that it is effective.

The one striking factor in the causation of anemia in this child was an inadequate dietary intake of protein and iron. The weight gain was not excessive, the mother was not anemic, and there was no apparent blood loss in the stools. Ferrous sulfate is indeed the most effective form of treatment; although other ferrous preparations may be more palatable, they are not so effective. One can consider intramuscular injection of iron in cases of severe anemia, a type of treatment that gives a more prompt increase in the hemoglobin concentration and, if the anemia is not so severe that cardiac failure is a threat, might eliminate the need for transfusions.

Anemia of this degree can be avoided if one is especially alert for it in premature infants or in children from mothers who are anemic or who have had multiple pregnancies; particularly, the problem of excessive milk intake should be kept in mind. As the infant approaches five to six months of age, iron-containing foods should be included in the diet (cereal, egg yolk, and meat). Then as the child approaches eight to 10 months of age, weaning it from the bottle to the cup will promote a greater intake of meat, vegetables, and other foods which contain a higher percentage of iron.

The Editor's Soliloquy

The Human Paradox

We love the individual but we hate the group. We trust our friend but we are skeptical of his. We can always find an isolated exception to disprove the rule while we often question the validity of overwhelming evidence.

En masse, the plumber, the carpenter, the mechanic et al. are bunglers and charlatans, whose charges are exorbitant for a twist of a mere screw and who 'discover' things to repair that we never even knew existed; whereas the architect who designed our particular house or the engineer who devised our favorite car must have been a paragon of ingenuity; else how could the house have stood up so sturdily or the car have functioned so smoothly for so long!

In the opinion of the layman even doctors fall collectively into the category of a suspect group. Each physician of us singly is a dedicated humanitarian; in the aggregate we constitute a coldly calculating and venal fraternity.

No one who knows me, the individual doctor, hates me; but many hate the medical profession in general. They resent our steady nerve but endorse our courage in a crisis; they laud our integrity but deprecate our refusal to compromise by so much as an iota.

They praise our meticulous office and the bevy of nurses who keep it spotless; but they criticise the fees required for the purpose. They are humbly flattered to be attended to without a nickel in their pockets; but they airily ignore the month-after-month statement that arrives and too often remains in the windowed envelope to augment their pile of unpaid bills.

They return to the doctor who prescribes a self-perpetuating list of ineffectual remedies but go elsewhere if he points out that a physiologic process must run its inexorable course. They beam on the doctor who agrees that their massive overweight is 'just right' but accuse him of having no understanding of their energy requirements if he suggests that they would feel better trimmed down.

They are 'forever grateful' to the doctor who 'pulled them through' a complicated postoperative convalescence; but they are nettled for having been dismissed from the hospital on the third postoperative day. They appreciate his generosity if he keeps them on compensation for a few weeks beyond the recovery period but consider him heartless if he recommends work as the best physiotherapy.

All in all, as hostages to fortune from birth to death, they find us doctors indispensable and irreplaceable; but they wish they didn't.

So it goes with the human species vis-a-vis its doctors and other professional, political, economic, and social brotherhoods. The so-called lower animals are distinguished for their simplicity, consistency, and directness. Why must mankind alone be devious, oblique, and perverse? Why must paradox be the hallmark of Homo sapiens?

If you can figure it out let me hear from you. I'll be waiting!

Carl O. Rice, M.D.

Mom says: A "blueblood" is nothing more than a man with a lot of "greenback."
— C. O. R.

The population explosion

Chomp. Chomp. Chomp. He's off again on another spree of second helpings.

Tomorrow, crash! He'll be on a newfangled diet. Starving himself.

He's just one of the many who bounce between starvation and overeating, and with every rebound make losing weight more difficult.

As a professional, you can help. First by pointing out that skipping meals is no solution, and second by recommending long-range weight control through sensible eating habits and nourishing foods. Every day. Day after day.

Naturally, balanced diets and nourishing, palatable dairy foods go together; they always have.

Project Weight Watch has been initiated to assist you. Its scope is nationwide, its purpose is to focus professional attention on the problem.

To help you translate your concern to your patients, a portfolio of materials is available. Send for it. Support girth control.

Curbstone Consultation

QUESTION: What triad of laboratory tests can be ordered to assist in diagnosing pulmonary embolism and infarction, and differentiating them from pneumonia and acute myocardial infarction?

ANSWER: Patients with pulmonary embolism or infarction usually have an elevated serum lactic dehydrogenase (LDH) and serum bilirubin, but their serum glutamic oxaloacetic transaminase (SGOT) remains normal. This combination tends not to occur with pneumonia and acute myocardial infarction.

QUESTION: What common chemical tests must be done fasting?

ANSWER: a. Serum phosphorus. b. Serum cholesterol.

Mammograms

QUESTION: If a mass is palpable in the breast, should a negative mammogram be relied upon as evidence that cancer does not exist?

ANSWER: Mammography is a useful adjunct in the diagnosis of breast carcinoma but it will not take the place of an adequate history and physical examination. Regardless of the interpretation of the mammogram a persistent discrete nodule in the breast should be biopsied and the definitive treatment based on the histopathology. Radical mastectomy should never be performed on the basis of the roentgenologist's report without histological confirmation of cancer.

Biopsies should be performed, however, when the mammogram suggests a lesion, although the nodule cannot be felt. When such a biopsy is taken, the advice of the roentgenologist should be sought to determine the exact location of the lesion. Frequently the lesion is so small relative to the surrounding breast tissue that the tumor can be easily missed. In such cases, a fairly large section of the breast must be removed to be sure of obtaining the right area for diagnosis.

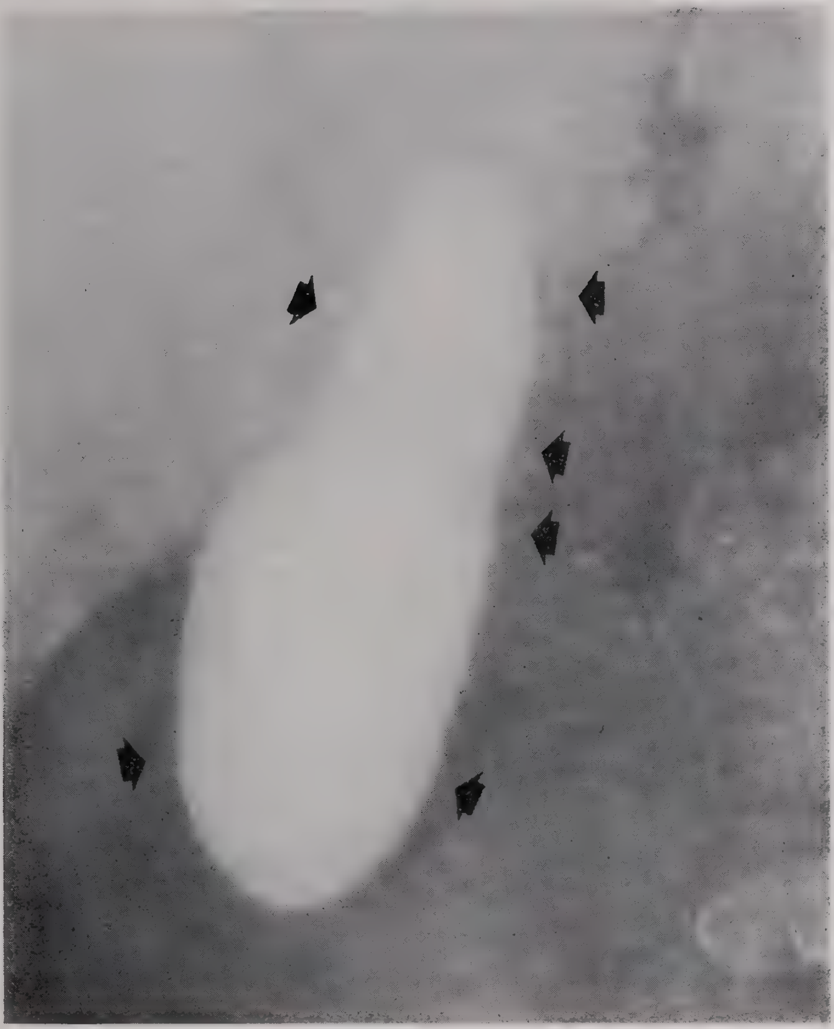
The Viewing Box



A 37-YEAR-OLD, moderately obese, parous, white female presented at The Duluth Clinic with epigastric and right upper quadrant pain of two days duration. The pain was characterized as cramping in nature and was associated with slight nausea. She had a history, during the past four years, of recurrent episodes of mild epigastric and right upper quadrant distress complicated on occasion with intolerance to fatty food. Symptomatology responded with the usual antispasmodics, antacid and dietary programs. There was no weight loss. Abdominal examination was unremarkable; there was no icterus and laboratory studies were within normal limits. It is of particular interest that an oral cholecystogram obtained four years previously, in 1960, revealed excellent concentration of dye, no calculi, but finely serrated margins suggesting the possibility of cholesterosis. An upper G.I. examination and an excretory urogram were unremarkable at the time of the present admission.

The oral cholecystogram routinely includes the post fatty-meal film which reveals multiple sinuses (arrows in Figure 1) extending from the lumen of the fundus into the wall of the gall bladder.

What is your diagnosis?

DIAGNOSIS:

Adenomyomatosis of the gallbladder (intramural diverticulosis)

Adenomyomatosis of the gallbladder is a benign hyperplastic condition involving the epithelium and muscular layer of the gallbladder. There is proliferation with deep branching penetration of the Rokintansky-Aschoff sinuses. Occasionally small papillomatous intraluminal proliferations are also seen. The muscle layer is usually thickened, sometimes grossly, and it is felt that the plexiform arrangement of the muscle bundles facilitates the passage of epithelial expansions. There can be excessive fibrous tissue in the wall.

Radiographic demonstration of dilated sinuses is possible when they are fairly large and other conditions are suitable; e.g., concentration must be good, the neck of the sinuses not occluded and the sinuses not obstructed with stones or bile pigments. These distended sinuses will usually be seen best after the gallbladder has contracted in response to a fatty meal, frequently after one-half hour. However they are sometimes better demonstrated after one or one and one-half hours when the gallbladder has contracted further. We have found laminography, though not essential, very helpful. As in this case, they appear as bead-like structures forming a rim around the gallbladder or they may appear as a cluster at the site of a stricture or of the fundus. Pathologists can aid in confirming the diagnosis if the gallbladder is handled with care at surgery and if the formalin-filled gallbladder is placed in a receptacle containing formalin. This permits the pathologist a greater choice of staining technique.

The condition may be suspected on oral cholecystography when persistent angulation of the gallbladder is found and the wall thickened. Thus, any gallbladder exhibiting strictures, septa, kinks, angular deformities or irregularities of outline should be suspected. Often careful studies of such cases will reveal dilated sinuses. Similarly, gallbladders which concentrate and contract better than usual yet contain calculi should be closely scrutinized.

Frequently symptoms are vague, consisting of epigastric and right hypochondriacal post-prandial discomfort. However, symptomatology may be similar to that of cholecystitis and cholelithiasis. Jutras described three conditions, cholesterosis, adenomyomatosis, and neuromatosis, which frequently co-exist under the term "hyperplastic cholecystosis," and felt that a combination of these conditions would induce excessive gallbladder contraction and hence a hyperfunctional syndrome causing severe lasting pain, intermittent colic and indigestion, biliary dyspepsia and even "psychosomatic" distress.

It seems most likely that adenomyomatosis is essentially a degenerative process associated with aging. It has been pointed out that adenomyomatosis of the gallbladder and diverticulosis of the colon are analogous not only in distribution and morphology of the pockets but also in the intervening structures. To this may be added the fact that both conditions can co-exist in the same individual, a phenomenon that increases with age. However, work with laboratory animals has shown that prolonged administration of estrogens and other steroids may induce fibromyomata of the uteri and adenomyomatosis of the gallbladder. Colquhoun states that this condition is thought to predispose to stone formation and cholecystitis but may be found without either.

It is of interest in this patient that more severe symptoms recurred one year after this study and an oral cholecystogram at that time revealed a thin layer of dense small radiolucent calculi. At surgery the lumen contained innumerable, very minute calculi averaging about one mm. in diameter or less. It is of particular interest that this patient was thought to have hypermenorrhea on the basis of adenomyosis of the corpus uteri, yet another condition morphologically similar to adenomyomatosis of the gallbladder.

Medical Women on Postage Stamps

Florence Nightingale (1820-1910) was an English war nurse and hospital reformer, who with 37 nurses served in the Crimean War (1854) and who received the Order of Merit (1907). As The Lady with the Lamp she received recognition on postage stamp issues in several countries — among them Belgium (1939), Costa Rica (with Edith Cavell, 1945), Germany (1955), and Nationalist China (1964).

Clara Maas (1879-1901) was a U. S. army nurse who worked with Gorgas combatting yellow fever in Cuba and who, for the cause, allowed herself to be fatally bitten by a mosquito. A Clara Louise Maas and Hospitals postage stamp issued in Cuba in 1951 commemorates her martyrdom.

A Case of Hypo*

"One of the worst cases of hypo recorded was that of an old urine doctor who, feeling bad, set aside a specimen to be examined after it had settled. While he was out of the office a woman who imagined from circumstances that she was in a state of pregnancy decided this would be a good time to find out. She therefore discharged the phial of its contents, and filled it up with her own water. — When the doctor returned (not suspecting any thing of what had transpired), his consternation was inexpressible to find from the appearance of the urine that he was in a state of pregnancy, and realized from the organization and structure of his system that he saw no chance of delivery. He became almost frantic at the discovery, and nothing saved him absolute despair but the discovery of the real facts as they transpired."**

Soyalac
SOLVES THE PROBLEM

for the infant who requires a milk-free diet!

Loma Linda
Soyalac
CONCENTRATED
LIQUID
Hypoallergenic
For Infants Children and Adults
Loma Linda Foods

- Soyalac satisfies! Baby is happy, mother is grateful, doctor is gratified.
- The nut-like taste is pleasing. Infants readily accept this hypoallergenic formula that is completely fibre-free. An exclusive process results in a consistency much like milk.
- Soyalac is strikingly similar to mother's milk in composition and ease of assimilation. Clinical data furnish evidence of Soyalac's value in promoting normal growth and development.
- Excellent for regular infant feeding, too—and for growing children and adults.

Fracture–Trauma Conference

Partially Healed Mandibular Fracture

A 17-YEAR-OLD girl was involved in a two vehicle automobile accident. As a result, she sustained a severe head injury as well as a fracture of the anterior mandible and fractures of the shoulder girdle.

A tracheotomy had been performed shortly after the accident, and she was given general care in her local community. She remained unconscious for about one week and was transferred by a Minneapolis

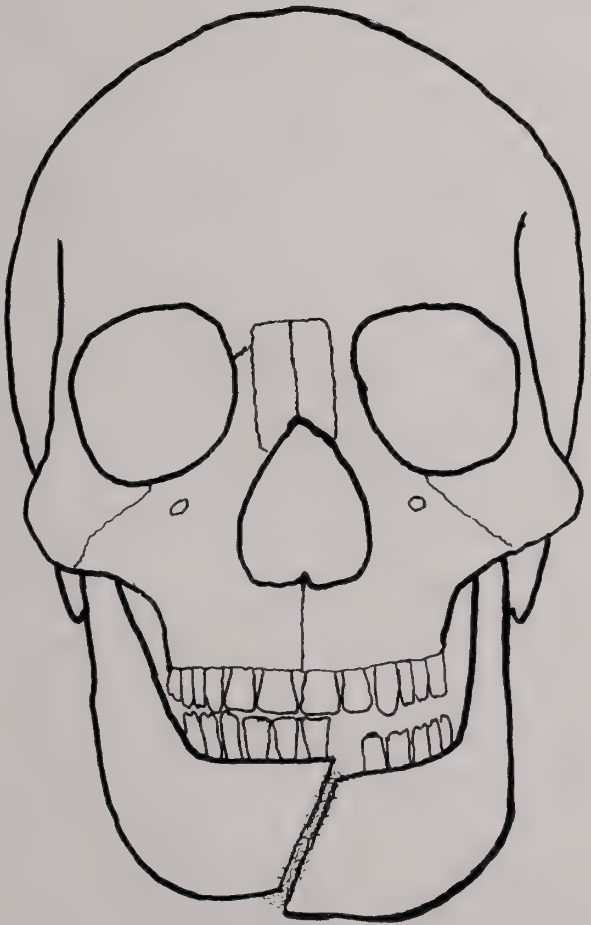

Fig. 1 — Anterior mandibular fracture with displacement of the left fragment about 1 cm. inferiorly. There is nearly firm healing at the fracture site and the patient is unable to close left side of dental arch.

Continued

hospital 19 days after the accident. At this time there was definite malocclusion of the teeth.

Facial Bone Examination

The patient was still not clear mentally. There was an oblique fracture in the anterior mandible with the left fragment overriding the right fragment by about 1 cm. (Figure 1). A palpable deformity was present along the lower border of the mandible, and there was marked malocclusion of the left side of the dental arch. The left mandibular fragment, in addition to being displaced inferiorly, was also rotated lingually. At the fracture site almost complete healing had occurred, so that only slight motion could be elicited. A well functioning tracheotomy tube was in place.

Surgical Correction

Twenty-four days after the accident, the fracture site in the anterior mandible was exposed through an incision at the lower border of the chin. There was considerable callus and fibrous fixation in the fracture site. The area of fibrous union was broken down with a periosteal elevator and the fragments reduced to correct position. Drill holes were placed in the lower mandible (below incisor roots), and the two fragments were held in correct position with a #24 stainless steel ligature through the drill holes (Figure 2). The skin wound was closed in layers.

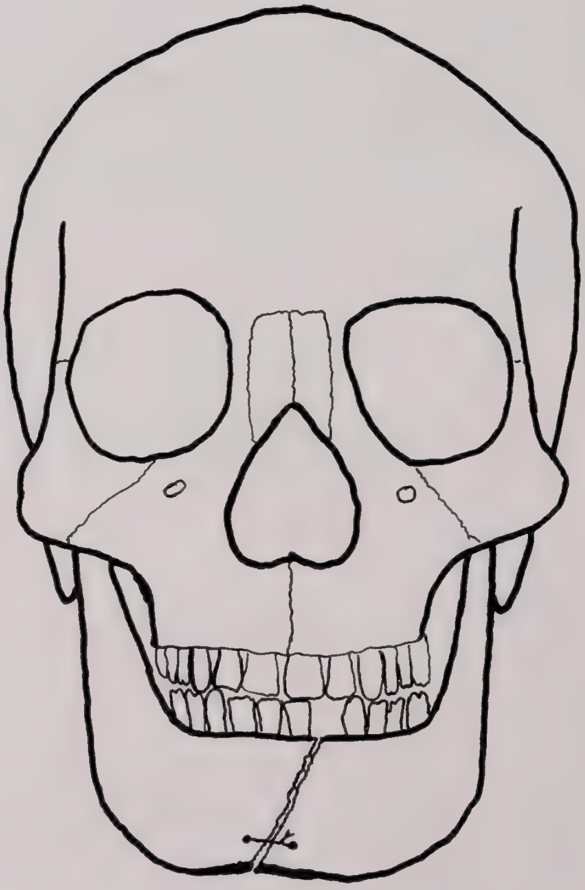

Fig. 2 — Fracture site exposed through incision at the lower border of chin. The area of fibrous union and callus was broken down and the fragments held in corrected position with interosseous stainless steel ligature. Intermaxillary approximation of teeth by use of Erich arch bars and elastic bands was also employed.

Erich arch bars were then ligated to the teeth in the upper jaw and to the teeth in the two lower jaw fragments. The dental arches were held in correct occlusion with elastic bands between the arch bar hooks. The postoperative course was uneventful; dental fixation appliances were removed five weeks later and the jaw was well healed with dental occlusion as before the accident.

Comment

Healing of fractures of facial bones (as in the extremities) in children and adolescents is usually quite rapid. In the case presented, because of the severe head injury, there had been a delay in the management of the mandibular fracture until about three weeks following the accident. Rapid healing in this young person had resulted in nearly firm healing of the fracture but in poor position. Intermaxillary traction alone at this date would not have corrected the deformity.

Reduction of the fragments to normal position was accomplished by breaking down the area of fibrous union and holding the fragments in corrected position with an interosseous wire ligature. Intermaxillary elastic traction with Erich arch bars was also employed. Healing of the jaw in good position with normal occlusion was obtained.

The management of a partially healed mandibular fracture is presented.

The Hindu Trimurti

As familiar as Father, Son, and Holy Ghost to a Christian are Brahma, Vishnu, and Siva to a Hindu. This triad consists of Creator, Preserver, and Destroyer. In the operation of cosmic law these three powers are total; Brahma creates the World; Vishnu preserves it as long as it merits preservation; when it inevitably retrogresses, Siva destroys it. But though Siva is the destroyer, he contains within himself the seeds of regeneration for a new and better world — to be created in turn by Brahma, thus completing one cycle and initiating another in the universal evolutionary ascent.

While the esoteric aspects of Hindu cosmogony and cosmology may seem alien to our more materialistic Western minds, we might well ask ourselves in our complacency: Can we Occidentals profit in any way from the Oriental theology? For example, reflecting on the role of Vishnu, are we wise conservers? Under the pressure of 'Progress' are we too fanatically eager to discard the old for the new? Do we repudiate and abandon what still has utility and validity within the framework of our social system? Or, on the other hand, do we make a fetish of the status quo? Do we continue practices and maintain institutions long after they have become obsolete or corrupt?

These are questions that might well give us pause.

Persons who are naturally very fat are apt to die earlier than those who are slender.
— Hippocrates

MOLECULAR REMODELING—

laboratory exercise or clinical necessity?

More than twenty-five years have passed since the discovery of the diuretic activity of sulfanilamide started pharmacologists on a succession of molecular remodelings to find the ideal diuretic.

Diuresis—a sought-after clinical effect from an unwanted side effect

It started in 1937 when a clinician reported that the administration of a sulfonamide was sometimes accompanied by an unexplainable side effect—metabolic acidosis.[1] Three years later the side effect was explained. The sulfonamide radical of sulfanilamide inhibited carbonic anhydrase,[2] the enzyme responsible for converting carbon dioxide and water to hydrogen ions and bicarbonate ions.

Later, other investigators showed by dog experiments that metabolic acidosis probably resulted when the inhibition of carbonic anhydrase upset the exchange of hydrogen and sodium ions, causing increased excretion of sodium as the bicarbonate.[3]

It was twelve long years after the first report of the unexplainable side effect (metabolic acidosis) that it was finally shown that large doses of sulfanilamide administered to edematous patients were indeed capable of promoting diuresis.[4] However, the possibility of toxic effects from its prolonged use and its relatively weak diuretic action made it impractical for clinical use as a diuretic.[5]

Because the inhibition of carbonic anhydrase seemed to be the key to effective diuresis, investigators began to look for more potent enzyme inhibitors —in the hopes that they would be more effective diuretics.

The most important of these early compounds, acetazolamide, enjoyed several years of fairly wide clinical use.

Its carbonic anhydrase inhibitory activity was several hundred times greater than that of sulfanilamide.[6] The increase in inhibitory activity, however, increased not only the excretion of sodium and bicarbonate ions, but also the excretion of potassium.[7] And, like its predecessor, acetazolamide precipitated mild acidosis. Its prolonged use could result in hypokalemic acidosis.[7]

The 'thiazides'—an answer to the metabolic acidosis caused by carbonic anhydrase inhibition

Despite the fact that the sulfonamide group appeared to be responsible for carbonic anhydrase inhibition which in turn appeared to be responsible for diuresis, investigators began to synthesize compounds with structural alterations to the sulfonamide group.

The first major breakthrough came with the synthesis of chlorothiazide. Altering the sulfonamide group did indeed alter the ability of chlorothiazide to inhibit carbonic anhydrase—it was only 1/10th as potent as acetazolamide in inhibiting the enzyme.[8] Despite the drop in inhibitory potency, however, chlorothiazide proved to be an effective diuretic—an observation that led to the conclusion that its diuretic action was due to some mechanism other than its action on carbonic anhydrase.[9, 10]

For effective diuresis, chlorothiazide was administered in daily dosages ranging from 250 to 2000 mg.[11] It increased the excretion of sodium and chloride; and, to a lesser extent, potassium and bicarbonate.[11] The excretion of potassium appeared to be maximal at higher dose levels at which, theoretically, the carbonic anhydrase inhibitory effect is more active.[11] Its prolonged use, therefore, could sometimes result in metabolic hypokalemic, hypochloremic alkalosis.[7]

Naturetin—effective diuresis with more favorable electrolyte balance

Other thiazides followed—with improvements being aimed at two particular areas: 1. attempts to increase diuretic action in relation to the milligram potency of the drug, and 2. attempts at a more favorable sodium/potassium ratio in the urine, i.e., to decrease the excretion of potassium while maintaining the excretion of sodium.[12]

One of these, Naturetin, Squibb Bendroflumethiazide, has made advances on both these points. "By adding a 3-benzyl radical to hydroflumethiazide a rather dramatic reduction in dose range is accomplished. With this drug, effective sodium excretion is obtained with doses between 2.5 and 10 mg., which is a 200 to 1 ratio as compared to chlorothiazide..."[13]

Moreover, due probably to its virtual lack of carbonic anhydrase inhibition, Naturetin (bendroflumethiazide) has been shown to cause less potassium and bicarbonate loss and less alteration in urinary pH than either chlorothiazide or hydrochlorothiazide.

Naturetin is outstandingly effective not only in establishing, but also in maintaining, excretion of retained fluid in edematous patients. And its duration of action is sufficiently prolonged to allow a single daily administration in most patients. Naturetin is also an effective antihypertensive agent.

Contraindications: Severe renal impairment; previous hypersensitivity.

Warning: Ulcerative small bowel lesions have occurred with potassium-containing thiazide preparations or with enteric-coated potassium salts supplementally. Stop medication if abdominal pain, distension, nausea, vomiting, or G.I. bleeding occur.

Precautions: The dosage of ganglionic blocking agents, veratrum, or hydralazine when used concomitantly must be reduced by at least 50% to avoid orthostatic hypotension. Electrolyte disturbances are possible in cirrhotic or digitalized patients.

Side Effects: Bendroflumethiazide may cause increases in serum uric acid, unmask diabetes, increase glycemia and glycosuria in diabetic patients and may cause hypochloremic alkalosis, hypokalemia; cramps, pruritus, paresthesias, and rashes may occur.

Supplied: Naturetin (Squibb Bendroflumethiazide) 5 mg. and 2.5 mg. tablets. Also available Naturetin c̄ K [Squibb Bendroflumethiazide (5 or 2.5 mg.) with Potassium Chloride (500 mg.)]. For full information, see Product Brief.

Tumor Conference

Esthesioneuroblastoma

EIGHTY CASES of esthesioneuroblastoma, or olfactory neuroblastoma, have been reported since the original paper by Berger, Luc and Richard.[1,2]

This neoplasm is seen frequently during the second, third, and fourth decades of life. It has been reported in a child eight years old and, in a few instances, as late as the eighth decade. Males are afflicted more often than females (61%).[3]

The most common symptoms are nasal obstruction and epistaxis, which may be present for months or years. In advanced cases rhinorrea, lacrimation, and frontal headache may be present. Physical examination discloses a polipoid mass in the nasal fossa, but the exact site of origin is difficult to ascertain.[4] Radiological examination shows haziness of the ethmoid and frontal sinuses and in the more advanced cases, cloudiness of the maxillary antrum.

The tumor usually arises from the olfactory mucosa of the upper or middle meatus, middle turbinate, or the roof of the nasal fossa at the level of the olfactory plate.

Microscopically, the tumor is composed of either neurocytes or neuroblasts. Pseudo-rosettes or, less often, true rosettes are seen. Fibrillar component is found in a small number of cases. Histologic pattern and prognosis are not related.

Esthesioneuroblastoma should be differentiated from neuroblastomas arising from the adrenal. The latter are usually in the retroperitoneal space or posterior mediastinal structures but at times metastasize to the orbit and related structures. On the other hand, there is a low incidence of distant metastasis with esthesioneuroblastomas; but their local recurrence rate is high.

No single method of treatment is considered satisfactory. In many instances local recurrence calls for retreatment by the same or other means. A combination of surgery, radiation therapy, and occasionally local fulguration and judicious temporization may be required. Conservative management is usually wise in older patients.

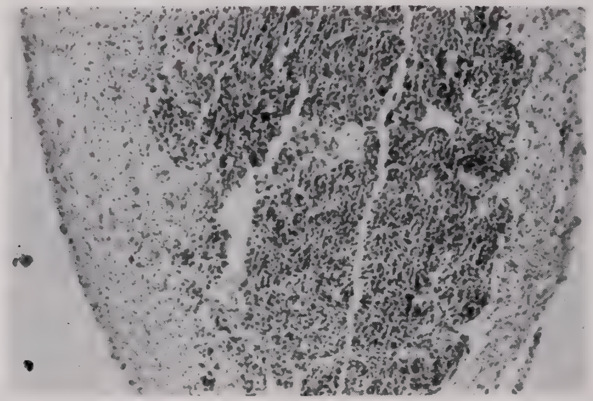
Case History

A 71-year-old white male was seen at the Oncology Hospital of the National Medical Center, Mexico City, Mexico, July 28, 1964. He had had jaundice in 1926 and

Continued

subtotal gastric resection for peptic ulcer in 1931. He gave a history of chronic bilateral otitis media of several years duration. Residual right deafness ensued. In 1945 and in 1961 he had had myocardial infarctions. On admission he said he had experienced left-side nose bleed and a thick, yellow-green discharge for two months. Physical examination disclosed a perforation of the anterior and superior portions of the nasal septum measuring one cm. in diameter and a pink-greyish lobulated mass filling the upper part of the left nasal fossa.

Laboratory tests were normal. Roentgenograms of the paranasal sinuses showed a soft-tissue mass filling the left nasal fossa with partial destruction of the nasal septum and the medial wall of the left maxillary antrum. A biopsy of the mass was reported as esthesioneuroblastoma. Because of the patient's advanced age and his history of heart disease, surgery was not performed. He was given radiation therapy; 5950 rads were administered within an eight-week period. He did well and the mass disappeared.



In April of 1965 his epistaxsis recurred, as shown by a biopsy from the anterior part of the left middle turbinate. Repeat radiation therapy was recommended, and he received 2000 rads from April 22, 1965, to May 8, 1965. At present he is free of symptoms, but a recent biopsy from the same left middle turbinate has shown persistent disease.

Discussion

Neither surgery nor radiation gives a uniformly high cure rate with esthesioneuroblastomas. Either may be used initially or on recurrence. Pathologists may misinterpret the first biopsy and call it an anaplastic epidermoid carcinoma. If the patient survives and has multiple recurrences and an unexpectedly long survival, the disease shows a stubborn tendency to recur locally and may kill by extension to the brain.

Summary

A 71-year-old male, with a two-month history of left-side nasal bleeding and mucopurulent discharge, was found to have an esthesioneuroblastoma. He was treated with two courses of radiation, with a total of 7950 rads being given. He is at present asymptomatic; but a recent biopsy has shown persistent tumor.

Luis G. Krause, M.D.*
Mexico City, Mexico

---

Comment

Dr. Krause's case report brings to mind a moral: rare tumors with confusing names may get lost in dark corners of old medical journals. The problem with the esthesioneuroblastoma is that the esthesioneuroblast, a hypothetical, primordial cell which supposedly arises from the olfactory placode, has never been seen and, indeed, has yet to find its way into medical dictionaries. To compound the semantic difficulties, the esthesioneuroblastoma does not act like a childhood neuroblastoma. It occurs in the older age groups and is an indolent, recurrent growth that kills slowly if it kills at all. Finally, to further muddy the meaning, the esthesioneuroblastoma is purported to arise from olfactory elements (it is sometimes called an olfactory neuroblastoma) ; yet it does not destroy the sense of smell. Because it arises from inside the nose and looks histologically like a neuroblastoma, intranasal neuroblastoma seems a good name.

I suspect that these nuances of nomenclature have piqued the nosological curiosity of more than one physician, and that many esthesioneuroblastomas languish in the files, classified as "atypical, anaplastic carcinomas." Although the original description appeared in France in 1924, an article did not wash into the shoals of the American literature until 1951.[5] As more cases appeared, Mayo clinical physicians caught the scent and, in a retrospective review of their files, came up with eight cases — nearly 10% of those reported to date.[6] Whether one wishes to call the tumor an esthesioneuroblastoma, an olfactory neuroblastoma, or an intranasal neuroblastoma, these facts are clear: the tumor is malignant; it invades locally, recurs after treatment, and is capable of metastases; neither radiation nor surgery is completely effective in checking its growth.

Derivatively Speaking

Sometimes material dissolved in the bile settles out in little crystals which may collect into hard masses. If these get stuck in the bile duct and form an obstruction, the result is pain and possible surgery. Such masses are called *gallstones* (never "bilestones" since *stone* is from the Anglo-Saxon). On the other hand, the Latin word for a small stone is "calculus" (plural, "calculi") and this name may be used for gallstones. But, because of the change to Latin, they are never called "gall calculi," but always *biliary calculi.*

When gallstones obstruct the way to the intestines, the bile being formed by the liver backs up and is forced into the blood stream. The material in bile consists in part of strongly colored compounds called *bile pigments* (never "gall pigments" because *pigment* is from the Latin "pingere," meaning "to paint").

From Isaac Asimov's Words of Science and the History Behind Them.

Most of my patients with high blood pressure are as old as I am. A lot of them are living on pensions. They're grateful when I can keep prescription costs down.

Regroton®

chlorthalidone 50 mg, reserpine 0.25 mg.

1 tablet daily brings pressure down

Advantage: Both components of Regroton are long-acting.
Average dosage: One tablet daily with breakfast.
Contraindications: History of mental depression, hypersensitivity, and most cases of severe renal or hepatic diseases.
Warning: Discontinue 2 weeks before general anesthesia, 1 week before electroshock therapy, and if depression or peptic ulcer occurs. With administration of enteric-coated potassium supplements, the possibility of small bowel lesions should be kept in mind.
Precautions: Reduce dosage of concomitant antihypertensive agents by one-half. Discontinue if the BUN rises or liver dysfunction is aggravated. Electrolyte imbalance and potassium depletion may occur; take particular care in cirrhosis or severe ischemic heart disease, and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended. Use with caution in patients with ulcerative colitis, gallstones, or bronchial asthma.
Side effects: Nausea, vomiting, diarrhea, muscle cramps, headaches and dizziness. Potential side effects include angina pectoris, anxiety, depression, drowsiness, hyperglycemia, hyperuricemia, lassitude, leukopenia, nasal stuffiness, nightmare, purpura, urticaria, and weakness.
For full details, see the complete prescribing information.
Availability: Bottles of 100 and 1000 tablets.

Geigy

Neuro-Pediatrics Conference

Battered Child Syndrome*

Dr. A. J. Ellinger:**

This five-month-old white female was brought into my office on February 23, 1965. The mother said that three days before, while the father was babysitting, he propped a bottle of water for the child and went into another room. The father is partially deaf, but he apparently heard the child coughing and choking, went to her, and found that she was not breathing. Mouth-to-mouth resuscitation was given for forty-five minutes. When questioned as to why a physician was not called, the mother stated that no phone was available and that the child responded and apparently seemed well throughout the night. One day prior to being seen, the child began vomiting and continued to do so until she was seen in the office. It was also stated by the mother that the child began to have some twitching of the left arm and left leg, especially after crying a great deal. She was also very irritable. Further questioning of the mother revealed that three or four days prior to the episode of asphyxia, the child had fallen out of a chair about two feet high and struck her head. However, there was no loss of consciousness and she appeared normal.

Past history revealed that the child had a spiral fracture of the right femur on December 16, 1964, which was reported to have occurred when the father was carrying her and her leg struck a door jamb. Dr. McCarthy of the Willmar Clinic cared for her at that time.

The child was born at Fairmont, Minnesota, following a normal pregnancy and delivery. She weighed six pounds, nine and one-half ounces at birth, and no difficulties were noted in the neonatal period. At six weeks of age the child still weighed six pounds, nine and one-half ounces; at four months of age, ten pounds, two ounces. She had received two diptheria-pertussis-tetanus shots and oral polio while living in Fairmont but had had no further medical evaluation since moving to Willmar.

---

*Sponsored by the U. S. Public Health Service Grant N2502A63. These conferences are an integral part of the Comprehensive Clinic Program at the University of Minnesota Hospitals. The pediatrics conferences are held every Wednesday from 1:00 to 3:00 p.m. The adult conferences are held every Thursday at 4 p.m. Co-ordinators for the project are Dr. Charles Branthaver and Dr. Edward Defoe in Pediatrics, and Dr. Robert Soll, in Adult Neurology.

Held Wednesday, April 21, 1965 at the University of Minnesota Medical School.

See It's the Law, Page 1359, and Minnesota Med 46:922, 1963.

**Referring Physician, Willmar Clinic, Willmar, Minnesota.

Continued

Physical examination revealed a temperature of 100.6 degrees rectally, head circumference, 39.5 cm., height, 24 inches, and weight, 10 pounds, 6¼ ounces. The child was pallid; no respiratory difficulty was noted. The fontanel was small; there was no tension or bulging noted. The pupils were equal bilaterally and the eye grounds not well visualized. The remaining physical examination was normal with the exception of the neurological tests which showed equivocal extensor toe signs, unsustained bilateral clonus, and brisk reflexes. No spasticity and no convulsive episodes were noted at this time.

The child was admitted to Rice Memorial Hospital for evaluation. She was initially dehydrated, but the electrolytes were normal except for the CO_2 which was 10.2 mEq/L. Urinalysis and white count were normal. The hemoglobin was 10.5 gm.%. X rays of the skull were obtained and showed the sutures to be definitely widened. A bone survey was found to be negative for other fractures except for the healed fracture of the mid-shaft of the right femur.

Subdural taps were performed and definitely bloody fluid was encountered in the right subdural space; the left side was entirely negative. Following the taps there was a moderate amount of leakage of a serosanguinous nature from the right.

A cut-down on the vein was performed and the patient was given one-third normal saline. While she was in the hospital, definite Jacksonian type convulsive movements were noted in the left extremities, and there was a slight paresis of the left side with some spasticity. The child was referred to the University Hospitals for further evaluation.

Dr. Burton Dudding:* Upon arrival at University Hospital, the child was alert and responsive. On review of system history it was learned that the child did bruise easily with spanking, and these bruises lasted two to three days over the buttock region. There was no family history of any bleeding disorder. Social history will be given later in the discussion.

Physical examination at the time of admission showed a small, poorly nourished white female with an active intravenous infusion attached. The skull was asymmetrical with a bulge on the right side. Funduscopic examination showed diffuse bilateral preretinal hemorrhages and vitreous hemorrhage on the right. Fullness of the right thigh was noted, as well as weakness of the left arm and leg. The weight was 5.2 kg., which is below the 10th percentile; the length was in the 50th percentile. Neurological examination showed a slight ptosis of the left eyelid and a slightly drooping angle of the mouth on the left. The patient would not reach for objects with the left hand, which was slightly flaccid and lying at the side. Muscle tone was definitely decreased in the left arm and left hand. On the right the patient had a good grasp reflex, not obtainable on the left. There was no evidence of spasticity or scissoring; the extensor tone in the lower extremities was good.

Laboratory studies showed a normal white count and urinalysis. The hemoglobin was 9.6 gm.%. A bleeding workup revealed a normal partial thromboplastin time, prothrombin time and platelets. Roentgenograms showed not only the healing fracture of the right femoral shaft, but periosteal new bone formation of the shaft of the left femur. No other evidence of trauma was present.

---

*Pediatric Intern, University of Minnesota Hospitals.

A repeat subdural tap was performed and approximately 1 cubic centimeter of bloody fluid was obtained from the right side; none was obtained from the left. The patient tolerated these procedures well. Eight days after admission another repeat right subdural tap was performed and no fluid obtained.

An electroencephalogram was compatible with a subdural on the right side. During the first two weeks of hospitalization the patient continued to vomit intermittently; consequently the caloric intake was less than expected. By the end of the second week she was taking 120 calories per kilogram and beginning to recover muscle function of the left side. On discharge, March 21, 1965, she had gained weight satisfactorily, and during the previous two weeks had shown signs of rapid clinical improvement from the neurological standpoint.

Initial impression was that this child presented an instance of the Battered Child syndrome by virtue of the following reasons:

1. The patient had a history of apnea which required resuscitation with mouth-to-mouth breathing by the father for forty-five minutes; but no medical attention was sought by the parents after this episode.
2. There was insufficient historical data to account for either the subdural hematoma or the bilateral preretinal hemorrhages.
3. There was a past history of fracture of the right femur, again with little historical data to account for this fracture as entirely accidental; also the skeletal survey showed evidence of residual periosteal hemorrhage of the left femur.

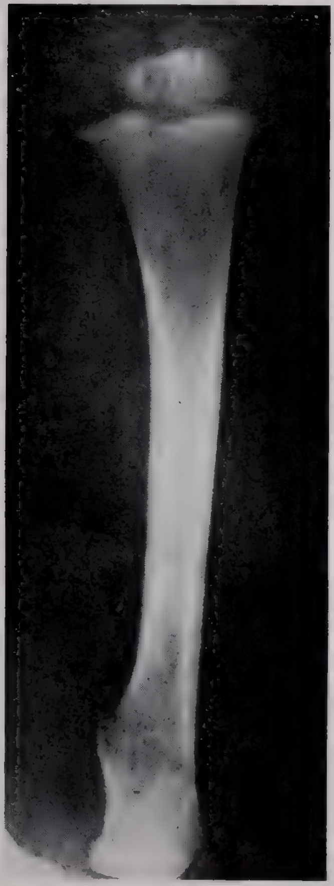

Fig. 1 — Roentogenogram of left femur showing periosteal new bone formation which is associated with trauma.

Continued

4. The mother admitted that the child bruised easily when she spanked her for crying.

5. The patient's weight gain was poor in contrast to normal growth in length, and no metabolic or other basis could be found to explain the findings.

6. The family and social history were compatible with the diagnosis of Battered Child syndrome, since surveys have revealed that over 50-90% of children who show the effects of this syndrome are the products of unwanted pregnancies and of serious social problems.[1,2]

Miss Helen Kretchmer:* Once the diagnosis of Battered Child syndrome was established, the philosophy was to help these parents as much as possible and not to instigate punitive procedures. The protocol used by the University Hospital was a telephone call to Mrs. Nelson, the social caseworker in Willmar, as well as a report from the hospital administration to the police in Willmar. These calls were followed by a letter regarding the total situation.

The father, aged 21, is currently in his first year of a two-year college course studying to be a draftsman under the Vocational Rehabilitation program. This support consists of tuition, books, and $20 a week for living expenses. He has a 75% bilateral congenital hearing loss and wears a hearing aid. He plans to take a job in June, 1965, in St. Cloud, Minnesota. The mother, aged 18, left high school in her junior year because of this pregnancy. Because of serious financial problems she is currently working as a waitress in a local cafe from four p.m. to midnight four days a week. The parents were married March 26, 1964, and the patient was born October 1, 1964. Both grandparents apparently did not favor the marriage but did support it. According to the mother, the father's side of the family represents an unstable situation; his nine-year-old sister has had a nervous breakdown apparently precipitated by the father's activities with other women. The mother's family is relatively stable. The young mother expressed her wish to finish high school and at one time wanted to become a neurosurgeon. She read a great deal and acquired no familiarity or experience with child-rearing practices.

When the parents established their home in Willmar after the birth of the baby, they had many adjustments to make. The baby slept in the same room with the parents, and she seemed to cry excessively. The mother became very irritated at the baby's crying, especially in the morning after she had worked the previous evening. She admits that this crying often caused her to lose her temper and spank the baby. The father, on the other hand, does not seem to be too disturbed by the child since he can shut off his hearing aid. The ideas expressed by both parents on child rearing are both inconsistent and immature.

When this child was discharged from the hospital she was placed in the care of the maternal grandparents; but no action has been taken for legal custody either by the maternal grandparents or by Martin County.

Dr. Harold Ireton**

A screening evaluation of the child's intellectual functioning by the Cattell Infant Intelligence Scale was made. On the basis of this test the child seemed to be functioning with approximate consistency for her age.

---

*Medical Social Worker, University of Minnesota Hospitals.

**Clinical Psychologist, University of Minnesota Hospitals.

In view of the history one would be somewhat hesitant to make any prognosis at this time; certainly she should be re-evaluated, preferably at age two, unless there is evidence of obvious developmental defects prior to this time.

The Parents

Both parents presented as friendly and cooperative, although the mother appeared somewhat superficial in her emotional expression, and the father appeared somewhat tense. Although they both admitted that they had been somewhat harsh in the way they handled their child, they supported each other's contentions that they had not been extreme in their handling. The mother reported that the child deserved the spankings that she got and the father added, "You have to do something to shut her up." In describing the episode preceding the child's hospitalization, the father stated that he slapped her "because she wouldn't stop crying. I was under pressure . . . a final test coming up . . . she fought me, cried . . . I slapped her." The mother reported that her spankings may have "bruised her a little bit." Regarding their marriage, both deny major problems; however, they admit that they had to get married. The impression is gained that there are significant husband-wife conflicts which both parents minimize or deny.

The Mother

The mother's history also includes a suicide attempt at age 13 with aspirin "because my brother picked on me." From the interview material the mother attempts to present herself as intelligent, mature, and interested in the welfare of her child. Basically, however, she appears quite immature, manipulative, and unwilling to accept adult responsibility. She appears rather self-centered and probably is quite emotionally detached from the needs of others.

The Father

The father is somewhat tense and on the defensive, although he did communicate considerable information. Personality testing tended primarily to reflect this defensiveness, although it did point to features of anxiety and emotional instability. In the interview he stated that everyone in his family had always been nervous and touchy. He is apparently doing well in school but acknowledges considerable tension in connection with multiple responsibilities of finance, family and school. By history, he has suffered numerous handicaps to normal development. Physical problems have included tunnel vision, hearing deficit, and an associated speech problem. He reports that he could not say his own name until junior high school when he was provided with a hearing aid. He could not live up to his father's ambition that he be a boxer like himself and fell primarily under the social influence of his mother and sisters. This pattern of physical and social disabilities has apparently left him quite insecure in his masculine identity, although he does not directly acknowledge this; however, a paranoid sensitivity is subtly indicated. Consistent with this, following an auto accident four years ago, he was apparently confused and suspected that everything was poisoned.

Both parents appear limited in their ability to provide for their daughter emotionally, but for different reasons. The mother appears to be psychopathic in her emotional detachment from the needs of others, while the

Continued

father is quite insecure, sensitive, and wrapped up in the struggle to maintain his defenses against his own insecurity and anxiety. This situation would suggest an unfortunate future for this marriage unless changes can be made.

As far as recommendations are concerned, it is essential that the parents receive psychological counseling. This should be provided locally in Willmar through the mental health center.

Dr. Kenneth Swaiman:* The condition we are discussing today is certainly not new, but it is only recently that physicians have recognized the connection between subdural hematomas and multiple long-bone fractures.[3,4] Caffey[3] originally thought this complex was due to a metabolic disease. The primary implications of the Battered Child syndrome are that a great majority of these children die from brain trauma or have serious sequelae; the bones heal but the brain does not. This patient demonstrated some of the immediate signs one notes in the diagnosis of a subdural hematoma: seizures which are not necessarily focal in nature and loss of contact with the environment. The small volume of the subdural hematoma does not explain the entire clinical picture. One must assume that there was brain contusion which probably consisted of intracerebral hemorrhage and edema. The electroencephalogram revealed slowed fast activity and slow-wave foci compatible with subdural hematoma as well as with underlying brain damage. However, the usual prognosis of a subdural hematoma may not be applicable to this child. Usually, in infants, cranial sutures are not rigid and tend to spread; thus there is room for expansion of the underlying pressure. From history, one can not be sure whether this child has had more episodes of cerebral damage.

This child did show improvement in the left hemiparesis, which indicates some resolution of the right-sided injury of the brain. In the future, speech problems are less likely to occur, because 99% of the people who are right-handed have the speech center on the left; and of those who are left-handed, 90% have the speech center on the left. We have no guarantee that this child may or may not have seizures in the future. She should be maintained on small doses of phenobarbital for the next year.

I would agree with Dr. Ireton in being skeptical of her future development, judging solely on the basis of her motor ability at this time. In regard to management of her subdural hematomas I doubt whether there would be any need for surgery, and we will follow this child by periodic skull transillumination and head measurements. Electroencephalography may not be as helpful, as the changes seen may be permanent.

Dr. Dudding: When this child was discharged from the hospital, she was released to the care of the maternal grandparents, and legal custody has not been insured. When she was last seen, she was gaining weight and seemed to be making an excellent recovery.

Mrs. Lucille Nelson:** This family's initial contact with the Willmar Welfare Department was as a transient couple in financial need for medical care. They seemed to be very immature in their ability to care for their baby, and she was very difficult for them to accept. Following the hospitalization of their child the parents returned to their home. Unfortunately, the police, when they were notified of a possible battered child, did not in turn notify the welfare department as to their course of action, but took it upon themselves to interrogate the parents and were apparently a "little rough." The sheriff later apologized for this. I was somewhat hesitant in approaching the family as I felt that there might be resistance as a result of the police interrogation. However, at the time of the interview the father seemed quite relieved, and both parents appeared to be seeking support. Both expressed the wish that their child would soon be returned to them; however, their routine seemed to be "better now since the child was not in the home."

**Child Welfare Social Worker, Kandiyohi County.

During a second visit with the parents they were encouraged to attend the West Central Mental Health Center for evaluation. This was done, and a staffing conference was held. In general, conclusions were that the child should be maintained in the maternal grandparents' home until this couple has been settled in their new home and show definite evidence that they have some realization of their responsibilities, while making consistent efforts to improve.

Mrs. Mary Jean Campbell:* I would certainly recommend that cooperation and good communication between the various communities involved be stressed. This can be done on an inter-county basis by maintaining continuity of communication, when this family moves to St. Cloud. As this child is presently with the grandparents in Iowa, I strongly feel that the University Hospitals should maintain the primary medical responsibility until this family is settled in St. Cloud. Also legal custody by Martin County should be obtained to prevent the child from being returned to the present home situation.

Dr. Robert ten Bensel:** Mrs. Campbell's points are well taken. It is extremely important that legal custody be taken of the child to insure that she does not re-enter the home until the family is under casework services. DeFrancis[5] points out that physical abuse will continue if children are returned to a home where the personality disorders of the parents go untreated. Repeated physical abuse has reoccurred in as many as 40% of such cases. The incidence of death in these cases in unknown.

The situation described by Mrs. Nelson merits some comment. A revision of the Minnesota Battered Child Law is presently before the state legislature and will insure the dual reporting and cooperation of the police and county welfare departments in these cases.†

Final Recommendations of the Conference:

1. Since the child is presently with the maternal grandparents in Iowa, the University Hospitals will maintain medical responsibility until this family has made the move to St. Cloud and a final disposition is made through the mental health center and county welfare department.

2. Medically, this child needs to be maintained on phenobarbital for the next year as a prevention against seizures. Secondly, she should be reevaluated psychologically at two years of age for possible residual damage. Careful observation should be maintained to determine whether the subdural reaccumulates.

3. We cannot over-emphasize restorative measures for the family. Every

Continued

possible attempt should be made within the community to insure that the parents realize their responsibilities and make efforts to assume them. However, from the above discussion this will be a difficult task in view of the psychopathology of the parents.

4. Legal custody of the child by Martin County is recommended until the family situation is resolved and a legal decision is made regarding the advisability of returning this child to her home or placing her permanently elsewhere.

5. Inter-county communications should be maintained as to progress with the family. Communications to the University Hospitals should be made to Dr. Dudding or Dr. Swaiman.

The Stethoscope Discovered

Laennec* had under his care an exceedingly stout woman suffering from heart disease. Listen as he might, he could not hear the heart sounds clearly. On his way to visit this patient, Laennec was passing through the courtyard of the Louvre. A heap of old timber was lying in one corner, and some children were playing there. They had discovered a new game. One of the pieces of wood was a long beam. A youngster had his ear at one end of it, and another was signalling by tapping the other end. This gave Laennec an idea. He quickened his steps, and, when he reached his patient asked for a quire of letter-paper. Having rolled this paper into a cylinder, he applied one end of it to the site of the cardiac impulse and listened at the other end. The result was marvelous. He could hear the heart-sounds much better, much more plainly, than with his ear on the chest. Moving his paper cylinder from place to place, he listened to the sounds that were forthcoming all over the heart. Then he listened to the breath-sounds. They were so loud that they startled him. The stethoscope had been discovered, the auditory tube which was to become symbolical of latter-day physicians as the urine-glass was of the medieval doctor.**

Medical Seminar

Diagnosis and Treatment of Regional Enteritis

Presented as a Seminar

Sponsored by

The Faculty of the Mayo Graduate School of Medicine

REGIONAL ENTERITIS is a granulomatous disease of the gastrointestinal tract, which has been reported to occur anywhere from the esophagus to the anus but which most frequently affects the last 12 inches of the ileum.[1,2] It is characterized pathologically by noncaseating granulomata and by thickening of all layers of the intestinal wall and its mesentery. Clinically it is associated with a long course, punctuated by remissions and exacerbations. Our ignorance about its etiology remains almost as complete now as it was in 1769, when the disease was first described.[3]

Primarily a disease of young people, regional enteritis can occur at any age. In 40% of cases it affects persons aged 21 to 30 years and, in 85%, those aged 10 to 40 years. The sexes are almost equally afflicted, but male patients are slightly more commonly represented in most series. There seems to be little racial predilection,[1,3] although some authors have found a higher incidence in members of the Jewish race.[4]

Classification

We can classify this disease into four major categories, recognizing that overlapping of one category into another does occur: (1) acute regional ileitis, (2) ileojejunitis, (3) regional enteritis affecting the colon, and (4) chronic regional enteritis (most common type). Regional enteritis involving the esophagus, stomach, or duodenum is quite rare and will not be discussed.

Acute Regional Ileitis

Acute regional ileitis[1] presents with a clinical picture nearly indistinguishable from that of acute appendicitis. The patient has the acute onset of crampy abdominal pain, tenderness in the right lower quadrant of the abdomen, and mild fever. Frequently a lower-abdominal mass may be felt. At operation, the findings of a congested, boggy ileum, heavily matted onto nearby intestine, and of enlarged mesenteric lymph nodes allow the surgeon to make the diagnosis of acute regional ileitis. This is essentially an operative diagnosis, for clinical differentiation from appendicitis is quite difficult. The only possible differentiating point is that in acute regional ileitis there is the onset of diarrhea at the same time as the pain begins. This is unusual in appendicitis, where the patient is usually constipated. Since exceptions to this rule do occur, operation is almost mandatory.

If there is no history of chronic diarrhea antedating the acute episode, the prognosis is quite good; there is then a 50% to 90% chance that the patient will recover completely.[5,6] Chronic diarrhea, existing prior to the acute episode, is thought to indicate a preexisting chronic regional enteritis.

Ileojejunitis

Ileojejunitis may be defined[1] as that form of chronic enteritis in which the granulom-

Continued

atous process typical of that disease involves the jejunum, either as an extension from the ileum, or as an independent lesion limited to parts of the upper portion of the small bowel. Ileojejunitis resembles regional enteritis closely in clinical manifestations, except that malabsorption and malnutrition are more common in the former. In general, its clinical course is more benign than that of classic regional enteritis; however, because it often involves large segments of bowel, it is also less amenable to surgical correction.

Regional Enteritis Affecting the Colon

It is now thought by leading authorities[7] that this clinical and pathologic entity is separate from chronic ulcerative colitis. The differential points relate mainly to differences in distribution and appearance of the local lesions. The rectum is involved in 95% of cases of ulcerative colitis but in only 50% of cases of colonic regional enteritis. On the other hand, anal lesions are much more common in regional enteritis affecting the colon, occurring in about 80% of persons having this disease. The most characteristic lesion here is a perianal ulcer; this is indolent-appearing, undermined, and quite chronic. In some clinicians' hands, biopsy of this lesion will show noncaseating granulomata in 85% of cases.[7]

Further, in the roentgenologic examination of patients having regional enteritis of the colon, one will see only sporadic involvement, with islands of normal-appearing mucosa interspersed among areas of deep ulceration, which give diseased segments of colon a "feathered" appearance. In ulcerative colitis the colon is usually more diffusely involved, and the ulcers which one sees are quite shallow. Further, internal fistulae between the colon and other organs are rare in ulcerative colitis but relatively common in regional enteritis of the colon.

In this disease, proctoscopic examination may show typical deep linear ulcerations; the mucosa may be swollen, giving it a cobblestone appearance. In contrast, in ulcerative colitis, proctoscopy reveals broad, flat, superficial ulcers; and the mucosa is granular and friable, bleeding easily. Thus the patient having ulcerative colitis usually has gross blood in his stools; whereas the patient with regional enteritis of the colon rarely has.

Finally, persons having regional enteritis of the colon are very seldom seriously systemically ill ("toxic") from their disease. In fact, to date, no case has been reported of acute toxic megacolon in regional enteritis.[8] This is, of course, very different from what occurs in chronic ulcerative colitis. However, it should be stressed that in some few cases there is no way of telling whether a patient has chronic ulcerative colitis or regional enteritis, even when the operative specimen is in the pathologist's hands.

Chronic Regional Enteritis

This is the common form of the disease and will be the subject of the remainder of this paper. Here the terminal 12 inches of the ileum are involved primarily.

Burril Crohn, whose paper in 1932 brought regional enteritis to the attention of the medical profession, maintained[1] that "the diagnosis is essentially a clinical one, based upon the characteristic subjective symptoms and the physical findings." While we have all seen or heard of cases of regional enteritis in which no one could have made the diagnosis clinically, certainly we can be suspicious of regional enteritis in appropriate cases, if we learn the characteristic clinical picture.

Clinical Findings

Common Symptoms and Signs

The most common symptoms and signs of regional enteritis are shown in Table 1. (Percentages are based on 1,342 cases reported in four series.)[1,3,9,10]

Abdominal Pain. — The pain is usually colicky and localized in the lower part of

TABLE I
Symptoms and Signs of Regional Enteritis

Symptoms	Cases, %	Signs	Cases, %
Abdominal pain	93	Fistulae	52
Diarrhea	84	Mass	32
Loss of weight	41	Anemia	20
Fever	36		

the abdomen, frequently in the right lower quadrant. It is often preceded by eating and is relieved by defecation or the passage of flatus. This is the characteristic predefecation pain of regional enteritis. It is probably caused by partial obstruction of the small bowel.

However, there is another kind of pain which a patient with regional enteritis may experience. This is a steady dull pain, usually in the right lower quadrant, not relieved by defecation. Often a sign of abscess or fistula formation, this pain occurs late in the course of the disease.

Diarrhea. — This symptom also has certain distinctive clinical features. Following the general rule that diarrhea decreases in intensity the farther away the lesion is from the anal sphincter, in the usual case of regional ileitis diarrhea is moderate. The patient may have two to five stools per day. The stools are soft and mushy and may contain just a bit of mucus but no pus. Gross blood in the stool is rare; indeed, the guaiac test for blood in the stool may give negative results in cases of regional enteritis. Occasionally, in about 5% of cases, the patient is constipated.[1]

Loss of Weight. — Loss of weight averages 10 to 20 pounds but may be much greater. In far-advanced cases the patient may look as cachectic as someone with terminal carcinoma. The mechanisms in operation here include the patient's aversion to food (since eating aggravates the pain), malabsorption, intestinal hurry, and internal fistulae.

Fever. — Fever occurs mostly during the inflammatory stages of the disease; it is usually absent in remission or in the late, cicatrizing stages. The fever is usually low-grade and not accompanied by chills. However, if the fever is high and runs a septic course, then one must suspect the occurrence of an intra-abdominal fistula, abscess, or perforation. If the pain and diarrhea are mild but fever is prominent, regional enteritis may present as "fever of unknown origin."

Abdominal Mass. — In this disease, such a mass is usually found in the right lower quadrant of the abdomen and consists of an abscess or of inflamed adherent loops of bowel, often interconnected by fistulous tracts. The size of the mass varies; it may have the diameter of a 50-cent piece or may be larger than an orange. On occasion, it may be felt only on vaginal or rectal examination.

Anemia. — The anemia that is present in about 20% of cases consists, for our purposes, of a hemoglobin value of less than 11 gm/100 ml. of blood. The mechanisms involved in the production of this anemia include chronic blood loss, malabsorption of iron and other substances, and the occasional blind-loop syndrome.

Fistulae. — Three types of fistulae occur in regional enteritis: internal (41%), external (22%), and perirectal (38%).

Internal Fistulae (41%) — In almost all cases, these originate in the diseased terminal ileum and communicate most commonly with the cecum and more proximal portions of the ileum, but fistulae have extended to the sigmoid colon, urinary bladder, vagina, fallopian tubes, urethra, and so on. These are usually seen easily on roentgenograms and are quite characteristic of regional enteritis. The precursors of these fistulae are probably the deep linear ulcers seen in diseased portions of intestine.

External Fistulae (22%) — These ordinarily open onto the anterior abdominal wall and practically never occur without an antecedent abdominal operation, usually an appendectomy. The sequence of events is much like this: the patient has an operation, and the incision heals well at first; however, within five weeks the incision breaks down and a small fistula appears, which may persist for months or years. The fistula may not be apparent until years have gone by, but in more than 75% of cases, it will be seen within five weeks.[1] It usually exits at the incisional site, but the external opening may on occasion be seen anywhere in the abdomen-inguinal region, psoas region, and so on. It has been postulated that when the surgeon breaks down adhesions with his exploring hand, he may enter

Continued

an abscess cavity, which then breaks out through the traumatized abdominal wall.

Perirectal Fistulae (38%) — These occur in more than 20% of cases of regional enteritis, if we include rectovaginal fistulae.[11] Interestingly enough, they may antedate the abdominal symptoms of the disease by years. In one series,[11] rectal complaints predated the diagnosis of regional enteritis by at least one year in 29% of all cases of regional enteritis seen at the institution where the study was made.

Uncommon Signs and Symptoms

Less common manifestations of regional enteritis include arthritis (3% to 8%), clubbing (3% to 4%), ocular difficulties (5%), erythema nodosum (1% to 2%), and splenomegaly (1%). The arthritis may be rheumatoid-like or like ankylosing spondylitis. The severity of the arthritis parallels closely the activity of the intestinal disease, often disappearing during a remission. In no case is there a positive rheumatoid flocculation.[10] The clubbing is indistinguishable from that which occurs in pulmonary disease and is important only for that reason. We must remember that regional enteritis causes clubbing and not subject a patient with regional enteritis and clubbing to a lot of unnecessary pulmonary tests. The eye problems seen are quite varied; iritis and iridocyclitis are the most common, but keratitis, corneal ulcers, episcleritis, and phlyctenular conjunctivitis have all been described.

Proctoscopic Findings — There are, all in all, six proctoscopic clues to the diagnosis of this illness.[11] Proctoscopic examination may reveal one or more of the following: (1) anorectal abscesses and fistulae, (2) indolent anal or perianal ulceration, (3) extrarectal or intra-abdominal masses, (4) deep, linear ulcers of the mucosa, (5) cobblestone appearance of the mucosa, and (6) granulomas of the rectum or sigmoid colon.

We have already mentioned most of these clues in discussing regional enteritis of the colon. Suffice it to say that the frequency of all these signs is greatest when colon and rectum are involved, as might be expected. In summation, suppurative perianal fistulae in the presence of diarrhea indicate a pathologic inflammatory process somewhere in the intestine. Most commonly this will prove to be regional enteritis, ulcerative colitis, or tuberculosis of the small intestine.

Roentgenologic Findings — When one clinically suspects regional enteritis, one usually seeks confirmation of his clinical impression through gastrointestinal roentgenograms. Since the terminal ileum is involved in more than 90% of cases,[12] often a colon examination will suffice for the initial examination. A practical point here is that we can do a roentgenographic study of the colon even in the presence of subacute obstruction, when small-bowel roentgenography would be contraindicated. Further, this provides us with yet another way of ruling out ulcerative colitis.

The radiologic appearance has been divided, rather arbitrarily, into stenotic and nonstenotic phases, depending on whether or not irreversible fibrosis has occurred.[13] The earliest sign in the nonstenotic phase is caused by submucosal edema and consists in flattening, blunting, and thickening of the valvulae conniventes. The bowel lumen may become irregular. Then longitudinal streaks of barium are seen, representing shallow ulcers; this causes the characteristic cobblestone appearance, best seen in the proximal portions of the intestine. Soon the ulcers become deeper, giving the intestine a feathered appearance. Occasionally, small inflammatory polyps may be seen. Fistulae to other organs may also be seen.

In the stenotic phase, all of the above may be seen; but added to these is the dilatation of the bowel just proximal to the lesion. Fluoroscopically, the stenotic bowel is never seen to fill out with barium.

The famous string sign of Kantor is usually seen in the terminal ileum. It is a thin shadow, said to look much like a frayed cotton string. This sign does not always mean that irreversible stenosis has occurred, for it also may be caused by edema and spasm in the nonstenotic phase of the disease. This string sign is quite suggestive of regional enteritis; indeed, it is present in about one third of cases.[12] However, it is important to remember that other diseases may also present with this sign—for example, actinomycosis and tuberculosis of the small bowel and carcinoid involving the terminal ileum.[1]

Differential Diagnosis

In a recent review, Eisenstadt[14] listed more than 70 different diseases in considering the differential diagnosis of regional enteritis. As space is lacking to discuss all of these, I shall elaborate on only a few interesting diseases with which this disease may be confused (Table 2).

TABLE 2
Some Diseases Which May Be Confused With Regional Enteritis

Ulcerative colitis
Tuberculosis of the small bowel
Mesenteric arterial insufficiency
Carcinoid of the terminal ileum
Irritable bowel syndrome

Ulcerative Colitis

I have already discussed most of the differential points between ulcerative colitis and regional enteritis; the most characteristic differences are seen in the roentgenographic and proctoscopic examinations.

Tuberculosis

Tuberculosis of the small bowel can mimic regional enteritis quite well, a fact of special importance in areas where tuberculosis is endemic. The key feature to remember about tuberculosis of the small bowel is that it almost always co-exists with pulmonary tuberculosis — in this country, at least.[7] Thus a roentgenogram of the chest and a tuberculin test are of special significance. However, the final distinction between tuberculosis of the small bowel and regional enteritis may not be made until the operative specimen is in the pathologist's hands. Caseation or evidence of acid-fast bacilli on tissue examination or culture will then provide proof that the lesion is of tuberculous origin.[14]

Mesenteric Arterial Insufficiency

Chronic mesenteric arterial insufficiency is receiving increasing attention as a clinical entity diagnosable before death. It is not hard to visualize how partial ischemia of a segment of intestine could lead first to inflammation and then to healing, with fibrosis and scarring. This could then, if it involved the terminal ileum, give a small-bowel roentgenographic picture resembling that of regional enteritis. However, mesenteric arterial insufficiency usually occurs in older persons who have evidence of arteriosclerosis elsewhere. These persons have "intestinal angina," in which pain of a crampy nature occurs within 30 minutes after eating. It may be generalized or periumbilical and is often quite severe. However, it is not usually relieved by the passage of stool or flatus, as is the pain of regional enteritis; indeed, it may be resistant to standard medications for pain. The only consistent pain relief occurs when the individual avoids food. Pain is the most predominant symptom here, far more so than the diarrhea which may occur. Diagnosis is important, because surgical treatment is available and may be most helpful. Properly performed angiography of the mesenteric vessels remains the only method of definitive diagnosis short of surgery.[15]

Carcinoid Tumors

Carcinoid tumors of the ileum are rare but deserve mention. Because of their chronicity they may be present for many years, mimicking regional enteritis very well, especially if the full-blown carcinoid syndrome is not present. However, if the patient has severe, persistent flushing or pulmonary or tricuspid murmurs, then it would seem prudent to obtain a urine collection for 5-hydroxyindolacetic acid. If the terminal ileum is not involved in a case suspected of being regional enteritis, then one should be suspicious of carcinoid. However, it is rare for this diagnosis to be made preoperatively.[16]

Irritable Bowel

Finally, one should not forget the ever-present irritable bowel syndrome. This can cause diarrhea, abdominal pain, and, on occasion, mild loss of weight. However, one

Continued

never sees an abdominal mass, fever, or internal fistulae as a part of this syndrome.

In the classic case of regional enteritis, clinical and laboratory studies will confirm the diagnosis with something approaching 99% certainty; the only way to achieve 100% certainty is to confirm the diagnosis at operation.

Treatment

Since this is, in general, a disease characterized by spontaneous remissions which may last for years, it has been exceedingly difficult to evaluate conservative therapy in any objective manner. There have been few double-blind, controlled studies carried out to point scientifically to the most advantageous forms of therapy. Treatment of this disease, therefore, remains to a large extent empirical. Most of the measures which have been advocated include: diet and dietary supplements; rest; the administration of anticholinergics, sulfonamides, antibiotics, adrenal steroids, and nitrogen mustard; irradiation; and operation.

Diet and Dietary Supplements

Different clinicians vary in the severity of the diet they impose on their patients; but in general all agree that the diet should be high in calories, carbohydrate, and protein and at least mildly restricted in residue. It has been suggested that eating five small meals a day might be a good plan, especially for patients who find that eating increases their pain. In the past there has been considerable comment about milk allergy in this disease.[3] However, this is now thought not to be of major importance, and milk is not specifically forbidden unless the patient notes that it causes an increase in his symptoms.

Protein supplementation with a drink containing Gevral protein or a similar preparation may be indicated. Vitamin supplements also are used — B complex, and vitamins A and D. Anemia may call for the use of parenteral or oral iron or for injections of vitamin B_{12}, depending on its cause. If calcium or potassium are lost in sufficient quantity, they also may need replacement. Each case must be considered individually and treated accordingly.

Rest

As in any chronic illness, rest may be very important. However, the patient need not be at bed rest, unless he is febrile. Mental rest is also often prescribed for the patient in the form of various tranquilizers.

Administration of Drugs

Anticholinergic Agents — These are given in order to relieve cramps and delay emptying of the small bowel. Fairly high doses of the various drugs may be necessary. If, on the other hand, diarrhea becomes a major problem, a combination of diphenoxylate hydrochloride and atropine sulfate (Lomotil) is probably the preparation of choice.

Antibiotic Agents — Antibiotics were often tried, on the supposition that this disease looked and behaved much like a low-grade infection. Thus, in the early days of the availability of antibiotic agents, streptomycin and isoniazid were given to patients.[10] Now most clinicians would not use those drugs or the broadspectrum antibiotics unless a complication of the disease, such as the "blind-loop syndrome," were encountered.

However, when beneficial results were seen in ulcerative colitis from the use of salicylazosulfapyridine (Azulfidine), it became only a matter of time until it would be used in regional enteritis. Again, no controlled studies with this drug have been reported, but most clinicians now would be willing to at least try it. In general, however, results have not been nearly as encouraging as they were in ulcerative colitis. Patients receiving striking benefit have been few and far between, and the incidence of side effects is high. About 17% of patients[17] will have minor complaints of nausea, vomiting, indigestion, and headache. In many cases these will subside spontaneously. However, there has been an appreciable incidence of more serious side effects, such as fever, arthralgia, dermatitis, granulocytopenia, hemolytic anemia, and so on. The dosage used varies somewhat and has to be individualized for the patient, but an average schedule might provide for a dose of 3 to 4 gm. daily for two weeks out of four. During acute episodes, as much as 1 gm. every three hours may be given.

Corticosteroids — Adrenal steroids are again not as effective here as they are in ulcerative colitis. Some surgeons[12] have thought that steroids increase the difficulty of operation, making the tissues more friable and increasing the incidence of postoperative complications. There also has been some evidence of progression of bowel pathology in association with the use of steroids, even during times of subjective improvement. Since regional enteritis is a chronic disease and likely to require long-term therapy, one hesitates to embark on the use of drugs with such serious long-term effects. Despite all of these facts, a trial of steroid therapy may be indicated if the patient does not respond to conservative medical therapy, especially if he is not a surgical candidate. Some authors consider corticotropin (ACTH) superior to the hydrocortisone derivatives, especially in the acute phases of the disease; they would give their patients 80 units of ACTH intramuscularly daily and slowly reduce the dose during a period of months. The patient can give himself the daily injections much as a diabetic administers his own insulin. Other authors think that there is no particular advantage in ACTH; they use oral steroids. Tapering of the dose should be done quite slowly, regardless of the preparation selected. Full remission may take months. It should be emphasized that hemorrhage and perforation seem to occur more frequently in patients taking steroids.

Nitrogen Mustard — Winkelman and Brown,[18] at the Cleveland Clinic, have used nitrogen mustard in 13 cases of complicated and uncomplicated regional enteritis. Their results have been encouraging so far: of 13 patients, nine had satisfactory responses. However, it should be stressed that this was only a preliminary report, and routine use of nitrogen mustard in the treatment of regional enteritis should await further trials.

Irradiation

Palliative radiation to the abdomen has been used for this illness since the late forties for early cases, free of complications. The rationale behind its use is that it has an anti-inflammatory effect. Be that as it may, it has not been strikingly effective. In one series of 69 patients having such mild enteritis, 24 did well, eight did reasonably well, and 37 either did not respond or got worse.[10] Further, the incidence of diarrhea and obstruction is said to be high after this procedure. Most institutions are not using radiation therapy at this time.

Surgery

Only 26 years ago Cutler[19] remarked that the best thing a surgeon could do for a patient with regional enteritis would be to return him, intact, to the care of his internist. Yet in most large institutions, about 85% of patients having regional enteritis now undergo operation at least once. This change in attitude reflects a sober optimism which seems justified in the light of current statistics. In 1963 Barber and associates[20] reported from the Mayo Clinic a 10-year follow-up of patients operated on for regional enteritis. Of the 88, 22 required additional operations. But what is significant is that, at the end of the 10-year period, the state of health of those who had required re-operation was the same as that of those who had not needed re-operation. Ninety per cent of *all* of the patients were either in good or fair health; however, three had died of the disease and one had died immediately postoperatively. Statistics such as these may allow us a sober optimism when we refer patients with regional enteritis for operation.

Table 3 shows the indications for operation in two series of cases, 561 in all. In essence, the indications for operation are simply those complications of regional enteritis which cannot be treated medically. Duodenal ulcer was coincidental in those cases in which it was associated with the regional enteritis. The incidence of duodenal ulceration is no higher for patients having regional enteritis than for the population as a whole.

The operative procedure of choice in most experienced hands[12,21] seems to be

primary resection of the affected region, preserving as much colon as possible. In previous years by-pass procedures were in vogue; but since the operative mortality for both procedures is now the same, there seems to be no valid reason to perform a by-pass operation in most cases. Most surgeons now prefer to excise and remove diseased bowel rather than allow the intestinal fluid to be routed around it.

The improved mortality rate (less than 2%)[12,21] probably has resulted in large part from improved techniques in the preoperative preparation of the patient. Before operation, anemia, electrolyte imbalance, and dehydration should be corrected. If the patient is febrile, broad-spectrum antibiotics may be given.

Recurrences usually occur within two years of operation, but it may be as long as 20 years before some recurrences are seen. Just what constitutes a recurrence is a moot question that colors statistics. It should be taken for granted that someone who has had an extensive resection of small intestine may have a little diarrhea without the disorder being called a recurrence; further, the radiologic picture of a patient having had such a procedure may be a little more difficult to interpret than that of a normal person. If one then applies the criteria that mild diarrhea alone does not constitute a recurrence and that a mildly positive roentgenogram does not determine the existence of a recurrence in the absence of clinical confirmation, then the recurrence rate may be quoted as 35%.[3,12,20,21] About half of recurrences will be controlled by operation and half by medical measures. Finally, of the 18% who come to a second operation, about half will need a third procedure.

Whenever recurrent disease is present, the treatment of choice is medical, and operation should be offered only in the face of intractable complications.

Conclusion

In conclusion, then, what can we expect to happen to our patient with regional enteritis? If he has acute regional ileitis, he has a 50% to 90% chance of recovering completely and of having no recurrences. If he has any of the other forms of enteritis, he has about a 10% chance of doing well on medical treatment alone. On the other hand, he has about a 10% chance of dying either of his disease or because of operation for it. He has about an 80% chance of being operated on at least once, an 8% chance of needing only two operations, and a further 8% chance of needing three or more operations. And even if he is operated on, he has a 20% chance of having a recurrence, controlled at least reasonably well without operation.

Thus, in this disease, while the mortality is becoming acceptable, the morbidity remains frightening.

Clinical Path Conference

Liver and Kidney Failure in a 45-Year-Old Housewife

A 45-year-old housewife was admitted to St. Barnabas Hospital on May 7, 1966, with a one-week history of anorexia, nausea, and vomiting. For at least two weeks, she had become increasingly jaundiced and had noted enlargement of her abdomen. She had been in good health until four months previously when an attack of "flu" forced her to bed for two weeks. Before her "flu" attack, she had had periodic episodes of mild, colicky abdominal pain usually associated with ingestion of pork chops or fatty foods.

The patient denied contact with jaundiced persons, had not received recent transfusions or injections, and was not taking drugs. She used carbon tetrachloride occasionally in her housework but could recall no recent exposure. Until a month before her final illness, she had consumed a moderate quantity of alcohol and then stopped drinking "on her own."

The patient was a deeply jaundiced, asthenic white female. Her blood pressure was 130/80, her pulse 120 and regular, and her temperature 100°. The skin showed no angiomata. Except for tachycardia, the heart examination was normal. The lungs were clear to auscultation and percussion. A tender liver was palpated 10 cm. below the right costal margin; the edge was smooth and firm. The tip of the spleen was palpable. The abdomen was distended, but no fluid wave was elicited, and the bowel sounds were normal. No peripheral edema was observed. The lungs were clear to auscultation. The hands exhibited a fine tremor.

The laboratory data on admission showed a hemoglobin of 10.5 gm.%, a white blood cell count of 23,000 with 72 mature neutrophils and 23 band forms, and a sedimentation rate of 85 mm/hour. Studies related to the liver included a total bilirubin of 20.5 mg./100 ml. with a one-minute value of 15.1 mg./100 ml., a 4+ cephalin flocculation, a thymol turbidity of 3.5 units, a total protein of 5.9 gm.% with an albumin of 2.0 gm.% an alkaline phosphatase of 24 K-A units, a SGOT of 81 units, a LDH of 130 units (normal less than 100 units), a cholesterol of 173 mg./100 ml., and a prothrombin time of 22 seconds (control 14 seconds). Other serum values were a BUN. of 11 mg./100 ml., sodium of 126 mEq/l, chloride 91 mEq/l, potassium 3.0 mEq/l, and amylase 62 units. The urinalysis showed a specific gravity of 1.018, a 2+ albumin, a 4+ bilirubin, a negative urobilinogen, a positive urobilin, and 2-4 WBC/hpf.

X-ray studies — chest films, upper gastrointestinal studies, and barium enema — showed only an enlarged liver.

The patient did not improve and continued to have nausea and vomiting. An indwelling nasogastric tube returned clear gastric contents. A low grade fever of 99 to 101 degrees continued, and her pulse fluctuated between 90 and 120.

On May 12, the fifth hospital day, she underwent a laparotomy. Following the operation (a cholecystectomy and liver biopsy), her jaundice increased in intensity, and the serum bilirubin climbed to 30 mg./100 ml. Her fever persisted despite streptomycin and penicillin therapy, and the white blood cell count fluctuated between 20,000 and 30,000. Her abdomen became more distended. In addition, her BUN. began to increase. By May 23, the BUN. was 77 mg./100 ml. and on May 24, it reached a peak of 117 mg./100 ml. On May 26, she vomited coffee ground material, passed black stools, became hypotensive, and died.

Continued

Differential Diagnosis

Dr. Frank Martin*

Before I discuss the differential diagnosis, I have two questions. What was her mental state before death, and was the prothrombin time of 22 seconds repeated after giving Vitamin K?

Dr. Reece

Her mind was clear until the day of death. The prothrombin time was not repeated, and Vitamin K was never given.

Dr. Martin

We have a middle-aged woman who was in good health until four months before coming into the hospital. She says she consumed a moderate quantity of alcohol. I will assume this was an understatement.

She used carbon tetrachloride — a piece of historical information I will consider and then dismiss from the differential at the onset. The jaundice caused by carbon tetrachloride occurs within days or even hours after exposure. Decreased renal function and mental symptoms are noted immediately. The patients recover or die within a short time and do not have a two-month course as did this patient.

Physical Examination

Physical examination yielded two important observations — an enlarged liver and a palpable spleen. Both are often seen in hepatocellular diseases. An enlarged liver is uncommon in jaundice due to obstruction, but it is present in 30-50% of patients with cirrhosis and in a lesser percent of patients with hepatitis. A palpable spleen in a patient with jaundice is an important observation. I presume one can see a large liver and a large spleen in a patient with hemolytic anemia and jaundice but, for the most part, this is a sign of hepatocellular disease. The liver was definitely enlarged. It was down 10 cm., and it was abnormal because it was firm. The normal liver will have a smooth surface and may have a sharp edge, but it is not firm. A large firm liver in the presence of a palpable spleen makes me suspicious of hepatocellular disease.

I will go directly to the liver function tests. The bilirubin is that of obstructive jaundice. The one-minute value was 15 mgm.% with a total bilirubin of 20 mgm.%. The 4+ cephalin floculation is significant. It is a sensitive test which is positive in 80-90% of patients with marked hepatocellular disease. The thymol turbidity was normal. This doesn't rule out hepatocellular disease and, in perhaps 50% of patients with cirrhosis, it will be normal.

The next finding is of paramount importance — a total protein of 5.9 gm.% with albumin of 2 gm.%. It is significant because there are few causes of a marked decrease in albumin. In this country these are, in order of frequency, cirrhosis, glomerulonephritis, and perhaps multiple myeloma. Starvation can do the same thing, but for practical purposes a low albumin in a patient with jaundice is strong evidence of severe hepatocellular disease.

The SGOT was 81 units. This is not helpful to me. If it had been 1000 units, it would have been almost diagnostic for hepatitis, but an elevation of 81 units can be seen in either obstruction or cirrhosis. The LDH is given as 130 units. I really don't think that this test has much advantage over the SGOT, even though it is said to be more specific for liver damage. The prothrombin time of 22 seconds with a control of 14 seconds indicates severe hepatocellular disease, especially since it did not return to normal after the giving of Vitamin K.

---

*Attending Internist, St. Barnabas Hospital.

History

At this point I would like to return to the history. Episodes of mild colicky abdominal pain associated with ingestion of pork chops and fatty foods are characteristic of gallbladder disease with stones. If a gallbladder is distended with a balloon at surgery, the patient has a sensation of fullness or a deep sense of discomfort but not colicky pain. He does not become nauseated or have vomiting. On the other hand, if the biliary tree is distended, nausea, vomiting and colic develop. In colic, stones are usually causing partial or complete duct obstruction. It is true that a cholecystitis can occur without stones. Perhaps this is due to a mucous plug with increased pressure in either the biliary or cystic duct. Colicky pain in cholecystitis without stones is rare.

Portal Cirrhosis vs. Postnecrotic Cirrhosis

Let us consider the patient before surgery with the information we have. First, a reasonable certainty of severe hepatocellular disease exists. Secondly, common duct obstruction and stones are probably causing the obstruction. As for the type of hepatocellular disease, portal cirrhosis is the most likely by all odds. Much has appeared in the literature lately about post-necrotic cirrhosis. Personally I don't know whether or not this is a definite entity apart from Laennec's cirrhosis. Clinically I don't think they can be differentiated. Perhaps there is a greater statistical incidence of alcoholism in portal cirrhosis and more hepatitis before post-necrotic cirrhosis, but statistics don't always help in managing patients.

The physical findings in both diseases are basically the same. One thing I don't understand about post-necrotic cirrhosis is that in most series, the number of palpable livers is given at about the same rate as cirrhosis, namely about 75%, but at autopsy the majority of post-necrotic livers are smaller. Why this discrepancy I do not know. From a clinical standpoint I can't differentiate these two types, if indeed they are different. Pathologically, I'll leave it up to the pathologist to describe the difference between the two. This is not an acute hepatitis. The liver function is too abnormal, especially the albumin of 2 mg.%. The globulin fraction is also helpful in separating cirrhosis from a prolonged hepatitis. The gamma globulin is more consistantly elevated in cirrhosis.

Indications for Surgery

In my opinion surgery was mandatory in this patient. I say that because I am convinced stones were present. If one leaves a common duct obstruction unrelieved, the liver function will degenerate, and it will degenerate much faster in an already impaired liver. The operation, however, should be done under local anesthesia. Using general anesthesia in the presence of marked liver dysfunction is a great risk. Also, certain types of analgesics are more dangerous than others, and those detoxified by the liver are the riskiest. Morphine is probably the worst offender. It is detoxified al-

Continued

most completely by the liver. In patients with severe cirrhosis, a small amount of morphine can act over a very prolonged period. Demerol, on the other hand, is excreted primarily by the kidneys and is safer. Long-acting barbiturates are excreted primarily by the kidneys and are safer than the short-acting ones which are detoxified by the liver. Paraldehyde is another offender; it is broken down almost exclusively by the liver and is dangerous in the presence of liver dysfunction.

This patient should have had surgery, but it should have been done under local anesthesia. The risk of leaving a common duct obstruction unrelieved is greater than the risk of operating in the face of hepatocellular dysfunction.

Hepatorenal Failure

The rise in the bilirubin after surgery is an ominous sign. Her fever persisted despite streptomycin and penicillin, and the white blood count was elevated. The white count of 20,000 was not necessarily due to infection — such as cholangitis. It was consistent with severe hepatic failure. A rising BUN. in the presence of hepatocellular disease portends disaster.

Baldus *et al.* wrote an excellent review of liver dysfunction with renal dysfunction in the March 1964 *Annals of Internal Medicine.*[1] They studied 25 patients with hepatic insufficiency who developed uremia. Nineteen of those 25 died. Why the combination is fatal is not known. They believe there is an impairment of the renal hemodynamics. Azotemia occurs before oliguria and before diminution in concentrating ability. In other words, the volume and specific gravity of the urine remain normal in the early phases of the azotemia. When oliguria does occur, the inability to concentrate may become impaired. One of two things must be happening: either there is more urea being formed or there must be an increased re-absorption of the urea from the kidneys. The latter seems most likely.

I think of liver diseases in terms of metabolic abnormalities. The liver is certainly the most metabolically important organ in the body. It is essential in the intermediary metabolism of all three basic substances, namely, carbohydrates, proteins, and fats. It is responsible for the synthesis of proteins, and it forms greater numbers of enzymes. The liver affects the intracellular metabolism of every cell in the body. As the liver dysfunction grows, nearly every cell in the body is impaired. Some organs are more sensitive to these changes than others — such as the brain and the kidneys. It seems to me what really happens is that the metabolic function of the kidney is impaired by liver dysfunction, that urea is reabsorbed, and that azotemia develops.

This patient did not go into liver coma. This does not mean she did not have severe liver failure. To be sure, coma is common in hepatic insufficiency. Clinically, there are several phases patients go through. They become euphoric, untidy, and slow down mentally. As time goes on, they become confused and stuporous but can be aroused. Finally, they cannot be aroused, and that, by definition, is hepatic coma.

There are many explanations for hepatic coma. Certainly ammonia can cause hepatic coma, but there are different types of hepatic coma, and ammonia-induced coma is just one type. In some patients with portal caval shunts, ammonia intoxication with flapping tremors is common. Patients who go into this type of coma often recover with therapy. I know one patient who went into 15 coma episodes and recovered from each. In his final episode the blood ammonia was not particularly elevated and he died.

On the other hand, I have never seen a recovery in patients in coma from acute yellow atrophy. They seem to have a metabolic abnormality in the brain. Coma is a grave sign. The vast majority do not recover.

Cholangitis

An ascending cholangitis with cirrhosis is a possible explanation for this patient's problems. She had fever, but usually in cholangitis both chills and fever exist. Chills, fever, increasing jaundice with pain are characteristic. It is entirely possible that this patient also had a cholangitis or one of its complications such as a liver abscess. Whether or not cholangitis was present, I am certain severe hepatocellular disease, probably cirrhosis, was present and that the uremia was related to the hepatocellular disease. She finally vomited coffee ground material. In the majority of patients we think that hemorrhage is due to ruptured varices, but other bleeding sites may be the culprit. In two of the patients in the series of Baldus et al., terminal hemorrhage was not related to varices.

In conclusion, I believe that this patient had severe hepatocellular disease; that it was most likely a form of cirrhosis; that there were stones present; that the patient died of liver dysfunction; that she may have had cholangitis. Cholangitis certainly cannot be ruled out, but I don't feel that it in itself was the main cause of death.

Dr. Frank Martin's Diagnoses

1. Severe hepatocellular disease, probably secondary to portal cirrhosis.
2. Cholelithiasis with possible cholangitis.
3. Hepatorenal syndrome (clinical).

Comments

Dr. Reece

You didn't mention the alkaline phosphatase of 24 K-A units or the cholesterol of 173.

Dr. Martin

The alkaline phosphatase of 24 K-A units suggests an obstructive type of jaundice. The cholesterol can be elevated in obstructive jaundice, but it was perfectly normal in this patient. With extensive liver damage, the synthesis of cholesterol is retarded, and it will not be elevated. It is uncommon to see the alkaline phosphatase elevated this high in cirrhosis. A superimposed cholangitis would account for the elevation. Dr. Hay, I said that colicky pain was good evidence of increased biliary or cystic duct pressure. Do you agree with that?

Dr. Lyle Hay*

I agree. She probably did have stones. But this patient bothered me because she was said to have had the flu. Patients with influenza can have intestinal symptoms with colic and with reference of pain to the right upper quadrant.

It is very important in these patients to get liver function tests early rather than to wait for several weeks. If you have a patient with severe liver damage from biliary tract obstruction, biliary cirrhosis or biliary

---

*Surgery Department, St. Barnabas Hospital.

Continued

damage takes time to develop. In this patient with a four-week history of jaundice, the degree of her liver damage is more severe that that caused by common bile duct obstruction. I have seen patients who have had obstruction for six weeks without this degree of liver damage.

Patients with carcinoma of the pancreas and a progressive jaundice for four to six weeks do not show laboratory evidence of severe hepatocellular disease. These liver function tests were too abnormal to have come just from biliary tract obstruction. If you have cholangitis with a history of chills, fever, and toxicity; this process will be accelerated.

Dr. Harsharan Kaur*

Don't you think percutaneous cholangiographic study would be valuable in demonstrating obstructive process without resorting to surgery?

Dr. Hay

Liver biopsy or percutaneous cholangiography could have been used, but I agree with Dr. Martin that a liver biopsy under local anesthesia offers the most information at the least risk. You can directly visualize extrahepatic biliary tract and then do a cholangiogram.

Pathological Discussion

Dr. Reece

As Dr. Martin predicted, the autopsy showed severe liver disease. At operation the gallbladder contained stones. Fibrosis of the wall with round cell reaction was present. The extrabiliary channels were patent, and no stones were palpated in the common duct. The most striking observation was an enlarged, smooth, fatty liver. A Schleicher needle biopsy was done and showed a diffuse fatty infiltration (Figure 1). Numerous liver cells were replaced by fat, and I put forth a diagnosis of fatty metamorphosis.

I chose to call it fatty metamorphosis instead of portal cirrhosis with fatty change — although both were present. Fatty metamorphosis occurs more in young women alcoholics and is more rapidly fatal.[2] It is fre-

---

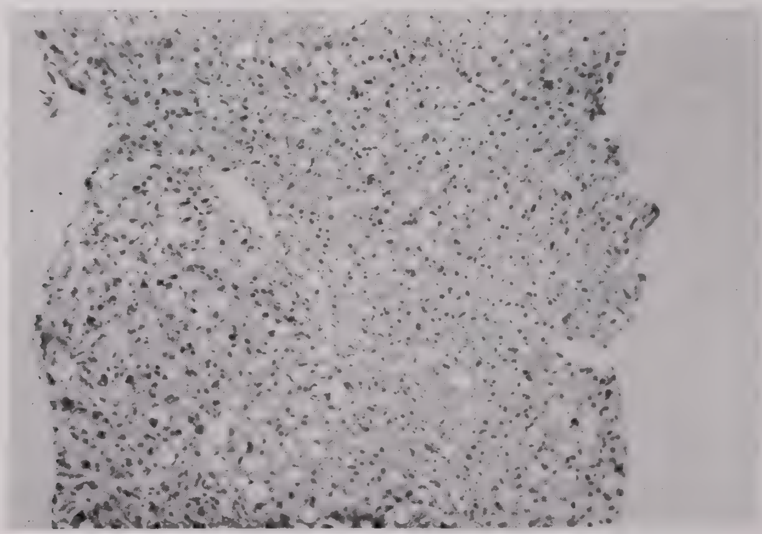

Fig. 1 — Schleicher needle biopsy of liver showing fatty change. H & E 35×

quently associated with right upper quadrant pain and with liver tenderness, and 25% of cases have leukocytosis. For mysterious and unknown reasons, many patients die with dyspnea and shock. Both fat emboli and hypoglycemia have been advanced as causes of death. Many of these patients present with a picture of obstructive jaundice and have an elevated alkaline phosphatase.

At autopsy we observed a deeply jaundiced, slender young woman. The lungs showed aspirated blood in the tracheobronchial tree, and the lower lobes were the seat of a necrotizing bronchopneumonia.

The liver weighed 2150 grams and was engorged with fat (Figure 2). The fatty changes were superimposed on a portal cirrhosis. Delicate bands of fibrous tissue linked the portal areas, and there was a minimal biliary duct proliferation. Inflammatory cells were few. There was no plugging of ducts with bile and no gathering of inflammatory cells around cholangioles. The spleen was enlarged and weighed 275 grams.

Whenever one deals with an alcoholic with cirrhosis, one must keep pancreatitis in mind. In this patient the pancreas was surrounded by fat necrosis, and the pancreatic parenchyma was pervaded by polymorphonuclear leukocytes and round cells (Figure 3). The incidence of pancreatitis in alcoholic patients varies from 20-60%.[3]

The kidneys weighed 250 grams. Each had a smooth bluish surface. Section of the kidney disclosed glomerular lesions which have been called "cirrhotic glomerulosclerosis" or "membranous and proliferative glomerulonephritis of cirrhosis."[4-5] It is characterized by hypercellular

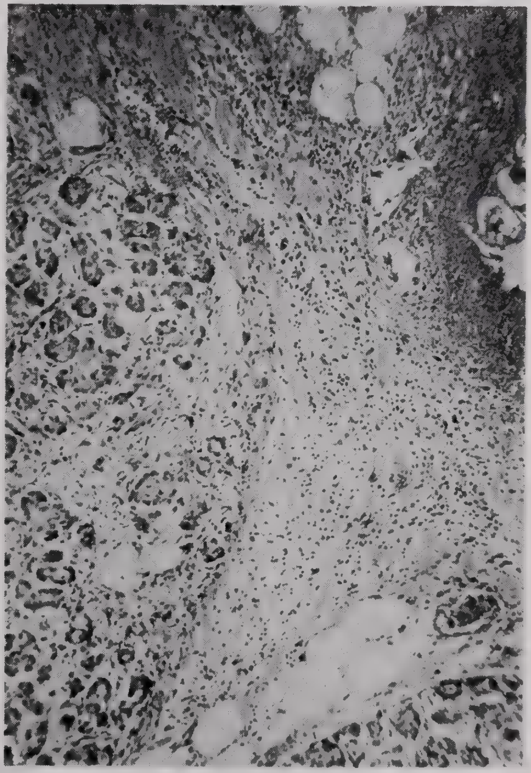

Fig. 3 — Edge of pancreas showing acute inflammatory cells and fat necrosis. H & E 35×

Continued

glomeruli and by thickening of the basement membranes (Figure 4). This change occurs in about 28% of terminal cirrhotics. It is not directly correlated with functional changes during life, and its meaning is uncertain.

A second lesion occurred in the tubules. The proximal tubules show diffuse degeneration which bordered on tubular necrosis (Figure 5). In the renal failure of cirrhosis, tubular changes may vary from mild tubular degeneration to necrosis. Similar tubular changes could be induced by hypokalemic, excessive osmotic load of sucrose and toxins, but I see no reason to evoke these causes. Although she had a low serum potassium, the tubule lacked characteristic vacuolar changes, and she did not put out dilute urine as patients do with hypokalemic nephropathy.

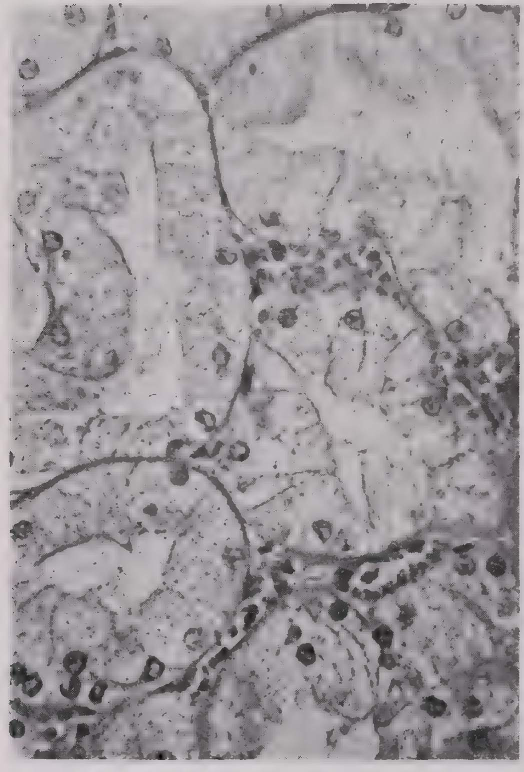

Fig. 4 — High-power view of proximal tubules showing degeneration of tubular epithelium. H & E 430×

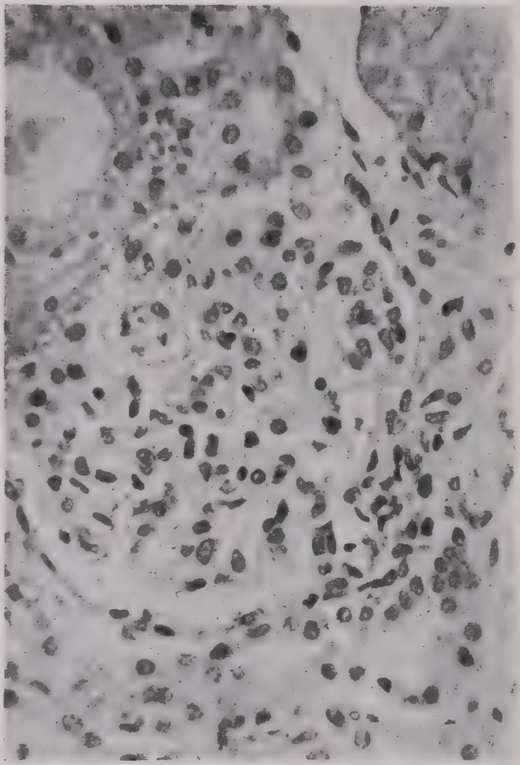

Fig. 5 — Hypercellar globerulus with capsular adhesion. H & E 430×

The hepatorenal syndrome is a legitimate term for describing combined liver and renal failure in terminal cirrhosis. It should not be used to describe liver and renal deterioration induced by toxins, by infection or by generalized sepsis and shock. The term "hepatorenal syndrome" was coined by surgeons. They noted that a certain group of patients developed oliguria and azotemia, with the preservation of otherwise good tubular function, after biliary tract surgery for obstructive jaundice.

This patient bled from an erosive esophagitis and gastritis. We did not find a ruptured varis, although she did have dilated submucosal veins (Figure 6).

Dr. Kaur

Do you think this patient would have done better if surgery had been

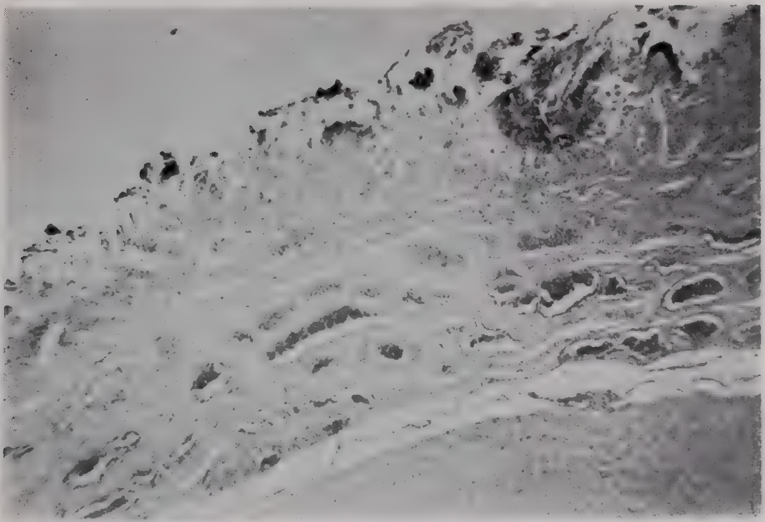

Fig. 6 — Erosive esophagitis with dilated submucosal veins. H & E 100×

delayed until the fatty cirrhosis was treated?

Dr. Hay

Yes, I had a young man who came in for a cholecystectomy with a similar history. He was a heavy drinker, and I palpated a big liver. He stopped drinking and ate well for three weeks, and then had his gallbladder out. At operation he still had fat in his liver. He had fever and jaundice after surgery, and his first three or four days were stormy. If we had operated on him three weeks before, he might not have survived the operation. I think he would have gotten over his fatty metamorphosis completely if we had just given him more time. If I had it to do over again, I would wait six to eight weeks before operating.

Final Anatomical Diagnosis

1. Portal cirrhosis with marked fatty change.
2. Acute pancreatitis with fat necrosis.
3. Bronchopneumonia.
4. "Glomerulonephritis of cirrhosis" and degeneration of proximal tubule epithelium.

Miltown®

An eminent role in medical practice

- Clinicians throughout the world consider meprobamate a therapeutic standard in the management of anxiety and tension.
- The high safety-efficacy ratio of 'Miltown' has been demonstrated by more than a decade of clinical use.

Miltown®
(meprobamate)

Indications: Meprobamate is effective in relief of anxiety and tension states. Also as adjunctive therapy when anxiety may be a causative or otherwise disturbing factor. Although not a hypnotic, meprobamate fosters normal sleep through both its anti-anxiety and muscle-relaxant properties.

Contraindications: Previous allergic or idiosyncratic reactions to meprobamate or meprobamate-containing drugs.

Precautions: Careful supervision of dose and amounts prescribed is advised. Consider possibility of dependence, particularly in patients with history of drug or alcohol addiction; withdraw gradually after use for weeks or months at excessive dosage. Abrupt withdrawal may precipitate recurrence of pre-existing symptoms, or withdrawal reactions including, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, the dose should be reduced and operation of motor vehicles or machinery or other activity requiring alertness should be avoided if these symptoms are present. Effects of excessive alcohol may possibly be increased by meprobamate. Grand mal seizures may be precipitated in persons suffering from both grand and petit mal. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side effects: Drowsiness may occur and, rarely, ataxia, usually controlled by decreasing the dose. Allergic or idiosyncratic reactions are rare, generally developing after one to four doses. Mild reactions are characterized by an urticarial or erythematous, maculopapular rash. Acute nonthrombocytopenic purpura with peripheral edema and fever, transient leukopenia, and a single case of fatal bullous dermatitis after administration of meprobamate and prednisolone have been reported. More severe and very rare cases of hypersensitivity may produce fever, chills, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, anaphylaxis, stomatitis and proctitis. Treatment should be symptomatic in such cases, and the drug should not be reinstituted. Isolated cases of agranulocytosis, thrombocytopenic purpura, and a single fatal instance of aplastic anemia have been reported, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity has been reported, usually after excessive meprobamate dosage. Suicidal attempts may produce lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Usual adult dosage: One or two 400 mg. tablets three times daily. Doses above 2400 mg. daily are not recommended.

Supplied: 'Miltown' (meprobamate) is available in two strengths: 400 mg. scored tablets and 200 mg. coated tablets. 'Meprotabs' (meprobamate) is available as 400 mg. white, coated, unmarked tablets. *Before prescribing, consult package circular.*

Bleeding Problems in Leukemia

OLE JERDE, M.D.
Medical Resident

HEMORRHAGE OF varying degrees is a frequent complication of leukemia and is generally a troublesome problem to the clinician treating the leukemic patient. While bleeding is generally associated with severe thrombocytopenia, it can occur at any platelet level. The purpose of this paper is to discuss various factors which may be involved in bleeding in the leukemic patient.

Causative Factors

Hemorrhage may be the initial manifestation of acute leukemia. Friedman et al.[1] reported on eleven confirmed and two probable cases of acute leukemia which presented with various bleeding problems ranging from easy bruisability to major hemorrhage. Boggs and his group,[2] in a series of 289 cases, found that cutaneous hemorrhages were present in 55 percent of the patients. Other series report bleeding problems present in 19 percent[3] and 47 percent[4] of patients at the time the diagnosis of leukemia was made.

Infection

Hemorrhage is a common cause of death in the leukemic patient and is second only to infection.[5] Hersh et al.[5], in a large series, reported massive hemorrhage to be present in 66.8 percent of their patients at autopsy. Since 1960 they have used platelet transfusions when indicated and have noted a decrease in fatal hemorrhage down to 38 percent. Hemorrhage was listed as the cause of death in 27 percent of Rivers' patients[3] and in 44 percent of Boggs' patients.[2] Acute promyelocytic leukemia seems to present a special problem, since the majority of deaths from that disease were attributed to hemorrhage.[6]

Disorders of bleeding may be classified as abnormalities involving the

vascular bed, quantitative as well as qualitative defects in platelets, deficiencies in plasma factors, fibrinolytic abnormalities, or a combination of the above.[7]

The Platelet Level

Thrombocytopenia* secondary to decreased megakaryocytes in the bone marrow is the most common cause of bleeding in leukemia.[2,5,7,8] Since serious bleeding rarely occurs at platelet counts greater than 60,000 per mm^3, the above authors have termed this the critical platelet level. Most bleeding problems will occur at platelet levels below the critical level; however, the frequency and extent of hemorrhage at a given platelet count is quite variable. Some patients may have severe hemorrhage at counts near the critical level while other patients with severe thrombocytopenia may have no bleeding difficulties.[1,9,10]

Few studies have been made attempting to correlate platelet levels with degree and frequency of hemorrhage. Graydos[8] reported on 92 patients, comparing platelet levels and hemorrhage with seemingly good correlation. He found that when platelet counts were less than 1,000 per mm^3 overt hemorrhage was present 92 percent of the time. With platelet counts between 50,000 and 100,000 per mm^3 hemorrhage occurred 8 percent of the time. Severe hemorrhage rarely occurred at levels over 20,000 per mm^3, while petechiae, ecchymoses and epistaxis were quite common at this level. Grossly visible bleeding decreased in frequency along with a rise in platelet count. Graydos also noted that a decrease in platelet levels occurred from two to four days before the onset of bleeding. He felt that hemorrhage probably resulted from the thrombocytopenia; however, subclinical bleeding might have produced the thrombocytopenia which then caused the grossly visible hemorrhage. He went on to state that perhaps both the hemorrhage and the platelet level might be influenced by some other factor.

Platelet Morphology

In Friedman's series[1] platelet function studies were performed because all patients had normal platelet counts in the face of overt bleeding. Abnormal results were found in the prothrombin consumption test and in the thromboplastin generation test, and most of the bleeding times were also prolonged. The platelets were then studied morphologically with light microscopy and the electron microscope. There were marked variations in size, ranging from small, dense, round forms to large, globular, balloon forms with dendritic formation. On the basis of his studies Friedman postulated that abnormalities in platelet function might well be an early manifestation of acute leukemia.

Thrombocytopenia and Hemorrhagic Diathesis

Intracranial hemorrhage is a common cause of death in the leukemic patient and is generally due to severe thrombocytopenia associated with a hemorrhagic diathesis. However, it may be associated with blast cell crisis, which is a rapidly rising peripheral white blood count in which most of the cells are blast forms.[11] Of 13 patients who had blast crisis of more than 300,000 white blood cells, nine patients died within a few days following this crisis. Platelet counts in these nine patients ranged from 8,000 up to

---

*See Test Your Word Score Page 1411.

205,000 per mm^3. At autopsy bleeding was found in the white matter of the brain. Tumor nodules were found which were surrounded by hemorrhage. It is felt that leukemic cells lodge in the blood vessels and infiltrate through the vessel walls into the surrounding tissues, causing necrosis of the vessel wall and predisposing to hemorrhage, even with normal numbers of platelets. The patients in this second group had less than 300,000 white blood cells per mm^3 and a smaller percentage of blast forms. Platelet counts in the second group ranged from 400 to 8,500 per mm^3. At autopsy bleeding was found to have occurred in either the subdural or the subarachnoid space and not in the brain substance as in the first group. In their series the blast crisis was an ominous sign, being associated with an immediate mortality rate of 60 percent.

Polysaccharide Level

Infection may be associated with a hemorrhagic tendency, the best known example being infection due to the meningococcus. Polysaccharides extracted from bacteria may inhibit the coagulation mechanism in a manner resembling heparin, which is a naturally occurring polysaccharide.[9] These authors studied polysaccharide levels in leukemic patients, most of whom had bleeding manifestations. Their studies indicated that bleeding rarely occurred if the platelet count was over 60,000 per mm^3 regardless of what the polysaccharide level was. Their studies also showed that most of the bleeding occurred in patients who had low levels of platelets and elevated levels of polysaccharides. There was no exact inverse relationship; however, these two factors appear to be independent and are additive or complementary in causing bleeding. While the anticoagulant effect of these polysaccharides may have been part of the problem, Freeman thought that vascular injury due to bacteria was more likely the mechanism. The vascular injury sequestered platelets in a patient who already had a borderline platelet level, decreasing the number of circulating platelets to where overt hemorrhage could occur. With appropriate antibiotic therapy bleeding ceased and the platelet counts gradually increased. In those patients in whom the infection could not be controlled, death was due to hemorrhage, overwhelming infection, or both.

Fibrinogen Metabolism

Another area concerns leukemia associated with abnormality in fibrinogen metabolism. As mentioned previously,[6] acute promyelocytic leukemia is characterized by severe hemorrhage, poor response to any therapy, and a rapid, short, progressive course. In Rosenthal's series[6] 10 of 17 patients expired during the first month, all but three dying of hemorrhage, either intracranial or gastrointestinal. Abnormal promyelocytes are the predominant cell in the bone marrow. These cells have immature nuclei along with different sized granules in their cytoplasm. These granules often have different staining properties. Platelet counts ranged from 10,000 to 60,000 per mm^3. Fibrinogen levels were low and varied from 40 to 170 mg. percent. Factor V levels were also decreased. Initially there was loose clot formation and poor trapping of red cells. Subsequently the clot contracted to a small firm size; there was no clot lysis. Because of the abnormal cells, in addition to the other deficiencies noted, Rosenthal preferred to call this "promyeloid" leukemia or "promyelocytic fibrinopathic" leukemia. One pa-

Continued

tient developed a hematologic remission with return of fibrinogen to normal levels.

Fibrinolytic Factor

Didisheim et al.[12] reported two patients with acute promyelocytic leukemia. Both cases had abnormal promyelocytes as the predominant bone marrow cell along with deficiencies of fibrinogen and factor V, and both patients developed hematologic remissions with improvement in the bone marrow along with return of fibrinogen and factor V to normal levels. Fibrinogen was given in an attempt to determine the etiology of the hypofibrinogenemia. Normally half of the amount given disappears from the circulation in four to six days; in this patient half was gone in 26 hours. Didisheim and his colleagues repeated the fibrinogen along with heparin; however, there was no change in the rate of disappearance. Occasionally coagulation time by the plastic tube method was less than normal. Fibrinolysins were not found. No thrombi were present at autopsy. They therefore concluded that acute promyelocytic leukemia is a distinct clinical entity.

Fibrinolysis has been reported in several different diseases including leukemia.[14,15] As described in Cooperburg's case,[14] the patient had symptoms of leukemia for about one month prior to admission, characterized by fatigability and occasional epistaxis. Petechiae and bleeding from the gums began four to five days prior to admission, with purpura and hematuria presenting on the day before admission. The fibrinogen on admission was 78 mg. percent. The patient expired during the first hospital day of massive intracranial hemorrhage. The clot formed normally but began to lyse in four hours and was complete in less than 24 hours.

Pisciotta[15] described a similar clinical picture with intracranial and gastrointestinal hemorrhage as the terminal event. Fibrinolysins were present for at least five days prior to death. Since fibrinolysin is also active against fibrinogen, prothrombin and factor V[14], a combination of these abnormalities, in addition to thrombocytopenia, readily explains the severe hemorrhage in the patients.

Defibrination Syndrome

The defibrination syndrome is well known and, while rare, has been observed in acute leukemia. Baker[13] reported a case of acute myeloblastic leukemia with widespread hemorrhage and a total clinical course of 20 days. Abnormally low levels of fibrinogen, plasminogen, and factor V were found. Heparin was given with cessation of bleeding along with improvement in the patient's sensorium. The fibrinogen, plasminogen, and factor V levels concurrently increased. Bleeding, however, occurred again two days later and the patient expired. Widespread intravascular clots were present at autopsy. The authors suggested that the leukemic cells may have had an effect on the increased coagulation.

Summary

1. Thrombocytopenia is the most common cause of hemorrhage in acute leukemia.
2. Deficiencies of various factors and functional platelet abnormalities, in addition to fibrinolysin, are probably more common in leukemia than is generally recognized.

Case Report

A 53-year-old white male was admitted on January 5, 1966, with complaints of mild anorexia, weakness, fever and epistaxis for approximately six weeks prior to admission.

Physical examination revealed a fundal hemorrhage on the right side, a harsh systolic murmur, and a palpable liver.

Admission hemogram showed 6.7 gm. percent hemoglobin; wbc. 800 with 16 percent neutrophils, 78 percent lymphocytes and 6 percent monocytes. Prothrombin time ranged from 13.2 to 18 seconds. Lee White clotting time was 17 minutes. An initial bone marrow biopsy was abnormal but nondiagnostic. A repeat bone marrow three days later was diagnostic of acute myelogenic leukemia. Megakaryocytes were decreased. The patient was treated with prednisone, 6-Mercaptopurine, Vincristine and Methotrexate; however, there was no response to therapy. He required two to three units of blood daily to maintain an adequate hemoglobin. Platelet counts were always less than 10,000 per mm.^{3} Stools were positive for blood on admission and became tarry after the first week. He developed subcutaneous hemorrhages which were confluent over his back. He expired on 1/25/66. An autopsy was not done.

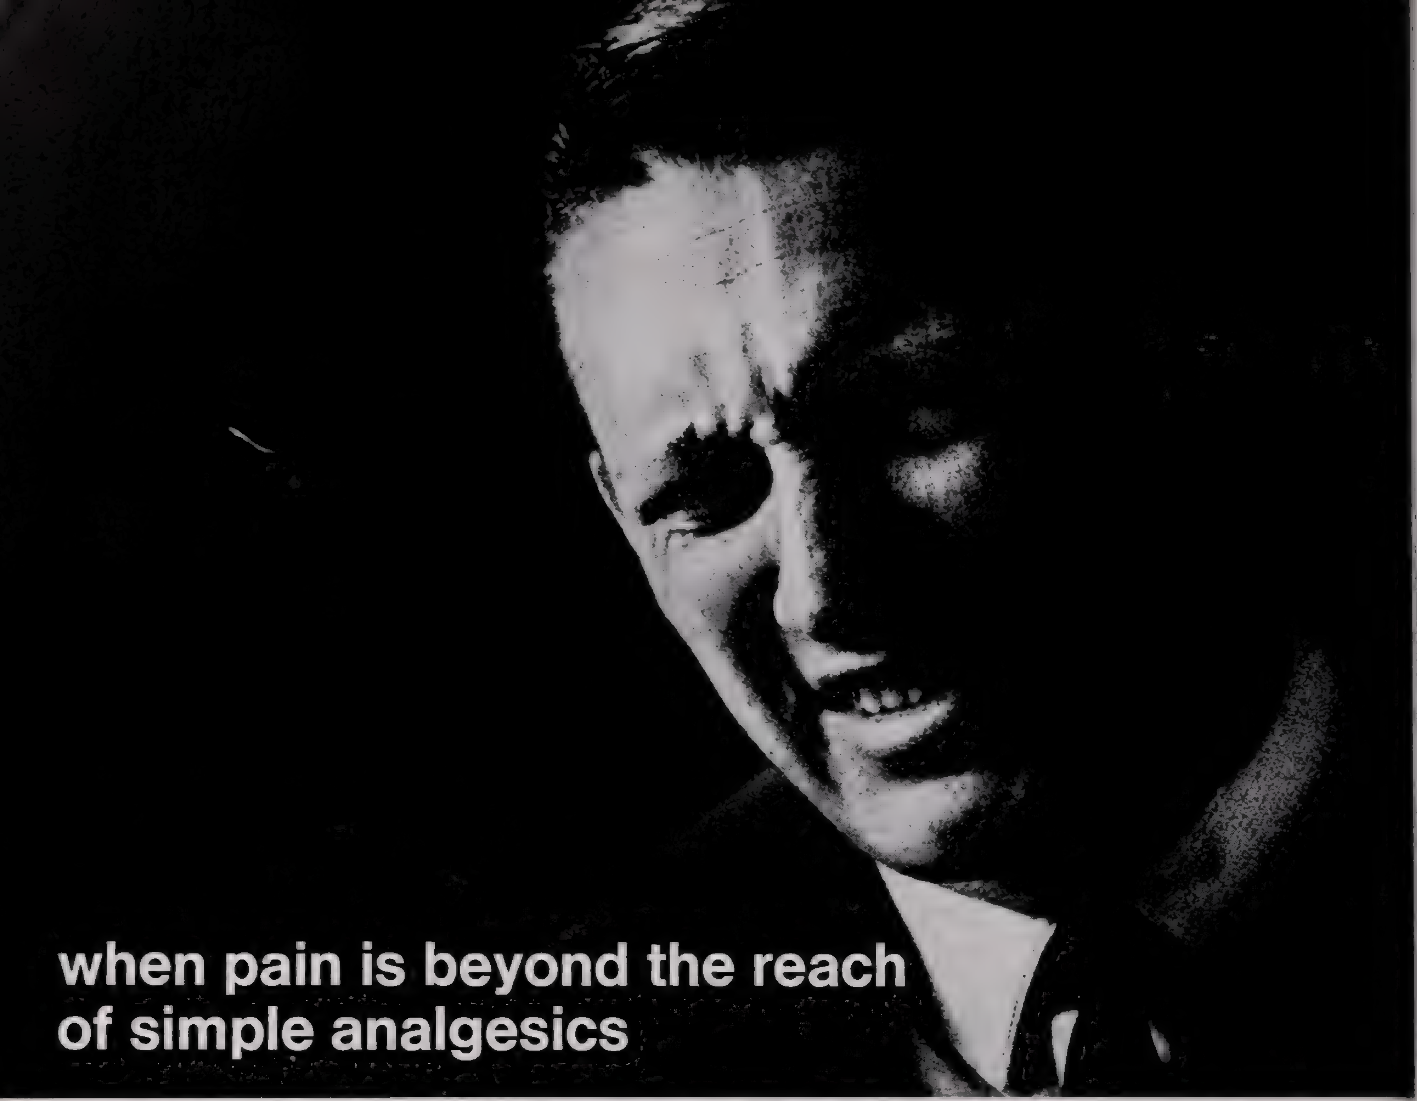
For Whom the Doctor Comes

It is not only for the sick man, it is for the sick man's friends that the Doctor comes. His presence is often as good for them as for the patient, and they long for him yet more eagerly. How we have all watched after him! What an emotion the thrill of his carriage-wheels in the street, and at length at the door, has made us feel! How we hang upon his words, and what a comfort we get from a smile or two, if he can vouchsafe that sunshine to lighten our darkness! . . . Over the patient in the fever, the wife expectant, the children unconscious, the Doctor stands as if he were Fate, the dispenser of life and death. . . . One can fancy how awful the responsibility must be to a conscientious man, how cruel the feeling that he has given the wrong remedy, or that it might have been possible to do better; how harassing the sympathy with survivors, if the case is unfortunate — how immense the delight of victory — William Makepeace Thackeray (1811-1863)

Triple-Faced

To the sick man, the physician when he enters seems to have three faces, those of a man, a devil, and a god. When the physician first comes and announces the safety of the patient, then the sick man says: "Behold a god or a guardian angel." — John Owen (1647)



when pain is beyond the reach
of simple analgesics

In the management of mild to moderate pain, give your patients comprehensive relief. TRANCO-GESIC extends the range of usefulness of aspirin by dimming pain perception—and *also* reducing mental and muscle tension.

TRANCO-GESIC® tablets

chlormezanone 100 mg. with aspirin 300 mg.

subdues the major contributors to pain:

- pain perception
- mental tension
- muscle tension-spasm

TRANCO-GESIC is so well tolerated it can be prescribed for anyone who can take aspirin. It is non-narcotic, and free from dangers of addiction, habituation, or dependence. TRANCO-GESIC is effective in all types of mild and moderate pain. Of 862 patients who were treated with chlormezanone and aspirin for various disorders, 88% reported excellent or good pain relief.[1]

Side effects have been minor. Occasionally gastric distress, weakness, sedation or dizziness occur. Reversible cholestatic jaundice has been reported on rare occasions. However, in 4,653 patients treated with chlormezanone, 97.7% had *no* side effects.[1] *Contraindication:* just one: sensitivity to aspirin. *Dosage:* Adults, usually 2 tablets three or four times daily. Children (from 5 to 12 years), 1 tablet three or four times daily.

Advances

Antibacterial Management of Infection Due to Gram-Negative Bacilli *

Part V. Some Infections of the Bloodstream, Cardiovascular System, Gastrointestinal Tract, Urinary Tract and Reproductive System

WILLIAM J. MARTIN, M.D.**
Rochester, Minnesota

Bacteremia

BACTEREMIA DUE to gram-negative bacilli is most commonly caused by members of the Enterobacteriaceae.[1-4] *Escherichia coli* organisms are responsible twice as often as are *Klebsiella-Aerobacter* organisms, and the remaining cases are most commonly due to *Proteus* organisms. Other possible pathogens of this group include *Paracolobactrum, Alcaligenes, Salmonella,* and *Shigella.* Bacteremia due to gram-negative bacilli not classified as Enterobacteriaceae and not causative of specific diseases may be caused by *Pseudomonas, Bacteroides, Haemophilus,* and *Achromobacter* organisms. As indicated previously, in serious infections due to these bacilli, empiric therapy with streptomycin and a tetracycline or kanamycin and chloramphenicol has been preferred. When microbiologic studies are complete, the empiric regimen is re-evaluated accordingly. For example, if *Pseudomonas* is identified as the pathogen, polymyxin B or colistin is substituted; if the patient has not done well and *E. coli* is reported as being susceptible to ampicillin and cephalothin on in-vitro testing, one of these drugs may be given to replace the empiric regimen.

In bacteremia due to either *B. fragilis* or necrobacilli, a tetracycline suffices. In bacteremia due to other organisms in the family of *Bacteroides* such as fusospirochetes or *Streptobacillus moniliformis,* penicillin is preferred.

Bacteremia due to *H. influenzae* is of higher incidence in children and has responded to streptomycin and a tetracycline, and also to chloramphenicol. Use of ampicillin or cephalothin warrants further investigation.

The drug of choice in typhoid fever currently appears to remain chloramphenicol.

In bacteremic brucellosis, streptomycin and a tetracycline given for two weeks are recommended; if only a tetracycline is given, there may be an appreciable incidence of relapse and perhaps an increased likelihood of brucellosis occurring at a later date unless the duration of therapy is considerably prolonged.

Of the bacteremias caused by *Pasteurella* organisms, tularemia responds to either streptomycin or a tetracycline. The same drugs are used conjointly in plague, but in bacteremia due to *P. multocida,* penicillin is preferred.

In bacteremia due to members of the tribe Mimeae, a tetracycline plus kanamycin, polymyxin B, or colistin is used at least until in-vitro susceptibilities are reported.

Patients with bacteremia due to *Vibrio fetus* are treated with streptomycin and a tetracycline.

Some Infections of the Cardiovascular System

Endocarditis and endarteritis[5] due to gram-negative bacilli have been relatively

Continued

---

*The six parts of this paper were presented, in part, at the Symposium on Antibacterial Agents sponsored by the Southern California Society of Hospital Pharmacists, Los Angeles, California, May 2, 1965.

See Part IV. Minnesota Med 49:1309, 1966.

**Mayo Clinic and Mayo Foundation: Section of Medicine.

uncommon, but their incidence is believed to be increasing. After in-vitro susceptibilities are reported and if empiric therapy is unsatisfactory, ampicillin, cephalothin, polymyxin B, or colistin may have application. If the bacilli are sensitive to tetracycline or chloramphenicol, use of the agent is sometimes continued; but another agent to which the organisms are sensitive, such as colistin, should be given, since endocarditis and endarteritis require a regimen with a bactericidal effect. The regimen should be evaluated by means of serum bactericidal tests; and if the patient's serum containing the given antibiotics, when diluted 1 to 4, has an eradicative effect in vitro on the pathogen treatment, the regimen is continued for at least four weeks. *Pseudomonas* infection is most likely to occur after cardiovascular surgery, and a regimen including polymyxin B or colistin is recommended; but cure is not usual unless further operation can remove the nidus of infection. Endocarditis due to *H. influenzae or H. parainfluenzae* might require streptomycin-tetracycline therapy, or conjoint use of chloramphenicol and a bactericidal drug, such as ampicillin or cephalothin. Brucellar endocarditis is extremely rare, but streptomycin and a tetracycline are indicated. In endocarditis due to Mimeae, a tetracycline plus kanamycin, polymyxin B, or colistin is given, at least until in-vitro susceptibilities are known.

Suppurative pericarditis is more often due to coccal organisms but is rarely caused by gram-negative bacilli, including *P. tularensis*. Combined streptomycin-tetracycline therapy is used in tularemic pericarditis.

A cryptogenic* or primary mycotic aneurysm refers to the growth of organisms, usually *Salmonella* organisms or staphylococci, on an arteriosclerotic site resulting in suppurative arteritis which may progress to rupture. This variety occurs in older people in the absence of endocarditis; by contrast, the embolomycotic variety associated with bacterial endocarditis is usually due to streptococci. Surgery plus empiric antibacterial therapy are indicated; preoperatively, cephalothin may provide antibacterial coverage. After operation, therapy in keeping with in-vitro susceptibilities is given in an attempt to preserve the integrity of the arterial prosthesis.

Some Infections of the Gastrointestinal Tract

Fusospirochetal gingivitis may progress to stomatitis wherein the cavity is covered with ulcers underneath a pseudomembrane. Penicillin is preferred, but a tetracycline also is effective.

The Liver

Pyogenic liver abscesses usually are due to *E. coli* organisms, staphylococci, or streptococci, including enterococci; sometimes anaerobic organisms, such as *Bacteroides* and rarely *Brucella* organisms, are causative. Empiric regimens like streptomycin-tetracycline-nafcillin or kanamycin-chloramphenicol-penicillin provide "coverage" until microbiologic data are known. The latter regimen, because of its inclusion of penicillin G would likely have a more efficient anti-enterococcal effect. Since the tetracyclines are more concentrated in the bile than is chloramphenicol, they may be preferable in these and related infections. Hepatic photoscans may identify the abscesses before operation and also provide more objective follow-up.

Suppurative cholangitis usually reflects biliary obstruction due to stone, scar, or tumor. "Coverage" as suggested for pyogenic liver abscesses is given until microbiologic data are known.

The Gallbladder

In acute cholecystitis, similar "coverage" is given until the patient is afebrile at least 72 hours. Cholecystography is performed about one week after subsidence of symptoms and if the sedimentation rate of erythrocytes has begun to return to normal. When the gallbladder is not visualized, the study is repeated in six weeks. Repeated failure to visualize the organ or the finding of stones indicates the need for surgery.

The Peritoneal Cavity

Peritonitis after various intra-abdominal catastrophes or surgery also is often managed initially by such regimens as streptomycin-tetracycline-nafcillin or kanamycin-chloramphenicol-penicillin. It is obvious that peritonitis, like certain of the hepatobiliary infections mentioned previously, may be difficult to study microbiologically, and hence antibacterial therapy may necessarily be empiric. If the abdominal cavity is surgically explored, cultures of peritoneal fluid or tissue may allow substitution of a more definitive regimen. In most cases, peritonitis is due to a mixture of organisms including Enterobacteriaceae, *Bacteroides* and enterococci, and of course the possibility of *Clostridium* organisms should not be neglected. Blood cultures should always be obtained, as these may provide etiologic information as well as aid in gauging the extent of the bacterial invasion.

---

*See Test Your Word Score Page 1411.

Gastroenteritis

Gastroenteritis from *Salmonella* organisms is managed by agents with systemic effect such as a tetracycline, chloramphenicol, and ampicillin, or by agents which are not well absorbed from the intestinal tract, such as paromomycin, neomycin, kanamycin, polymyxin B, and colistin, in keeping with cultural and in-vitro inhibition studies. However, since *Salmonella* infection may be associated with bacteremia and such complications as meningitis, pneumonia, and osteomyelitis, the agents with systemic effects may be preferable initially until more definitive microbiologic data are available. It should be recalled that *Salmonella* organisms are not uncommonly isolated from the urine of patients with gastroenteritis, especially women, and that use of antibacterial agents which are poorly absorbed on oral administration would not affect their urinary eradication.

There are data suggesting that antibacterial therapy of gastroenteritis from *Salmonella* organisms, by interfering with the function of the intestinal flora, prolongs the period during which stool cultures remain positive for *Salmonella* organisms.

Chronic hepatobiliary salmonellosis may be the essential problem in some persons having the carrier state. When the patient has gallstones, antibiotic therapy without cholecystectomy is often unsuccessful. Ampicillin and cephalothin are under investigation, but other regimens such as large doses of penicillin G, kanamycin, and colistin have been used with success. *Salmonella* organisms may also lodge in liver, bone, the urinary tract, aneurysms, the heart valves, and other sites. In cases of accessible areas of localized salmonellosis, surgical drainage is often diagnostically as well as therapeutically helpful.

Dysentery from *Shigella* organisms may respond to the sulfonamides, but in areas characterized by resistant strains, a tetracycline, ampicillin, or cephalothin may be preferable. *Shigella*, unlike *Salmonella*, rarely invades the blood, but about 50 cases of bacteremia from *Shigella* have been reported and this possibility at least warrants consideration. Furazolidone, neomycin, kanamycin, polymyxin B, or colistin sulfate given orally also may have use in nonbacteremic patients.

As aforementioned, it is disputed whether anti-bacterial agents such as the tetracyclines are useful in cholera. In this regard, World Health Organization reported a total of 81,400 cases of cholera throughout the world in 1964, representing an approximate increase in incidence of 20% over the total for 1963. The incidence of cholera is relatively high in Vietnam, particularly in Saigon.

Diverticulitis

Diverticulitis coli requires therapy active against Enterobacteriaceae and enterococci. In mild diverticulitis, a nonabsorbable sulfonamide like sulfaguanidine may suffice. Pericolic abscess may complicate severe diverticulitis, which may perforate and cause peritonitis. Regimens such as streptomycin-tetracycline-nafcillin or kanamycin-chloramphenicol-penicillin G provide "coverage"; but surgery, immediate or ultimate, has been required in 5 to 20% of patients. Surgery may also be required in certain complications (perforation, abscess, stricture) or when repeated attacks of acute diverticulitis occur.

Diarrhea due to enteropathogenic strains of *E. coli* and sometimes *Proteus*, *Klebsiella-Aerobacter*, and *Pseudomonas* organisms occurs most often in young children. These

Continued

pathogens along with various types of *Salmonella* and, less frequently, *Shigella* may be causative in nursery epidemics. Cocci are less often at fault. The tetracyclines and sulfonamides as well as drugs which are poorly absorbed from the intestinal tract, such as neomycin, kanamycin, polymyxin B, and colistin sulfate, have been used.

The bacterial causes of food poisoning include the Enterobacteriaceae, staphylococci, streptococci, and organisms of *Clostridia*. In the United States staphylococci are most commonly responsible, but in Europe *Salmonella* is a frequent cause. If the patient remains symptomatic, toxic, and febrile after six to eight hours, the initiation of empiric antibacterial treatment is considered. The use of neomycin, a nonabsorbable sulfonamide, or a tetracycline can be started and, after microbiologic data are known, therapy can be modified accordingly.

The Pancreas

In acute pancreatitis, wherein the patient is moderately or severely ill, antibacterial therapy is often given in an attempt to prevent suppuration, abscess formation, and other infectious complications such as pneumonia and bacteremia. Regimens like streptomycin-tetracycline-nafcillin or kanamycin-chloramphenicol-penicillin provide "coverage."

Clinical and biochemical improvement on long-term use of a tetracycline for two months or longer in some cases of Whipple's disease has been correlated with disappearance of bacilliform bodies from the mucosa of the small intestine as determined by serial biopsy specimens studied by both light and electron microscopy. Similar bacilliform structures undergoing phagocytosis have been described in the macrophages with which the intestinal mucosa and mesenteric lymph nodes are infiltrated. Attempts to culture a specific organism consistently have been disappointing. While there is basic agreement that use of antibacterial agents, such as a tetracycline, may be beneficial in the management of intestinal lipodystrophy, some investigators suggest that the bacterial agents are secondary invaders and that the primary factor involves an unknown, but perhaps cellular, defect in the intestinal mucosa. Workers who have assumed that these bacilliform bodies represent bacteria insist that the requirements for cultural growth have not been met.

Tropical Sprue

In cases of tropical sprue, hematologic and gastrointestinal remission may occur after a tetracycline is used. Perhaps intestinal floral changes with increased bacterial production of folic acid, or tetracycline-induced improvement of jejunal absorptive capacity with greater amounts of dietary folic acid being extracted, are responsible. It has been postulated that underlying intestinal stasis allows orad progression of the colonic flora and that antibiotic therapy corrects this secondary abnormality, while other investigators suggest that the inflammatory and atrophic changes in the enteric villi result from bacterial action and that a tetracycline permits the mucosa to recover and regain its ability to absorb dietary folic acid.

Since some patients having diabetic diarrhea and some having malabsorption associated with other causes, such as intestinal scleroderma may also be improved by use of a tetracycline, it is possible that in these situations, and in Whipple's disease and tropical sprue as well, control of bacterial proliferation in the small intestine is a nonspecific and common explanation for the efficacy of antibiotic therapy under these varying circumstances. Perhaps a primary defect so alters local resistance in these conditions that micro-organisms, including those of exogenous origin and those of the colonic flora, can overgrow in the small bowel, and improvement on antibiotic therapy then reflects elimination of these bacterial invaders. In this regard, it is appreciated that recent data would indicate that less than 1/3 of cultures of material aspirated from the small intestines of human subjects are sterile, and that organisms, usually streptococci and coliform bacilli, are isolated from the majority. If the above hypothesis is correct, it would concern increased numbers of organisms, and perhaps those not normally present.

The Spleen

Splenic abscesses may result from embolization in patients having bacterial endocarditis. Chronic abscesses, associated with evidence of calcification on roentgenograms, may be caused by tuberculosis, histoplasmosis, or brucellosis. In splenic brucellosis,[6] the regimen of streptomycin and a tetracycline may be ineffective without conjoint splenectomy.

Subphrenic or subhepatic abscesses may complicate such situations as appendiceal rupture, duodenal perforation, and postoperative biliary infections.[7] Subphrenic abscesses may be manifested by such thoracic findings as pleuritis, effusion, or pneumonitis; in other cases, such abdominal manifestations as pain, tenderness, and a mass may occur. *E. coli* is usually causative, but other Enterobacteriaceae and cocci may be present. Surgical drainage plus regimens such as streptomycin-tetracycline-nafcillin or kanamycin-chloramphenicol-penicillin are indicated. When microbiologic data are known after operation, antibacterial therapy is modified accordingly.

Perianal abscesses and anorectal fistulae usually require operation, and attempts at definitive therapy with antibacterial agents are unwise. Of course, when such lesions are associated with primary disease such as chronic ulcerative colitis or regional enteritis, then therapy of the underlying condition should precede consideration of surgery. Rarely, bacteremia due to gram negative bacilli occurs after operation. One should recall that a deep ischioanal or ischiorectal abscess is a cause of obscure fever.

Some Infections of the Urinary Tract

Infections of the urinary tract are of varied pathogenesis, symptomatology, and prognosis; consequently their antibacterial management is difficult to generalize. However, there are four commonly used regimens.[8]

Empiric Therapy

Preliminary empiric therapy, often in the form of sulfonamides, is given patients having acute infection without overt evidences of underlying uropathy or predisposing disease. In such cases a Gram-stained specimen of uncentrifuged urine may substantiate the presence of bacteruria. When therapy is given on this basis, the patient may be recovering when cultures are reported. In other patients, such as those allergic to sulfonamides, nitrofurantoin or nalidixic acid may be preferred. In certain infections, especially enterococcal ones, methenamine mandelate has application.

Prophylactic Therapy

Intermittent prophylactic therapy, usually with nonantibiotic antibacterial agents, is given five to 10 days or each month for six to 12 months to patients having acute recurrent infection after unrevealing investigation for underlying uropathy or predisposing disease.

Definitive Therapy

Definitive therapy is given for infections persisting after recent surgical correction of underlying uropathy wherein renal function is threatened, also for abscesses, conjoint bacteremia and the like. Antibiotics are generally used in these situations in accordance with microbiologic and urologic findings. Streptomycin and a tetracycline may be given until microbiologic data are known. When such data are known, ampicillin, cephalothin, kanamycin, polymyxin B, colistin, or chloramphenicol is considered against *E. coli.* Among the objections to use of chloramphenicol is the finding that the drug may be largely excreted in the urine in a conjugated and therefore perhaps inactive form. Excepting ampicillin, the same agents have use against *Klebsiella-Aerobacter* organisms. Kanamycin, chloramphenicol or cephalothin may be useful against *Proteus,* bacilli, whereas penicillin, ampicillin, and novobiocin are of use against *P. mirabilis.* Polymyxin B or colistin are the drugs of choice against *Pseudomonas.* A tetracycline is the drug of choice against *Bacteroides.*

Suppressive Therapy

Suppressive therapy is given patients who have chronic infection not susceptible to eradication in attempts to minimize renal damage and symptoms. Drugs may be given con-

Continued

tinuously, intermittently or alternately; alternate use of agents may minimize floral changes and bacterial resistance. The non-antibiotic antibacterial agents have use in some of these cases.

Patients with acute infections of the urinary tract are treated for at least one week after their clinical and cultural control; persistent infections warrant even longer treatment thereafter. Periodic re-examination ensures that the patient remains free of infection.

Some Infections of the Reproductive System

Fusospirochetal vulvovaginitis and balanitis occur in patients with lowered resistance in whom stomatitis due to these organisms eventuates in systemic invasion. Penicillin is preferred, but the tetracyclines are also effective.

Vaginitis due to *H. vaginalis* is somewhat obscure, but the "clue cells" are said to indicate its presence. Gram-stained smears and wet mounts may aid in detecting the bacilli, but their presence should be confirmed by cultures. A sulfonamide, a tetracycline, or ampicillin may be tried along with local therapy.

While puerperal fever classically represents streptococcal infection, occasionally staphylococci or gram-negative bacilli including *Bacteroides*, are causative. A regimen like penicillin-chloramphenicol-kanamycin may have empiric use in such cases. Cephalothin is being investigated.

Postabortal endometritis is usually due to gram-negative bacilli, but streptococci, staphylococci, or organisms of *Clostridia* may be responsible. Cervical smears may be helpful while awaiting cultural reports. A regimen such as penicillin-chloramphenicol-kanamycin is given, and 12 to 24 hours thereafter the uterus is emptied unless hemorrhage requires immediate operation. Cephalothin is being investigated.

Respiratory Disease Contest

The Minnesota Thoracic Society in association with the Minnesota Tuberculosis and Health Association announces a prize contest for senior medical students, interns and resident physicians in Minnesota.

A. A prize of $200.00 is offered for the best paper submitted by a senior medical student or intern on some aspect of respiratory disease, preferably based upon laboratory or clinical investigation.

B. A prize of $300.00 is offered for the best paper submitted by a resident physician based upon clinical or laboratory investigation in the area of respiratory disease.

The sponsors reserve the right to make no award in either or both categories, based upon the opinion of the judges. Further information may be secured from the Secretary. Entries should be submitted by June 15, 1967, to: David E. Dines, M.D., Secretary, Mayo Clinic, Rochester, Minn.

Medical Ethics

Medicine — a Profession or a Business?

*Address by James Z. Appel, M.D.**
First National Congress on Medical Ethics
Chicago, Illinois
March 5, 1966

The AMA Judicial Council — in connection with this first National Congress on Medical Ethics — plans to publish and distribute a series of essays on significant topics involving medical ethics. The first article in that series, dealing with the question of what the profession should do about the incompetent physician, appeared in the December 20, 1965 issue of the Journal of the American Medical Association.

Medical Incompetence

Medical incompetence is the inability to practice good medicine by modern methods, either because of mental or physical condition, or failure to keep up professionally.

Although incompetent physicians constitute a small minority of the profession, their potential dangers are disproportionate to their numbers. Over the past five years a large proportion of disciplinary actions by state medical boards has been based on various forms of incompetency.

Eight out of 47 state medical societies responding to a survey have provisions in their constitutions or bylaws for disciplinary action against a member for incompetence. Moreover, the laws of only 18 states make specific provision for disciplinary legal action because of physical or professional incompetence. The accredited hospitals, however, do have the authority to deal with incompetent physicians, and the staffs of these hospitals are more and more accepting their responsibilities.

Recommendations

1. The local hospital staff is the logical body to control the incompetent physician.

2. If the incompetent physician proves recalcitrant, the hospital staff should next turn to the grievance committee of the local or county society.

3. Only if efforts at the local level fail should the state society be asked to deal with the case.

4. Where there is convincing evidence that the incompetent physician has violated the law, the hospital staff should refer the case directly to the board of medical examiners.

---

*Past President American Medical Association.

Continued

5. The hospital licensing body, by regulation and, if necessary, by legislation, should make every effort to apply the criteria of the Joint Commission to the fringe hospitals which are unaccredited.

6. Every medical practice act should specify incompetence as grounds for disciplinary action.

7. Although most problems are best handled at the local level if possible, there should be the closest cooperation among the hospital staff, the county and state medical societies and the boards of medical examiners.

This matter can not be left entirely up to the hospital staffs. The county societies must be more vigilant and active in dealing with the problem of incompetence.

The Authority of the State Board

It is understandable that one's immediate confreres might be hesitant to initiate any drastic action against a fellow physician who in the past has had an enviable record but who because of age or other form of adversity falls behind the mainstream of competency. The jurisdictional mechanism available to the state or national organization will stimulate activity at the local level.

The authority and activity of the state boards must be increased. Up to this time the principal function of state examining boards has been in the area of licensing. Two days of examination is a very inadequate method of determining a man's qualifications for medical and surgical practice, not only at the time of examination but also for the rest of his life; however, it is the only method we have.

It is doubly necessary to strengthen our medical practice acts because some incompetent physicians are members neither of a hospital staff nor of a medical society. These are the most dangerous kind, and they can be controlled only by the state boards.

Medical Ethics

As we move ahead in our expanded program of medical ethics, the essential, vital ingredient is the spirit of professionalism.

Most of us know, but rather tend to take for granted, the fact that a profession is primarily a calling for public service. For the conscientious doctor this involves a great deal of self-denial. The well-being of the patient comes ahead of the personal interest of the physician.

Another characteristic of our profession is that it is willing to accept and to exercise its responsibility of self-discipline and self-elevation of standards of quality. This First National Congress on Medical Ethics is evidence of the organizational acceptance of such responsibility. Our goal is to obtain maximum, *individual* recognition and acceptance of that responsibility.

If medicine remains true to its professional ideals, the public will have confidence in us and will not seek to protect its "interests" through politicians, by legislation or in other ways. Conversely, to the extent that we drift away from the principle of public service, the public might develop feelings of unrest and dissatisfaction which could lead to the conversion of medicine into a new kind of "public utility." Today there are more professions and professional people than ever before, and the trend toward more professionalism will probably continue to accelerate as society becomes more complex.

Professionalism

We must bear in mind that the world is debating the question of how society should be organized. Should it be organized for the individual, with maximum freedom, opportunity and responsibility for every person, or should it be organized for the group or state — with the individual subordinate to a government which dominates and controls most social, economic and political decisions?

The spirit of professionalism, like the sense of individuality, will have a strong influence on the ultimate answer. For us in medicine, as we face the many problems and challenges that confront us, one of our major responsibilities is to stimulate and nurture a genuine sense of professionalism — professionalism as a way of life.

In this connection the Journal of the American Medical Association pointed out recently that the famed scientist, Vice Admiral H. G. Rickover, reminded us last year that ours is a truly liberal and humanistic profession.

"Of all technologies," Admiral Rickover said in his Granada Lecture before the British Association for the Advancement of Science, "that of the physician has benefited man most and harmed him least. The stringent standards set by the profession and by society for the education and professional conduct of physicians account for this happy circumstance.

"Not only is no one permitted to practice who has not given proof of his competence, but physicians must also be broadly, liberally, humanistically educated men and women. This gives them perspective in evaluating their professional actions, an ability to see these actions against a humanistic background."

As the Journal said, the real significance of the Admiral's remarks lies in the fact that they were not intended as tributes to the medical profession, but rather as ideals for engineers — in the hope that they too would find it possible "to act with the same sense of professional responsibility and service to humanity which is characteristic of good physicians."

This independence of professional judgment cannot be taken for granted. "It lies," as Admiral Rickover reminds us, "in the determination of the medical profession to resist lay interference and its success in winning this point."

Service to Humanity

We will resist further interference and win our point only by emphasizing and maximizing the professional aspects of medicine and by deemphasizing and minimizing the business and financial aspects.

As individuals and as a group, we must constantly bear in mind the basic principle that "the primary object of the medical profession is to render service to humanity; reward or financial gain is a subordinate consideration." This points up the sharpest, greatest difference between medicine and business.

Most people do not expect a businessman to be motivated primarily by any other desire than that of making money. If it so happens that the principles of service and altruism help him toward that goal, so much the better. However, if sharp practices and deception, within legal limits,

Continued

enable him to achieve his objective more profitably, the public usually accepts these facts — possibly with resentment but not with great surprise or deep feelings of betrayal.

As Dr. Leonard W. Larson, past president of the AMA, pointed out in his inaugural address in 1961, the professional spirit is an unchangeable force in medicine. While its outward forms and applications may change with the course of history and alterations in the human environment, its essence is unchangeable, indestructible.

When the essence of that spirit is diluted or destroyed, either in an individual physician or in a nation, medicine ceases to be a profession in the highest sense of the word. Without the true professional spirit, the practice of medicine becomes simply an occupation, a way of earning a living.

The really good doctor, guided by the professional spirit, will always remember that medicine exists for just one purpose — to serve humanity — and he will strive for excellence in meeting that purpose. No matter how or to what degree the scientific and socio-economic patterns of medical practice may change in the future, we have the responsibility of preserving and invigorating the essence of the professional spirit.

Syphilis and History

History has been profoundly influenced in some cases by the effects of syphilis upon rulers. Ivan the Terrible of Russia suffered from cerebral syphilis, which drove him to deeds of horrible cruelty. The reign of several of the Tudors in England was marked by the almost unmistakable effects of syphilis. Henry VIII had a series of still-born children, strongly suggestive of the syphilis with which he was said to be infected. His son, Edward VI, died at an early age of what appeared to be a combination of congenital syphilis and tuberculosis. His daughter Mary — Bloody Mary — shows in her pictures the facial expression quite typical of the congenital disease. Henry himself had an abscess in his thigh, probably syphilis of the bone, which troubled him for many years. His marked sensuality developing in middle life and his blood-thirsty habits of divorce are strongly suggestive of cerebral syphilis. What a difference in the Tudor reign modern methods of treating syphilis might have made! Even Henry the VIII, after enduring the heroic treatment for syphilis current a hundred years ago, might have been thus converted into a misogynist as Arthur Schopenhauer was said to have been.*

The astrologers, having observed that syphilis invaded those parts of the body which they believe to be under the influence of Venus, called the disease *lues venerea,* or venereal infection.**

Abstracts, Briefs and Commentaries

GASTRIC HYPOTHERMIA FOR HEMORRHAGE

Though gastric hypothermia for the cure and treatment of ulcer has not been extensively accepted, a simple method of gastric hypothermia for the control of massive hemorrhage of the stomach has been demonstrated by Hubbard to be of definite value in fifteen patients who would otherwise have been subjected to emergency operation for the control of the bleeding.

A size 18 French plastic nasal tube was passed through each nostril to the stomach. One tube was connected to a suction of low power; the other was connected by a rubber tubing to an open-end flask suspended from an intravenous stand. A Murphy drip was inserted so that the rate of flow could be evaluated, and an electrolyte solution containing .745 grams of potassium chloride and 2.0 grams of ammonium chloride per liter was used as the irrigating solution. This was buffered to a ph of 7.4 with sodium bicarbonate, as originally suggested by Wangensteen. Chipped ice was added to the solution, and 3,000 to 4,000 cc. of irrigating fluid was run through the stomach over each four-hour period. The solution was removed from the stomach at the same rate, either by low suction or by gravity.

Control of the gastric bleeding was provided in all 15 cases within a period of 24 hours. In those cases in which the inflow temperature was measured, it was found to be from 1 to 4 degrees centigrade, and the outflow temperature was from 18 to 21 degrees.

Editor's Note: This relatively simple lifesaving measure can be carried out without special equipment and certainly should be worth a trial in any patient who enters the hospital with massive gastric hemorrhage.

Crampton et al., who carried out a somewhat similar study on 60 patients, in which they used a Swanko gastric hypothermia unit and a stomach-shaped balloon, circulating a mixture of equal parts of 90 percent alcohol and water through the coaxial tube, were able to obtain control in 83 percent of their patients. The highest instance of control was obtained within a period of 24 hours; those that required more than 24 hours to control the initial bleeding had rebleeding while in the hospital. Because of this Crampton and his associates advocated that emergency surgery should be performed whenever possible if the patient initially controlled by hypothermia rebleeds during hospitalization.

Continued

Editor's Note: In the 15 cases reported by Hubbard, the cold electrolyte solution came in direct contact with the mucosa of the stomach, whereas in the cases reported by Crampton et al. only the balloon was in direct contact with the stomach mucosa. It may be that mechanical washing associated with cooling, as observed in Hubbard's group, could be a factor in more effectively controlling the gastric hemorrhage. It would seem that Hubbard's method is worth additional trial.

TREATMENT OF HYPERTENSION

A follow-up study of 97 hypertensive patients with group 3 hypertension (or retinopathy) and 64 patients with malignant (group 4) hypertension clearly demonstrated that medical treatment improves the prognosis, although the mortality rate remained disappointingly high. The 5-year survival rate was 37.5% for patients with group 3 retinopathy and 28.6% for patients with malignant hypertension. Inadequate control of blood pressure, cessation of therapy, short duration of hypertension, and significant azotemia were associated with worse-than-average mortality rates. Effective treatment not only prolonged life but led to the regression of retinal hemorrhages, exudates and papilledema, but control of the hypertension did not seem to influence favorably those complications that are due to atherosclerosis, especially cerebrovascular accident. More than 10% of the survivors suffered cerebral vascular accidents, and this complication was the leading cause of death in this series. The marked relationship found between the degree of control of hypertension and longer survival suggests that more effective and better tolerated drugs will further improve the prognosis in severe hypertension.

GASTRIC LYMPHOMA

Two pathologists made a retrospective survey of 71 patients with gastric lymphoma. At the time of diagnosis 65 patients had primary gastric tumors and six were associated with diffuse disease. Most patients had less than six months of symptoms. The five-year and ten-year survival rates for primary lesions were 59 and 28 percent. The best prognosis occurred with small, superficial lesions confined to the stomach. In long-term survivals, lymphoma of the stomach is not necessarily a manifestation of systemic disease.

VASECTOMY

Vasectomy is a common method of contraception which previous investigations have found to be well accepted by most patients. However, because of occasional reports of adverse changes in sexual functioning, psychological adjustment, and family relationships, Drs. Ziegler and Rodgers have investigated the psychological sequelae of vasectomy. In a preliminary study they administered the Minnesota Multiphasic Personality Inventory (MMPI) to a large group of patients both before and after they underwent vasectomy, and postoperative changes in MMPI scores suggested that these patients had become depressed and anxious. In order to confirm this impression, the authors interviewed 42 couples before and after the husband had undergone vasectomy and another 42 couples before and after the wife had received a prescription for an ovulation-suppressing drug. In addition, four months after the initial interview, both groups were asked to complete the California Personality Inventory, the Scripps Clinic Self Description Scale, the MMPI, and the Scripps Clinic Child Rearing Attitude Scale. At the time of the second interview, both groups expressed satisfaction with the contraceptive technique prescribed, the vasectomized husbands even portraying themselves as being more decisive and more inclined to form close, permanent interpersonal ties than before surgery. Indeed, item changes on the self-description inventories suggested that the vasectomized husbands were more masculine than the husbands in the control group and that the wives of the vasectomized husbands had assumed a more complementary and compliant marital role than the wives in the control group. However, as in the preliminary study, changes in postoperative MMPI scores contradicted this impression. Though psychological disorganization of the vasectomized men did not occur, test results indicated unfavorable personal and psychological adjustment.

Thus, the data gathered by Drs. Ziegler and Rodgers suggest first that vasectomized patients uniformly report good results and picture their postoperative psychological health as improved, and second, that postoperative psychological tests do not confirm these assertions but, instead, show that vasectomy is often followed by troubled, anxious, and depressed mental states. It appears that men who undergo vasectomy tend to deny or rationalize fear and concern over this procedure and to claim a more favorable outcome than is really the case.

SONS OF ALCOHOLICS

To obtain indirect evidence regarding the personality of potential alcoholics, sons of alcoholic men were studied by a 36-item behavorial questionnaire constructed to measure personality traits common in alcoholics. Forty-one sons of alcoholics were compared with 123 matched controls by classroom teachers. Contrary to the hypothesis tested, sons of alcoholics were rated less personable and more overtly aggressive than the controls. The results

Continued

were interpreted as showing a passive-aggressive personality preceding and possibly leading to alcoholism.

ANESTHESIA IN ASTHMATICS

In a continuous three-yr. investigation of 220 anesthetics administered to 196 asthmatics who were studied for operative and postoperative morbidity and mortality, the significant findings were these: (1) Complications were more frequent in the asthmatic than in the nonasthmatic surgical population. (2) Approximately 75% of the complications were pulmonary. (3) Such complications were more common in asthmatics who received (a) a high spinal anesthesia for intraperitoneal surgery or (b) the combination of thiopental induction with cyclopropane for maintenance but not necessarily when these agents were used separately. (4) Halothane anesthesia resulted in the fewest complications. (5) There was no correlation between the severity of asthma and the complication rate, but there was a higher incidence of complications with longer surgery and duration of anesthesia, especially for surgery of the abdomen or chest. (6) Male asthmatics encountered significantly more complications than females.

RADIATION EFFECT ON THYROID

A group of adult patients, treated by roentgen rays for diseases of the thyroid, was followed for 10 to 35 years to determine the possible carcinogenic effect of such radiation on the thyroid gland. This group was compared with a series of patients similarly treated during adolescence and with another group treated in childhood. A direct relationship between roentgen therapy to the neck region and the subsequent development of thyroid cancer appears to exist in those treated in childhood and adolescence. The data now available suggest that the younger the patient when treated, the greater the possibility of development of thyroid carcinoma. The data also indicate that the interval between radiation and the development of carcinoma is considerably less in children than in adolescents. Roentgen therapy does not appear to be a carcinogenic factor in adults.

A Face Is Really Many Generations

Every human face is a living composite of countless faces — generations and generations of faces. And any living face, well watched by love or hate, will reveal a hundred different aspects.

The more familiar we become with any common face, the more astonishing the multitude of transformations we observe in it, the more bewildering its fugitive subtleties of expression.

Death itself may bring into the countenance some strange expression never noticed during life.—Lafcadio Hearn

The Doctor's Workshop

Two Technical Aids in Wound Closure

A WEAK, easily torn peritoneum is an exasperating problem in abdominal wound closure during surgery. While the anesthesiologist is decreasing the anesthesia so that the patient will not be obtunded in the approaching post-anesthesia period, the surgeon is struggling to pull together a layer which tears with every stitch (Figure 1). To obviate this problem the following simple measure has been employed.

If there appears to be tension on the peritoneum, an interrupted suture of heavy silk or braided wire is placed in the fascia in the mid-portion of the wound and the suture is tied. This places the tension on the strongest layer of the wound and allows secure, easy closure of the peritoneum.

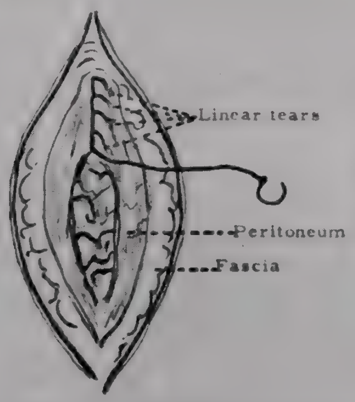

Fig. 1 — Usual Technique of Peritoneal Closure.

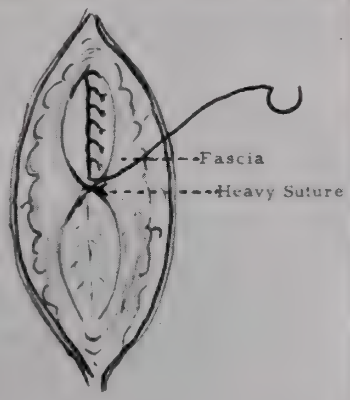

Fig. 2 — Peritoneal Closure with Center Fascial Suture.

Closure of the subcutaneous fat in an obese patient can be an arduous task. A commonly used method (Figure 3) involves multiple layers of interrupted plain catgut sutures placed with a round curved needle so that circular "bites" of tissue are taken. This technique of rotating a curved needle through tissue is essential in many areas and, naturally, becomes an automatic motion with surgeons. However, when this technique is applied to the subcutaneous fat, large areas are compressed, reducing blood supply and predisposing to necrosis and abscess formation. In addition, wounds

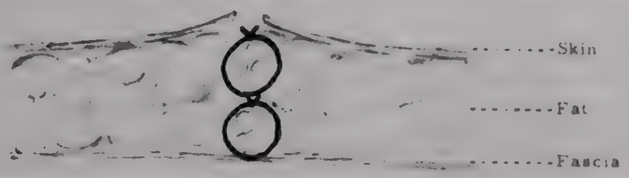

Fig. 3 — Usual Technique of Subcutaneous Closure.

Continued

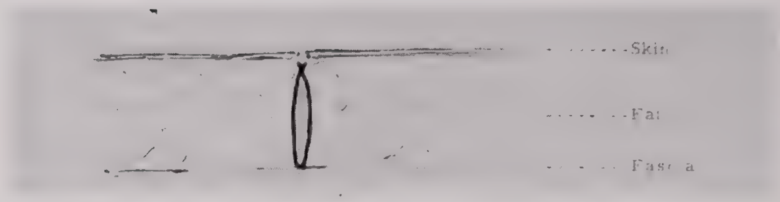

Fig. 4 — Subcutaneous Closure with Vertical Suture.

closed in this manner tend to gape and create a widely spread scar.

To correct these defects and obtain an anatomical closure, the suture, on a large curved needle, is passed from the skin along the edge of the fat to the base of the wound and brought up on the other side in a similar manner. One row of these sutures placed one to two centimeters apart closes a layer of fat of any thickness, with no gaping and a minimal amount of fat compression.

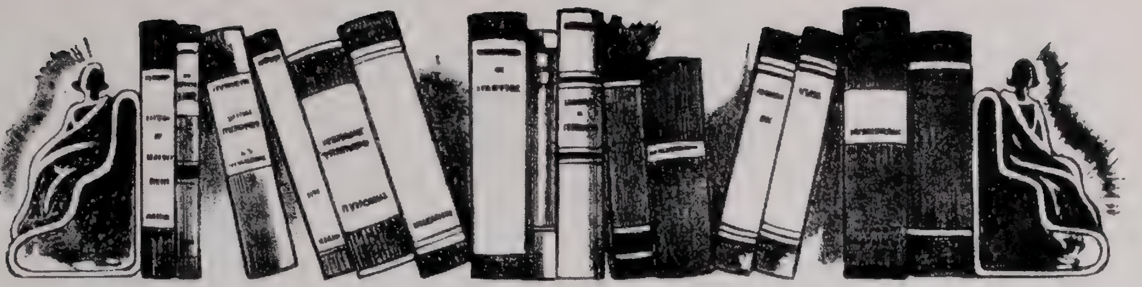
Ills

So of doctors. They like fees no doubt — ought to like them; yet if they are brave and well-educated, the entire object of their lives is not fees. They, on the whole, desire to cure the sick; and — if they are good doctors, and the choice were fairly put to them — would rather cure their patient, and lose their fee, than kill him, and get it. — John Ruskin (1819-1900)



Book Reviews

Good books like good friends are few and chosen, the more select the more enjoyable. — Alcott

PEDIATRIC THERAPY, 2nd Edition — Harry S. Shirkey, M.D. (Editor) C. V. Mosby Company. $18.50.

This is an outstanding contribution to the care of infants and children, and Dr. Shirkey is to be complimented on the comprehensiveness and adequacy of the material covered. Admittedly, therapy is a treacherous domain; but for the most part the presentations are representative of current practices with enough explanatory text to make the discussions meaningful.

To attempt to critically review this prodigious text of 1223 pages would not be either practical or pertinent. It is not too difficult to find an occasional approach which doesn't meet with approval; but more remarkable is the fact that so much has been covered so well. It would seem best to leave it to the individual reader to find his points of disagreement.

A preface which contains the statement "complete treatment of the child is encouraged, and consideration is given to all those who contribute to his more complete care" shows immediate promise of a most ambitious undertaking. It is a tribute to the editor that he has organized the material so that this objective is sustained throughout the book.

The thoroughness of the coverage is such that the practicing physician will find this to be of great assistance in defining a therapeutic approach to a particular problem. For the most part the various editors have been most direct in their treatment providing an immediate practical approach for the interested physician. The intern and resident should find this compendium of pediatric therapy an essential companion as they enlarge their experiences in pediatric care.

The book is well-organized, illustrations are profusely used and the writing is, with few exceptions, concise and readable. My main concern is the ambitiousness of the undertaking with the inevitable necessity to compromise some of the subject matter. However, in contrast with other texts of similar content, Dr. Shirkey's book combines both adequacy and comprehensiveness in one volume and is highly recommended to all physicians who have a responsibility for the care of children.

THERAPEUTIC RADIOLOGY — RATIONALE, TECHNIQUE, RESULTS — by William F. Moss, M.D., The C. V. Mosby Company, St. Louis, Mo., Second edition, 514 pages $15.00.

This is a completely revised edition of a well written concise textbook. The first edition was well appreciated by its users. This edition is brought up to present day knowledge and concept of the megavoltage therapy. It describes in necessary detail different cancers and their therapeutic management with particular application to radiotherapy.

A new chapter is added dealing with combination of radiotherapy and surgery. There is increasing interest among radiotherapists and surgeons about preoperative radiation with the hope of improving control of the primary cancer.

This book is recommended to radiology residents and radiotherapists as a guideline for cancer management. It is concise but contains all the pertinent facts for a good cancer radiotherapy. Other physicians may use it to familiarize themselves with the radiotherapeutic management of the cancer and acquire more knowledge of the effects of ionizing radiation on malignant growth as well as healthy tissues.

Arnolds Veinbergs, M.D.

PERIPHERAL VASCULAR DISEASES — Travis Winsor and Chester Hyman, Lea & Febiger, Philadelphia, Copyright 1965.

This monograph has twenty-five small chapters dealing with the various phases of peripheral vascular diseases and includes some studies pertaining to peripheral fluids and lymph formation. It discusses arthritis, collagen disease, arterial aneurysms and fistulas, and the neurovascular syndrome of the upper extremities.

It is well bound and nicely printed. The index is not extensive but is adequate. The book is worth a place in the library of one who is interested in peripheral vascular diseases.

Carl O. Rice, M.D.
Minneapolis, Minnesota

Norinyl® tablets
(norethindrone 2 mg. c̄ mestranol 0.1 mg.)

for multiple contraceptive action that has produced a record of unexcelled effectiveness

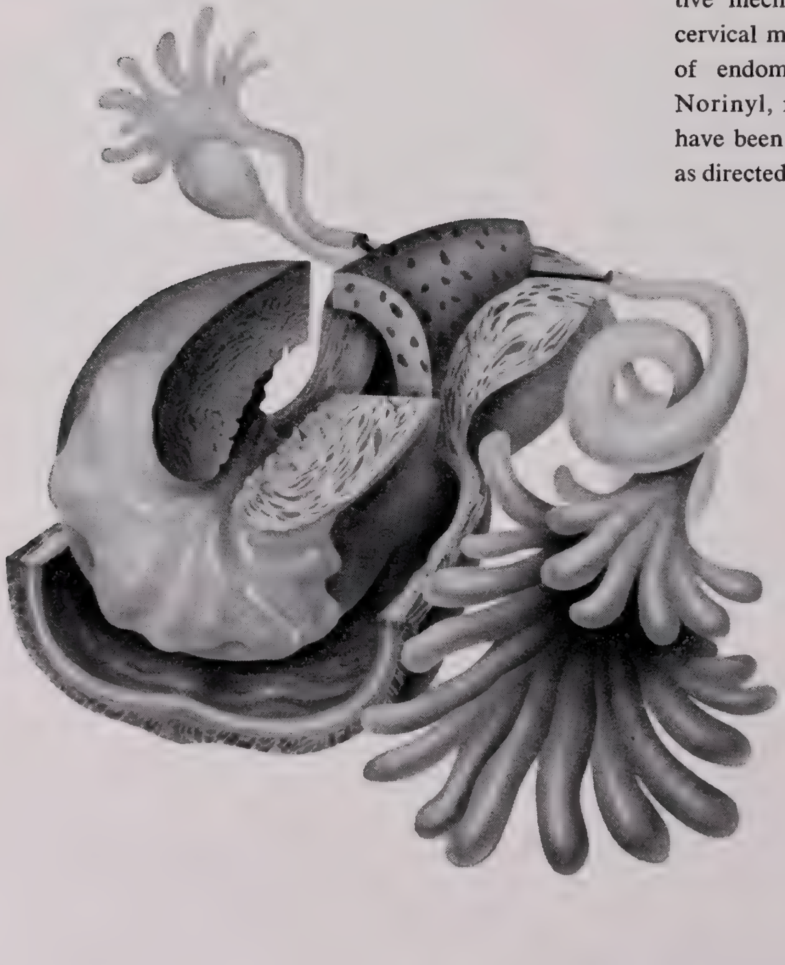
inhibition of ovulation by means of 2 time-proved hormonal agents

production of a cervical mucus hostile to sperm motility and vitality

creation of an endometrium unreceptive to egg implantation

no unplanned pregnancies

Norinyl provides multiple action for maximum assurance of success. It does not depend on ovulation inhibition alone for contraceptive effectiveness. The mechanism of action of combined hormonal therapy results in ovulation inhibition reinforced by other protective mechanisms, including a hostile cervical mucus[1-13] and an acceleration of endometrial changes.[1-3,7-16] With Norinyl, no unplanned pregnancies have been reported to date when used as directed.



plus important supportive benefits that help her through those critical early months of oral contraception

low incidence of side effects

Low incidence of BTB and spotting, nausea and amenorrhea tends to minimize side effect problems and increases patient cooperation.

no confusion about dosage

An unbreakable "confusionproof" package makes it easy to adhere to prescribed dosage schedule: individually sealed tablets numbered from 1 through 20 *plus* monthly calendar record enables patient to double-check dosage intake by day and corresponding tablet number.

NORINYL
2
SYNTEX
T F S
2
1

Contraindications: Thrombophlebitis or pulmonary embolism (current or past). Existing evidence does not support a causal relationship between use of Norinyl and development of thromboembolism. While a study which was conducted does not resolve definitively the possible etiologic relationship between progestational agents and intravascular clotting, it tends to confirm the findings of the Ad Hoc Advisory Committee appointed by the Food and Drug Administration to review this possibility. Cardiac, renal or hepatic dysfunction. Carcinoma of the breast or genital tract. Patients with a history of psychic depression should be carefully studied and the drug discontinued if depression recurs to marked degree. Patients with a history of cerebral vascular accident.

Warning: Discontinue medication pending examination if there is sudden partial or complete loss of vision, or if there is a sudden onset of proptosis, diplopia or migraine. If examination reveals papilledema or retinal vascular lesions, medication should be withdrawn.

Precautions: By May 1963, experience with norethindrone 2 mg.—mestranol 0.1 mg. had extended over 24 months. Through miscalculation, omission or error in taking the recommended dosage of Norinyl, pregnancy may result. If regular menses fail to appear and treatment schedule has not been adhered to, or if patient misses two menstrual periods, possibility of pregnancy should be resolved before resuming Norinyl. If pregnancy is established, Norinyl should be discontinued during period of gestation since virilization of the female fetus has been reported with oral use of progestational agents or estrogen. When lactation is desired, withhold Norinyl until nursing needs are established. Existing uterine fibroids may increase in size. In metabolic or endocrine disorders, careful clinical preevaluation is indicated. A few patients without evidence of hyperthyroidism had elevated serum protein-bound iodine levels, which in the light of present knowledge, does not necessarily imply hyperthyroidism. Protein-bound iodine increased following estrogen administration. Bromsulphalein retention has occurred in up to 25% of patients without evidence of hepatic dysfunction. Studies from 24-hour urine collections have shown an increase in aldosterone and 17-ketosteroids and decrease in 17-hydroxycorticoid levels. Thus, Norinyl should be discontinued prior to and during thyroid, liver or adrenal function tests. Because progestational agents may cause fluid retention, conditions such as epilepsy, migraine and asthma require careful observation. Thus far no deleterious effect on pituitary, ovarian or adrenal function has been noted; however, long-range possible effect on these and other organs must await more prolonged observation. Norinyl should be used with caution in patients with bone, renal or any disease involving calcium or phosphorus metabolism.

Side Effects: Intermenstrual bleeding; amenorrhea; symptoms resembling early pregnancy, such as nausea, breast engorgement or enlargement, chloasma and minor degree of fluid retention (if these should occur and patient has not strictly adhered to medication plan, she should be tested for pregnancy); weight gain; subjective complaints such as headache, dizziness, nervousness, irritability; in a few patients libido was increased. In a total of 3,090 patients, 2.2% discontinued medication because of nausea.

NOTE: See sections on contraindications and precautions for possible side effects on other organ systems.

Dosage and Administration: One Norinyl tablet orally for 20 days, commencing on day 5 through and including day 24 of the menstrual cycle. (Day 1 is the first day of menstrual bleeding.)

Availability: Dispensers of 20 and 60 tablets; bottles of 100.

A Comparative Study on Selected Variables of Atopic and Non-Atopic Institutionalized Juvenile Delinquent Boys

ELMER M. RUSTEN, M.D.
E. MICHAEL RUSTEN, M.A.
Minneapolis, Minnesota

THE PURPOSE OF this study was to compare atopic* and non-atopic institutionalized juvenile delinquent boys on selected variables. There have been a number of studies made on the personality characteristics of atopic individuals. Characteristics reported include above average intelligence,[1,2,3] hostility,[4,5,6] resentment[3,6,7] aggression which is often suppressed,[1,8] and disrespect for the law.[6] Some studies[8,9,10] reported major sexual problems, whereas others[6,11] reported either only minor sexual disturbances or none. Allergics tended to be dissatisfied with their family life, to alienate their friends, to be cynical, irritable and grouchy, with no compensation techniques for their feelings of inferiority.[6]

This study first sought to determine whether there was a higher incidence of atopy among juvenile delinquent boys than in the general populace. Secondly, it also sought to investigate the relationship of atopy to race, intelligence, and type of committing offense among atopic and non-atopic institutionalized delinquents.

Procedure

The 322 boys who were inmates of the State Training School for Boys, Red Wing, Minnesota, as of midnight June 30, 1964, were the subject of the study. They ranged in age from thirteen to eighteen. The hospital records were consulted to determine which inmates had a history of atopic disease. The race, intelligence quotient, and type of offense were determined from other institutional records.

Results

Table 1 shows the incidence of atopy among the subjects. Ninety-nine or 30.7 per cent showed a history of some atopic disease.

Table 2 shows the breakdown of the atopic diseases found among the subjects. Seasonal

Continued

pollenosis had the highest frequency of 14.0 per cent; atopic dermatitis occurred in 5.9 per cent, while bronchial asthma and vasomotor rhinitis both had frequencies of 4.7 per cent.

Previous studies have sought to investigate the incidence of allergic diseases among the general population. Those reported since 1930 are found in Table 3. In 1930 Piness and Miller[12] reported the incidence of seasonal pollenosis in the population of two Arizona towns. In a town of 3000 population 4.4 per cent had histories of seasonal pollenosis, while in a town of 1000 the percentage was 3.0. In 1931 Rowe[13] made a study of 400 unselected students and nurses. Of these 35 per cent had a history of probable allergy. In 1934 Vaughan,[14] in a survey of an entire community of 508 individuals at Clover, Virginia, classified allergies as major and minor. Minor allergies were defined as minor episodic allergic manifestations due to contact with an allergen. The symptoms of minor allergies are transient and are relieved by avoiding the exciting allergens such as house dust, cosmetics, and offending fumes. Asthma and seasonal pollenosis were not included in this category. Vaughan found 10.8 per cent of the population to have major allergies and 48.1 per cent to have minor ones. Jimenez[15] investigated 7000 entering students at Michigan State University and found 35.0 per cent to be allergic. In 1937 Pipes[16] included 700 persons in a survey in and about Baton Rouge, Louisiana. Included in this study were secondary school children and students at Louisiana State University. Of these, 13.6 per cent were found to have major allergies and 35.8 per cent minor allergies. Service[17] in 1939 investigated 3141 persons in Colorado Springs, Colorado. Of these 22.6 per cent had a history of major allergy. Bernton[18] in 1957 made a survey of allergic disease among a prison population of 1500 in Washington, D.C. Of these 11.3 per cent had a major allergy while 11.7 per cent had a minor allergy. In a study in 1958 of 1225 children in a pediatric group practice in Tennessee, Crook, Harrison, and Stanley[19] found 14 per cent to be allergic and an additional 18 per cent to be probably allergic. Appel, Szanton, and Rapaport[20] in a survey of 6036 children found that over 23 per cent had one or more major allergies. In comparison with these studies the current investigation found 30.7 per cent of the subjects to be atopic.

TABLE 1
Incidence of Atopy Among Institutionalized Juvenile Delinquent Boys

Group	No.	%
Atopic	99	30.7
Non-atopic	223	69.3
Total	322	100.0

TABLE 2
Incidence of Atopic Diseases Among Institutionalized Juvenile Delinquent Boys

Atopic Disease	No.*	%
Seasonal pollenosis	45	14.0

Bronchial asthma	15	4.7
Vasomotor rhinitis	15	4.7
Urticaria	13	4.0
Sick headaches	9	2.8

*Some boys had more than one atopic disease.

The incidence of atopy according to race is found in Table 4. Approximately 30.5 per cent of the whites were found to be atopic, compared to 47.6 per cent of the Negroes and 21.4 per cent of the American Indians. However, the number of Negroes and American Indians included in the study was too small to draw any firm conclusions from the data.

The intelligence estimates of the two groups are compared in Table 5. The atopic subjects had slightly higher intelligence estimates than the non-atopic. Three-fourths of the atopic group had intelligence estimates of average or higher, while this was true of only slightly over two thirds of the non-atopic group. This substantiates the findings of the previously listed studies.

The types of crimes for which the atopic and non-atopic subjects were committed to the institution are recorded in Table 6. An identical percentage of 64.6 per cent of atopic and non-atopic subjects had committed crimes against property. However, twice as high a percentage of atopic subjects had committed crimes against persons as compared to non-atopic subjects. Approxi-

mately 16.2 per cent of the atopic group had committed this type of crime as opposed to only 8.1 per cent of the non-atopic group. A higher percentage of atopics than non-atopics had also committed crimes against justice. The percentage for the the atopic group was 41.4 per cent as compared to only 32.9 per cent for the non-atopic group. On the other hand, all five of the subjects committing crimes against morals, chastity and decency were non-atopics.

Table 7 shows a breakdown of the actual crimes committed by the subjects. The greatest differences between atopics and non-atopics were found in the crimes of robbery and burglary. Of the atopic individuals 9.1 per cent had committed robbery as opposed to only 3.1 per cent of the non-atopics. On the other hand, 16.1 per cent of the non-atopics had committed burglary as compared to only 8.1 per cent of the atopics. The atopics thus tended to commit crimes against persons.

Summary and Conclusions

The study sought to investigate the incidence of atopy among institutionalized juvenile delinquent boys and to determine the relationship of atopic disease to race, intelligence, and type of committing offense. The 322 boys who were inmates of the State Training School for Boys, Red Wing, Minnesota, as of June 30, 1964, served as subjects for the study. The results were as follows:

1. The incidence of atopy among the institutionalized juvenile delinquents studied was 30.7 per cent. This was medial of the percentages in the general population as reported by eight authors.
2. There was a higher incidence of atopy among Negroes than whites.
3. The intelligence estimates of the atopics were slightly higher than those of non-atopics.
4. A higher percentage of atopics than non-atopics were committed to the institution for crimes against persons and justice. No atopics were committed for crimes against morals, chastity, or decency.

Acknowledgment

It is the authors' privilege to record their appreciation and thanks to Nathan Mandel, Ph.D., Director of Research, Minnesota Department of Corrections; to Mr. Delbert Leaf, Superintendent, State Training School for Boys, Minnesota Department of Corrections; and to the several members of their staffs for the cooperation and help which has made this study possible.

---

*A New View of Corticosteriod Action in Inflammatory Dermatoses
A 16 mm. film utilizing time-phase cinemicrographic techniques. Available for showing on request to Syntex Laboratories.

In contact dermatitis

Synalar®

(fluocinolone acetonide)

stabilizes cell and capillary walls
protects against the chemical impact of cytotoxins

---

interrupts the chain reaction of destructive
changes at the cellular level

---

permits inactivation, absorption and transportation
of toxins away from the injured area by natural
processes...edema is absorbed and cells return
to normal size, shape, and activity

In inflammatory dermatoses choose a steroid synthesized specifically for topical use. Synalar (fluocinolone acetonide) provides therapeutic results often comparable to those of systemic and intralesional corticosteroids with fewer hazards.[1-3]

---

when complicated by infection

neo-synalar®

(fluocinolone acetonide-neomycin sulfate cream)

For initiation of therapy: Cream 0.025%, 5 and 15 Gm. tubes, 425 Gm. jars; **for emollient effect:** Ointment 0.025%, 15 Gm. tubes; **for maintenance therapy:** Cream 0.01%, 15 Gm. tubes, 45 Gm. tubes, 120 Gm. jars; **for intertriginous or hairy sites:** Solution 0.01%, 20 cc. and 60 cc. plastic squeeze bottles; **for infected inflammatory dermatoses:** Neo-Synalar® Cream (0.025% fluocinolone acetonide, neomycin sulfate, equivalent to 0.35% neomycin base), 5 and 15 Gm. tubes.

Contraindications: Tuberculous, fungal, and most viral lesions of the skin, (including herpes simplex, vaccinia, and varicella). Not for ophthalmic use. Contraindicated in individuals with a history of hypersensitivity to any of its components. **Precautions:** Synalar preparations are virtually nonsensitizing and nonirritating. However, the solution may produce burning or stinging when applied to denuded or fissured areas. In some patients with dry lesions, the solution may increase dryness, scaling or itching. The neomycin in Neo-Synalar Cream rarely produces allergic reactions. Prolonged use of any antibiotic may result in overgrowth of nonsusceptible organisms; if this occurs, appropriate therapy should be instituted. Where severe local infection or systemic infection exists, the use of systemic antibiotics should be considered, based on susceptibility testing. While topical steroids have not been reported to have an adverse effect on pregnancy, the safety of their use on pregnant females has not absolutely been established. Therefore, they should not be used extensively on pregnant patients, in large amounts, or for prolonged periods of time. **Side Effects:** Side effects are not ordinarily encountered with topically applied corticosteroids. As with all drugs, however, a few patients may react unfavorably to Synalar under certain conditions.

GEORGE B. EUSTERMAN, M.D.

Dr. George B. Eusterman, Sr., 84, a member of the staff of the Mayo Clinic, died July 11, in Rochester. He was born in Lewiston and received his degree of doctor of medicine at the University of Minnesota.

He was certified as a specialist in internal medicine by the American Board of Internal Medicine in 1940 and became a member of the examining board in the subspecialty of gastroenterology. He was an emeritus member of the American Medical Association, a fellow of the American College of Physicians, member of the Central Society for Clinical Research, the Central Interuban Clinical Club, the Minnesota Society of Internal Medicine and a corresponding member of a number of foreign scientific organizations.

In 1921 Dr. Eusterman was president of the American Gastroenterological Association, and in 1946 this organization awarded him the Friedenwald Medal for outstanding work in gastroenterology. He was the author of approximately 150 papers dealing with diseases of the upper part of the digestive tract and metabolism and nutrition. He was awarded a certificate of merit by the University of Minnesota, a certificate of Master of the American College of Physicians and was a 50 Club and associate member of the Minnesota State Medical Association in addition to being a member of the Zumbro Valley Medical Society.

He is survived by his wife, three daughters and two sons, Dr. George Eusterman, Jr. of Great Falls, Montana, and Dr. Joseph H. Eusterman of Albany, Oregon.

GEORGE M. TANGEN, M.D.

Dr. George M. Tangen, 68, Taylors Falls physician, died July 25, of a heart attack while working in his yard. Born in Duluth, he received his medical degree at the University of Minnesota Medical School. Dr. Tangen practiced in Canby for fifteen years before moving to Minneapolis in 1940.

He was a member of the medical staffs of Abbott and St. Barnabas Hospitals, and an associate professor in the Department of Otolaryngology at the University of Minnesota Hospitals. Dr. Tangen was a member of the American Medical Association and Hennepin County Medical Society and an associate member of the Minnesota State Medical Association.

He is survived by his wife, a daughter and a son, Dr. George V. Tangen of Minneapolis.

WILLIS H. THOMPSON, M.D.

Dr. Willis H. Thompson, 66, assistant professor of pediatrics at the University of Minnesota, died July 24. Born in New Auburn, Wisconsin, Dr. Thompson received his medical degree from the University of Minnesota Medical School.

He was on the staffs of St. Mary's, Abbott and Swedish Hospitals and a member of the Hennepin County Medical Society, American Medical Association, American Society of Pediatrics, Northwestern Pediatric Society and an associate member of the Minnesota State Medical Association.

He is survived by his wife and six sons.

FREDERICK E. HILL, M.D.

Dr. Frederick E. Hill, 78, a former Duluth physician who practiced in the city for forty-four years, died July 19, in Riverside, California. Born in Trenton, New Jersey, Dr. Hill was a graduate of the University of Pennsylvania Medical School.

A member of the staffs of St. Luke's and St. Mary's Hospitals, Dr. Hill was also a member of the St. Louis County Medical Society, American Medical Association and a 50 Club and associate member of the Minnesota State Medical Association.

He is survived by his wife and two daughters.

JOHN A. SWANSON, M.D.

Dr. John A. Swanson, 77, St. Paul physician for twenty-eight years, died August 16 after an illness of twelve years. Born in Gull River, Minnesota, he obtained his medical degree at the Valparaiso University in Indiana and the Louisville University Medical School.

He was a member of the Ramsey County Medical Society, American Medical Association, East Side Post No. 358 American Legion and an associate member of the Minnesota State Medical Association.

He is survived by his wife.

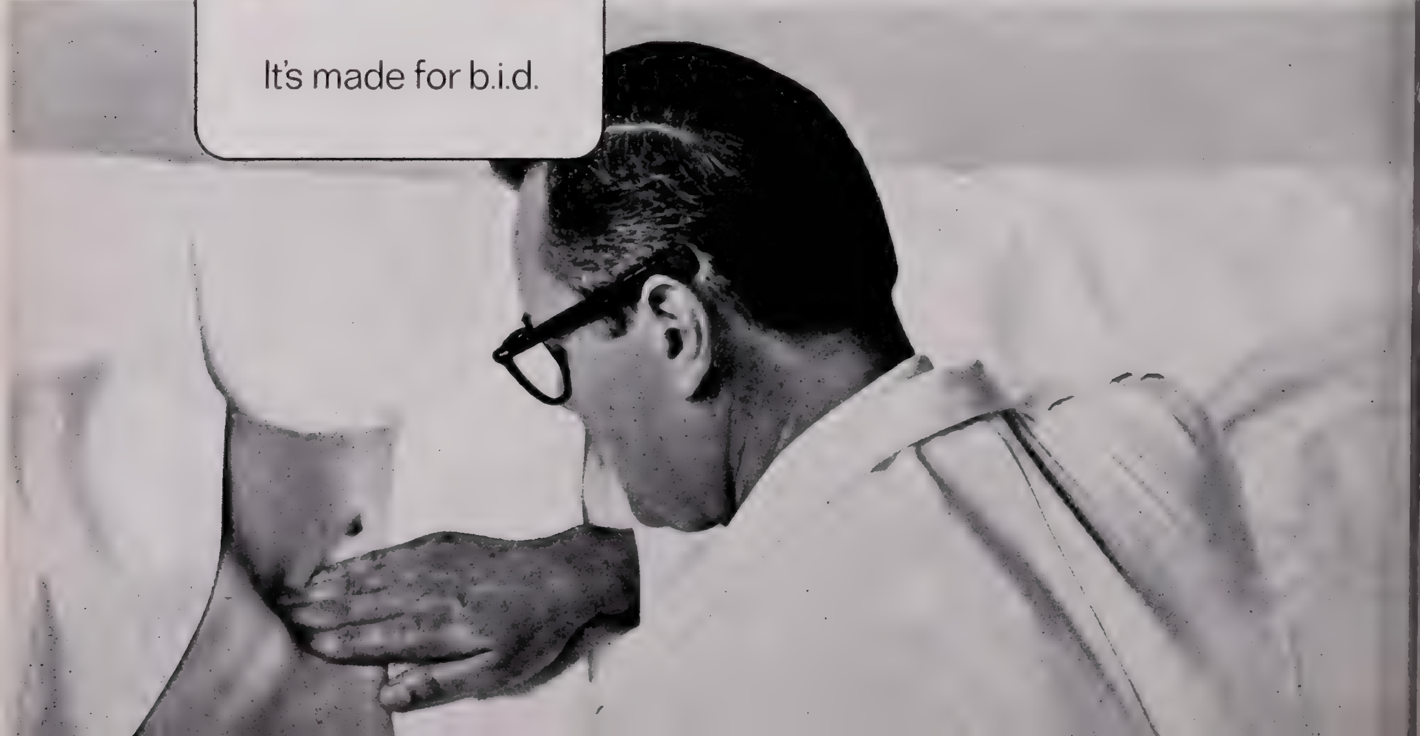
DECLOMYCIN®
DEMETHYLCHLORTETRACYCLINE

Effective in a wide range of everyday infections—respiratory, urinary tract and others—in the young and aged—the acutely or chronically ill—when the offending organisms are tetracycline-sensitive.

Contraindication—History of hypersensitivity to demethylchlortetracycline.
Warning—In renal impairment, usual doses may lead to excessive systemic accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort.
Precautions and Side Effects—Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropriate measures should be taken. Use of demethylchlortetracycline during tooth development (last trimester of pregnancy, neonatal period and early childhood) may cause discoloration of the teeth (yellow-grey-brownish). This effect occurs mostly during long-term use but has also been observed in short treatment courses. In infants, increased intracranial pressure with bulging fontanels has been observed. All signs and symptoms have disappeared rapidly upon cessation of treatment. Side reactions include glossitis, stomatitis, proctitis, nausea, diarrhea, vaginitis and dermatitis. If adverse reaction or idiosyncrasy occurs, discontinue medication and institute appropriate therapy. Anaphylactoid reactions have been reported.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should be given 1 hour before or 2 hours after meals, since absorption is impaired by the concomitant administration of high calcium content drugs, foods and some dairy products.

Capsules: 150 mg; *Tablets:* film coated, 300 mg, 150 mg, and 75 mg of demethylchlortetracycline HCl.



Medicine and Religion

Ethical Implications of Therapeutic Abortion

All ethical questions ultimately depend for answer upon the metaphysical question of the nature of values. Are values intrinsically good? Or are they extrinsically good only according to the situation in which they find themselves? Is life a value that has absolute goodness regardless of the circumstances or context in which a particular life may be found? Or is life good relative to a community of persons, things, and events which together give it value? The question of therapeutic abortion rests upon the solution of the question of value.

Usually this question is put in the form of a dilemma which is as logically false as it is practically inoperative. On one horn we find a normative, prescriptive position which may be defined in terms of either natural reason or Biblicistic rules of behavior. We may say reason assures us that human life is inviolable or the Bible says: Thou shalt not kill. Such a stand tends to become legalistic and absolutistic. Persons may be broken for principles, canons of justice may be served, but such decisions lack love. On the other horn we find a relativistic, descriptive position which says abortion is permissible if desired. This stand tends to become antinomian.* In the name of love it violates justice because in its permissiveness it becomes arbitrary. What it calls love in justification of its relativism is not really love at all. It is egocentric indulgence.

Instead of the simplistic logic of this dilemma we must look at our problem as if we had a spectrum of options, not just blacks and whites but many colors and shades. We must avoid both extremes of loveless legalism and reckless relativism. Just as the justice of absolutism ultimately fails to respect people and hence fails to do justice, so the indulgence of relativism ultimately fails to love people and leads to a fascist manipulation of life according to arbitrary standards. But if, because the situation must be considered, we reject the absolutist norm that no therapeutic abortion is licit, we must not fall into the trap of thinking the situation will tell us what to do. This is what many advocates of the so-called new morality or situational ethics do. The result is crypto-antinomianism.

It is here that our sense of value is brought to bear. The Judeo-Christian belief in the Spirit of God brings a new dimension into the discussion. Because the Spirit breathes life into man he is a creature radically different from all other creatures in quality. Man is a spirit with an eternal destiny. The breeding he gets from genetic formulae may control his mind and his pancreas and his cardiac valves, but it cannot control his spirit. Therefore it is not the situation that will determine our course of action, nor will it be an *a priori* norm, but rather it will be the Spirit speaking to us in faith as members of a community which knows itself to be the family of God destined to glorify God by serving men.

Many factors enter into the decision. First there is the guidance of the Spirit. Then there is the free, personal, responsible, and faithful choice of the individual. Doctors and patients cannot shift responsibility for decision

---

Continued

to each other or to an impersonal legal status; they must bear each other's burdens and decide with God whether the persons involved in the crisis are redeemable.

If this is the case we have an absolute in God to direct us; but his direction is never so rigid that it breaks people. There may be occasions when therapeutic abortion will be necessary, but life is still inviolable and neither mother nor fetus has preference. In a split-second crisis a doctor may have to make a choice in which he lets one person die while saving another. He cannot avoid sharing in the guilt of having to choose what he considers the lesser of two evils. He chooses bravely, knowing that his action is forgiven so long as it is done faithfully under the guidance of the Spirit and with his brothers in community. We must simply agonize in prayer to discern the guidance of the Spirit in each moment of decision.

What shall a doctor or patient do in case of rape or incest or pre-natal malformation or extra-marital pregnancy? If God is to be glorified and persons are to be served and if we are not simply to satisfy local situations or arbitrary norms, then we must ask if the persons involved are redeemable. Can we guide people caught in unwanted or dangerous pregnancy to accept their situation and creatively redeem it? Can forgiveness be brought to bear? Can the aid of the community be provided (including the technical skill of the doctor)? These questions give room for the grace of God to operate in a sinful situation. Unless we proceed on the basis of this faith we will fall into the cynicism which says abortions should be legalized because if they are not, people will seek illegal means, and it is better to have an abortion done safely than by quacks. With such a desperate argument one could legalize all kinds of murder.

It is too easy to say that abortions should be permitted because the fetus is not yet a person. The time when a fertilized ovum becomes a person cannot really be determined without being arbitrary. One can only say that we are all on our way to becoming persons from the moment of implantation until the moment of resurrection. Life begins at the juncture under the Spirit of three persons, father, mother, and child.

An extra-marital pregnancy need not destroy a marriage if there if forgiveness. A marriage threatened by extra-marital or unwanted pregnancy is not going to be strengthened by running away from the problem or blotting it out with a surgical sponge. A threat of suicide calls for more serious counselling but does not justify abortion. A new mouth to feed need not bring economic disaster if there is community concern. There are better ways of population control. Even pregnancies due to rape need not be terminated when it is considered that the child has a right to live for God's glory and that forgiveness is possible here too. The possibility of deformity may be greatly regretted, but to what extent can such deformity be predicted and to what extent can it be corrected? Here are evils, which may or may not involve guilt, but these are evils that are redeemable and should be faced with saving faith. By too hasty indulgence which masquerades as love we rob God of his grace, the community of its responsibility for social welfare, and involved individuals of their need to face sin with confession. To believe in forgiveness means not only to accept a sinful situation even if it is painful or disgraceful, but also to transform courageously that situation and the people involved into a positive good.

It would seem on the basis of this thinking that the best approach to our problem would be to bring medical science into conversation with pastoral care so that what is done with the body can be done in harmony with what is done with the spirit of persons in the community of the church. All these considerations derive from the faith that the human person is a spirit with an eternal destiny. Naturally if you reduce man to a congeries of stimuli and responses the problem will be solved differently. If, as Julian Huxley says, man is a protoplasmic agglomerate on the way to becoming fertilizer, an animated tube that runs at both ends, one will simply decide on the basis of the need for fertilizer. But if man is a spirit, then he has both freedom and responsibility and must seek to serve God and persons.

Appliance Cures

When the Austrian professor of astronomy, Hell, made his magnets in the shape of various organs in order that they might have a definite curative effect on those organs, he was taking advantage not only of the mystery of magnetism for curative purposes, but also the suggestive influence of an especially shaped appliance. Shapes have had wonderful influence on the mind of man for good or ill. A kidney-shaped magnet or one in the form of the liver or the heart would create expectancy and provide suggestion more than just a magnet of ordinary shape.

Plasters, for instance, that are employed for the purpose of affecting the kidneys favorably at many times have been shaped like kidneys. It was a rare thing to examine a patient in a New York dispensary twenty-five years ago and not find a kidney-shaped plaster sticking firmly to his back.

A favorite remedial appliance when I was a boy, for I remember them hanging in sight in the windows of the drug stores of that time, were liver pads. These were pads of various shapes and sizes containing a variety of simples, hops,* gentian,** penny-royal† and the like, which were supposed to be very efficient in stimulating the liver.

The number of wonderful cures worked by these harmless applications was without end for a time and there was an abundance of testimonials to demonstrate the fact that they had made life worth living for a great many people after it had seemed clear for years that life could never be worth while again.

Such are the ways of men and women.‡

understanding...
precedes development

The synthesis of cortisone was accomplished by Merck Sharp & Dohme in 1948—the famous "Compound E" used by Dr. Philip Hench in his historic experiment at the Mayo Clinic.

But proud as we are of our role in the development of cortisone and subsequent corticosteroids, we have continued to seek a greater understanding of arthritic disorders and new drugs for their treatment.

One such drug—INDOCIN® (indomethacin), a nonsteroid, anti-inflammatory agent fundamentally different in structure and activity from other drugs in use—was recently made available for the treatment of arthritic conditions. It opens new possibilities for the long-term management of arthritis and inflammatory disease.

MERCK SHARP & DOHME | **where today's theory is tomorrow's therapy**
Division of Merck & Co., INC., West Point, Pa.

INDOCIN®

INDOMETHACIN

Indications: Chronic and acute rheumatoid arthritis, rheumatoid (ankylosing) spondylitis, degenerative joint disease (osteoarthritis) of the hip, and gout. **Contraindications:** Active peptic ulcer, gastritis, regional enteritis, or ulcerative colitis. Safety in pregnancy has not been established. Not recommended for pediatric age groups.
Warning: Patients who experience dizziness, lightheadedness, or feelings of detachment on INDOCIN should be cautioned against operating motor vehicles, machinery, climbing ladders, etc. Use cautiously in patients with psychiatric disturbances, epilepsy, or parkinsonism.
Precautions and Adverse Reactions: Most commonly, headache, dizziness, lightheadedness, G.I. disturbances. The C.N.S. effects are often transient and frequently disappear with continued treatment or reduced dosage. The severity of these effects may occasionally require cessation of therapy. G.I. effects may be minimized by giving the drug with food or with antacids or immediately after meals. Ulceration of the stomach, duodenum, or small intestine has been reported and, in a few instances, severe bleeding with perforation and death. Gastrointestinal bleeding with no obvious ulcer formation has also been noted; INDOCIN should be discontinued if G.I. bleeding occurs. As a result of G.I. bleeding, some patients may manifest anemia, and for this reason periodic hemoglobin determinations are recommended. Rare reports of effects not definitely known to be attributable to INDOCIN include bleeding from the sigmoid colon (either from a diverticulum or without a known previous pathologic condition), perforation of preexisting sigmoid lesions (diverticulum, carcinoma), and hematuria. In other rare cases, a diagnosis of gastritis has been made while the drug was being given. One patient developed ulcerative colitis, and another, regional ileitis, while receiving INDOCIN; when the drug was given to patients with preexisting ulcerative colitis, there was an increase in abdominal pain. Infrequently observed side effects may include drowsiness, tinnitus, mental confusion, depression and other psychic disturbances, blurred vision, stomatitis, pruritus, edema, and hypersensitivity reactions. Slight BUN elevation, usually transient, has been seen in some patients, although the preponderance of evidence indicates that INDOCIN does not adversely affect renal function, even in patients with preexisting renal disease. Nevertheless, renal function should be checked periodically in patients on long-term therapy. Leukopenia has been seen in a few patients. Transient elevations in alkaline phosphatase, cephalin-cholesterol flocculation, and thymol turbidity tests have been observed in some patients and, rarely, elevations of SGOT values; the relationship of these changes to the drug, if any, has not been established. As with any new drug, patients should be followed carefully to detect unusual manifestations of drug sensitivity. Before prescribing or administering, read product circular with package or available on request.

Meetings and Announcements

My gems are falling away; but it is because God is making up his jewels. — Wolfe

SEPTEMBER

The Annual Fall Meeting of the Northwestern Pediatrics Society will be held on Friday, September 23, at the White Pine Inn, Bayport. Eldon Berglund, M.D. President.

Minnesota Society of X-ray Technologists Annual Meeting, September 30-October 1, Statler Hilton Hotel, St. Paul. Contact: Richard Board, R.T., 416 Marquette Bank Building, Minneapolis.

Second Annual Symposium on Kidney Disease sponsored by the Upper Midwest Chapter of the National Kidney Foundation, St. Paul Hilton Hotel, September 14. Contact: John M. Burns, M.D., 451 North Dunlap, St. Paul.

Scientific Meeting of the Minnesota Society of Anesthesiologists, September 23rd, Place to be determined. Contact: Van Lawrence, M.D., Mayo Clinic, Rochester.

Park Region District Medical Society, Alexandria — September meeting (date not set).

Scott-Carver Medical Society, Jordan — September 6, 7:30 p.m., Wagner's Colonial Club.

Zumbro Valley Medical Society, Rochester — September 7, 8.00 p.m., Mann Hall.

St. Louis County Medical Society, Duluth — September 8, Ex. Comm. at 6:00 p.m., regular meeting at 8:00 p.m., St. Mary's Hospital.

Camp Release District Medical Society, Montevideo — September 9, 6:30 p.m., Hunt Hotel

Wisconsin Society of OB & GYN, Marshfield, Wis. —September 9-10, Marshfield Clinic.

Minnesota-Dakota-Manitoba Orthopedic Society — September 9-10, Ambassador Motel, Minneapolis.

Medical Legal Conference, Rapid City — September 10, South Dakota.

Thirteenth Annual Internal Medicine Symposium — September 10, Iowa Methodist Hospital, Des Moines.

Minnesota Radiological Society, Brainerd Fall meeting — September 10-11, Rutger's Lodge.

Southwestern Minnesota Medical Society, Worthington, September 12, 7:00 p.m.

Twin City Urological Society, St. Paul — September 16, 6:00 p.m. Town & Country Club.

Nebraska Academy of General Practice — September 16-17, Cornhusker Hotel, Lincoln.

Iowa Chapter, American Academy of General Practice — Annual scientific sessions — September 18-19, Savery Hotel, Des Moines.

Blue Earth Valley Medical Society, Fairmont — September 21, Interlaken Golf Club, 6:30 p.m.

Wisconsin Academy of General Practice — September 25-27, Milwaukee.

Ramsey County Medical Society — September 26, 8:00 p.m., regular meeting, 15th floor, Lowry Medical Arts Building, St. Paul.

Range Medical Society — Ely, Executive and general meeting — September 27, following 7:00 p.m. dinner.

Dinner Meeting of Hennipin County Hospital Medical Staff, 6:30, September 26.

OCTOBER

Minnesota Society of Internal Medicine, St. Paul — October 17, 8:00 a.m.

Blue Earth Valley Medical Society, Interlaken Golf Club, Fairmont— October 19.

Twin City Urological Society, Town & Country Club, St. Paul — October 21, 6:00 p.m.

Quain & Ramstad Fall Clinic Conference, Bismarck, North Dakota — October 22.

Ramsey County Medical Society — October 31, 8:00 p.m. regular meeting, 15th floor Lowry Medical Arts Bldg., St. Paul.

Southwestern Minnesota Medical Society, Worthington — October 3, 7:00 p.m.

Nicollet-LeSueur County Medical Society, Holiday House, St. Peter — October 3, 6:30 p.m.

Scott-Carver County Medical Society, Wagner's Colonial Club, Jordan, — October 4, 7:30 p.m.

Hennepin County Academy of General Practice, Pick-Nicollet, Minneapolis — October 6, 6:00 p.m.

Brown County Medical Society, Dakota Hotel, New Ulm — October 11, 7:00 p.m.

Minnesota Academy of Medicine, Town & Country Club, St. Paul — October 12, 6:30 p.m.

St. Louis County Medical Society, Ex. Comm. at 6:00 p.m., regular meeting at 8:00 p.m., October 13, St. Luke's Hospital, Duluth.

PHYSICIAN UNIVERSITY HEALTH SERVICE WANTED — Younger physician for staff of outstanding university health service. Pleasant work, in close affiliation with medical school, with intelligent young adult patients. Regular hours, excellent retirement program plus social security, other liberal fringe benefits. Send resume with inquiry: Director, University of Minnesota Health Service, Minneapolis, Minn. 55455.

LARGE GROUP WITH OFFICES IN TWO CITIES is looking for General Practitioner to add to a two-man general practice clinic. Practice limited only by your abilities and interests with ready consultation from specialty partners in other office located in adjacent city. Full partnership after first year. Write: MINNESOTA MEDICINE — 358; 496 Lowry Medical Arts Building, St. Paul, 55102.

WANTED: PHYSICIAN to associate with two General Practitioners, 30 miles from Twin Cities, salary open, with early partnership. New clinic and hospital. Call 835-3129 or 835-2722, or write Doctors Clinic, Forest Lake, Minnesota.

PHYSICIAN WANTED to take over practice in the future. 7,500 population with increase of 3,000 after 3-M plant expansion. Modern, fully-equipped office with complete diagnostic equipment including X-ray and electric cardiogram. Excellent hospital facilities. Ample room for two or three doctors. Contact: E. W. Lippmann, M.D.; 26 Washington Avenue West; Hutchinson.

GENERAL PRACTITIONER WANTED for small town practice with two other general practitioners. Practice to include surgery and obstetrics within your own capabilities. Eligible for partnership after first year. Write: MINNESOTA MEDICINE — 359; 496 Lowry Medical Arts Building, St. Paul 55102.

WANTED—INTERNIST, Board certified or qualified to associate with 5-doctor clinic. In growing economy of industrial and Summer and Winter tourist area. Grand Rapids Clinic, Grand Rapids. Telephone 1-218-326-3436.

FOR RENT—Modern, air-conditioned building readily adaptable for a group of doctors or clinic located near 44th and France in highly desirable Edina-Morningside of Minneapolis. Adjacent parking. Contact owner, Ted Shirley, 926-3460.

DON'T OVERLOOK THIS . . . 3 months' rent free in modern medical clinic—successful location in N.W. suburb of Minneapolis. Come see anytime—36th and Noble Avenue North. Noble Drug, Ju 8-9449, Ben or Lou.

WANTED: OB-GYN in well established group in city of 15,000. Good hunting and fishing, we have over 1,000 lakes in county. Excellent hospital and clinic facilities. Write: V. I. Hanson, Business Manager, Park Region Medical Center, Fergus Falls, Minnesota.

FOR SALE: Prof X-ray machine (portable) price $200. My phone number is FE 8-0935, Minneapolis.

PSYCHIATRIC RESIDENCIES—positions available January and July 1967. Fully approved; balanced didactic and clinical program. Three programs from which to choose; three-year program, $8,352 to $9,500; five-year career program, $9,500-$17,184: N.I.M.H. General Practitioner stipends, $12,000. Located in Michigan's Water Winter Wonderland. Contact Dr. Paul Kauffman, Director of Training, Traverse City State Hospital, Traverse City, Michigan. An equal opportunity employer.

WANTED: a general practitioner—present physician retiring after fifty years. Good community, churches, school, stores and bank. New Hospital. Write: MINNESOTA MEDICINE-360, 496 Lowry Medical Arts Building, St. Paul.

G. P., age 31, two years experience, married with family, would like to relocate, limiting practice to medicine and pediatrics. Write: MINNESOTA MEDICINE — 361; 496 Lowry Medical Arts Bldg., St. Paul 55102.

PHARMACIST with five years' laboratory experience would like to contract pharmacy and laboratory in two or more doctor clinic. Write: Eugene Ommen, 1930 Howard Avenue, Waterloo, Iowa.

AVAILABLE SOON: Fascinating General Practice Partnership for sale in pleasant central California community just two hours from the ocean on high Sierras. Gross over $160,000 although each partner off 30% of the time in the past six years. Excellent duck, pheasant and deer hunting nearby. Profitable hospital laobratory and X-ray service included. Office conveniently located in hospital with open staff. Homes available if desired. Also, lake and ski cabin in North Shore Lake Tahoe Area. Terms negotiable near fair value. Write: MINNESOTA MEDICINE — 362; 496 Lowry Medical Arts Building, St. Paul 55102.

Ugliness

It was not until I had attended a few post-mortems that I realized that even the ugliest human exteriors may contain the most beautiful viscera, and was able to console myself for the facial drabness of my neighbors in omnibuses by dissecting them in my imagination. — J. B. S. Haldane

Virtue

Be not simply good; be good for something. — Thoreau

Medical Economics

Gifts Offer Tax Savings

We have discussed tax saving opportunities through the use of trusts, wills and marital deductions. Another avenue for estate tax and income tax savings is through the use of gifts. Present regulations permit an individual to make tax-free gifts of $30,000 *to all donees* during his lifetime without incurring gift tax liability. This is known as the "Specific Exemption." An individual may also make gifts of up to $3,000 per year *to each* donee without incurring liability. Regulations provide further that a gift made by a husband or wife may be treated, for gift tax purposes, as though made one-half by each. This provision has the effect of increasing the annual exemption to $6,000 and the "Specific Exemption" to $60,000 without gift tax liability. In order to qualify for the "Joint" treatment of gifts, both must be citizens or residents of the United States, the person making the gift must not give his wife or husband power of appointment over the gifted property, neither can they remarry during the calendar year of the gift and both must give their consent to so treating the gift.

Gifts to a spouse are also accorded special treatment. The exemption allowed is one-half the value of the property given. This exclusion is in addition to the $30,000 specific and $3,000 annual exemptions.

To illustrate the estate tax savings opportunities, assume a gross estate of $300,000, a wife and no children. The estate is to go first to the wife and upon her death to charities. If you hold all this property in your estate, the taxable estate will be $90,000 ($300,000-$150,000-$60,000) and Federal Estate Tax will be about $17,500. If, on the other hand, you give $100,000 to your wife, the estate tax will be only $4,800, an estate tax saving of $12,700. In order to qualify, these gifts must be made three years or more prior to death to avoid being held as made in contemplation of death and thrown back into the gross estate.

In this example, the transfer would require seven calendar years to avoid gift tax liability, $66,000 could be given during the first year using $33,000 marital gift deduction, $30,000 lifetime deduction and the $3,000 annual deduction. This would leave $34,000 to be gifted out during the next six years at $6,000 per year.

Using the same example, assume you have three children and intend your property to go to your wife and children. Without gift or trust provisions, the estate tax would again be $17,500, but by making gifts in trust or outright to your children of $100,000, the tax would reduce to $4,800. Such transfer would take three calendar years with $78,000 going out the first year, $18,000 the second and $4,000 the third year. To illustrate the income tax savings, assume you are in a 50% tax bracket and the $100,000 is earning $6,000 per year in dividends. You would pay $3,000 income tax on these dividends but the children will only pay approximately $700, an annual tax savings of $2,300.

The basis of property *for gift tax purposes* is its fair market value on the date of the gift. The basis of the gift *for gain purposes* is the same as the basis in the hands of the last donor who received it other than by gift. This points up an important and often neglected factor — that of keeping complete and adequate records to clearly reflect these bases. Whether you are the recipient of a gift or the donor, it is very important that you secure the data and keep a permanent record of such information for gift tax and income tax purposes.

The field of gifts is so very closely related with the use of trusts and estate planning and a decision regarding a gift must be considered from all angles. For this reason, it is important to make these decisions only upon the advice of your attorney after properly weighing all factors. Gift provisions, if used judiciously, can provide a useful avenue for tax-free transfer of sizeable amounts of property over a period of years.

William D. Huntington*
Minneapolis, Minnesota

*Northern Division Manager, Professional Management Midwest.

When you shut your eye to temptation, be sure you don't make it look like a wink. — Richard Armknecht

Sustained circulatory, respirator
and cerebral stimulation for th

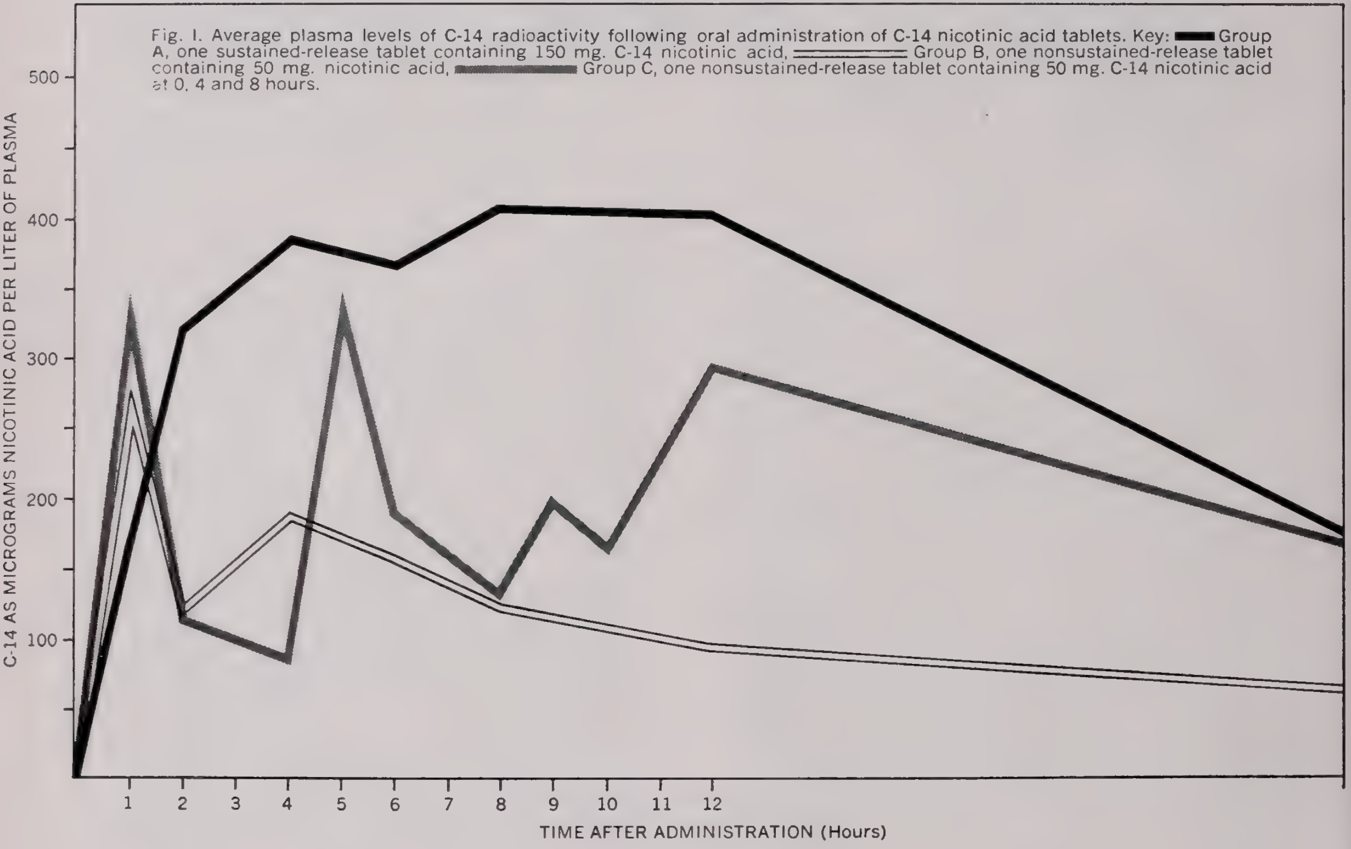

Fig. I. Average plasma levels of C-14 radioactivity following oral administration of C-14 nicotinic acid tablets. Key: ━━ Group A, one sustained-release tablet containing 150 mg. C-14 nicotinic acid, ═══ Group B, one nonsustained-release tablet containing 50 mg. nicotinic acid, ▬▬ Group C, one nonsustained-release tablet containing 50 mg. C-14 nicotinic acid at 0, 4 and 8 hours.

(fewer absent doses by absent-minded patients)

Human volunteer subjects were administered Geroniazol TT tablets with the nicotinic acid component made radioactive with C-14. Plasma and urine samples were analyzed. (See Figures I and II) The radioactive tracer study substantiated the previous clinical evidence that the release of nicotinic acid from the Geroniazol TT tablet produced a gradual rise in plasma levels to a plateau for a total of 12 hours and more.

Such proven sustained activity makes the management of geriatric patients much easier by minimizing the possibility of neglected doses through absent-mindedness or senile confusion. Therapy *can* be continuous on a daily dose of only one Geroniazol TT tablet every 12 hours.

The gradual release of nicotinic acid in Geroniazol TT will provide the well-known peripheral vasodilatation needed in patients with deficient circulation and with a minimum amount (if any) of "flushing." Also, cerebrovascular circulation is complemented by pentylenetetrazol, long-established as a cerebral and respiratory stimulant.

Geroniazol TT improves the typical, unfortunate, signs of senile confusion. Patients become more alert,

ged and debilitated

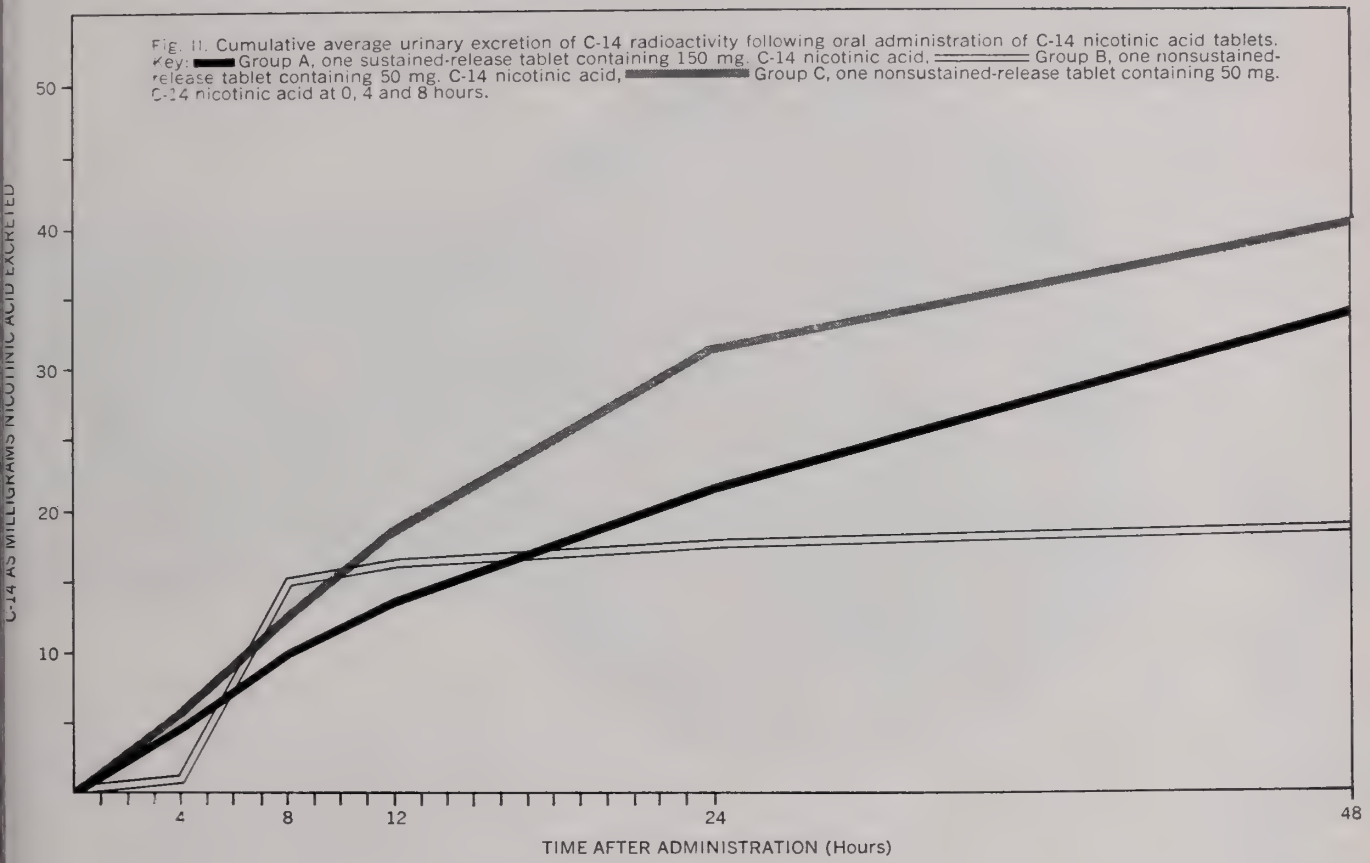

Fig. II. Cumulative average urinary excretion of C-14 radioactivity following oral administration of C-14 nicotinic acid tablets. Key: ▬ Group A, one sustained-release tablet containing 150 mg. C-14 nicotinic acid, ═ Group B, one nonsustained-release tablet containing 50 mg. C-14 nicotinic acid, ▬ Group C, one nonsustained-release tablet containing 50 mg. C-14 nicotinic acid at 0, 4 and 8 hours.

less confused and moody. Personal care, memory, emotional stability, social attention improve. Fatigue, apathy and irritability are reduced.

A prescription for 100 tablets of Geroniazol TT will permit your patients to enjoy the benefits of time-prolonged nicotinic acid/pentylenetetrazol therapy, at an economical price. Dosage is only one tablet every 12 hours.

Contraindications: There are no known contraindications.

Precautions: Exercise caution when treating patients with a low convulsive threshold.

Side Effects: Side effects are rarely encountered, however due to the vasodilatation effect of nicotinic acid, transitory mild nausea, flushing, tingling and pruritus are possible.

Dosage: One tablet every 12 hours.

Supplied: Prescribe bottles of 100 tablets, to take advantage of recent price reduction.

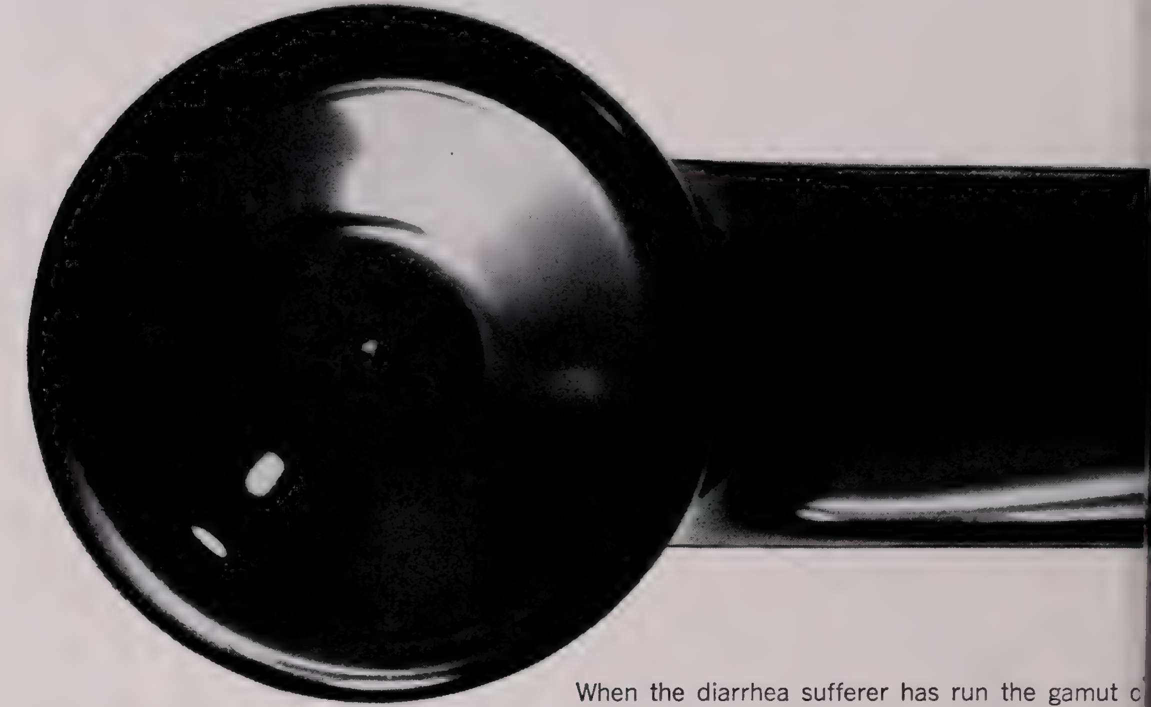
When uncontrolled diarrhea brings a call for help



When the diarrhea sufferer has run the gamut o
home remedies without success, pleasant-tastin
CREMOMYCIN can answer the call for help. It can b
counted on to consolidate fluid stools, soothe intes
tinal inflammation, inhibit enteric pathogens, an
detoxify putrefactive materials — usually within
few hours.

CREMOMYCIN combines the bacteriostatic agents
succinylsulfathiazole and neomycin, with the ad
sorbent and protective demulcents, kaolin and pec
tin, for comprehensive control of diarrhea.

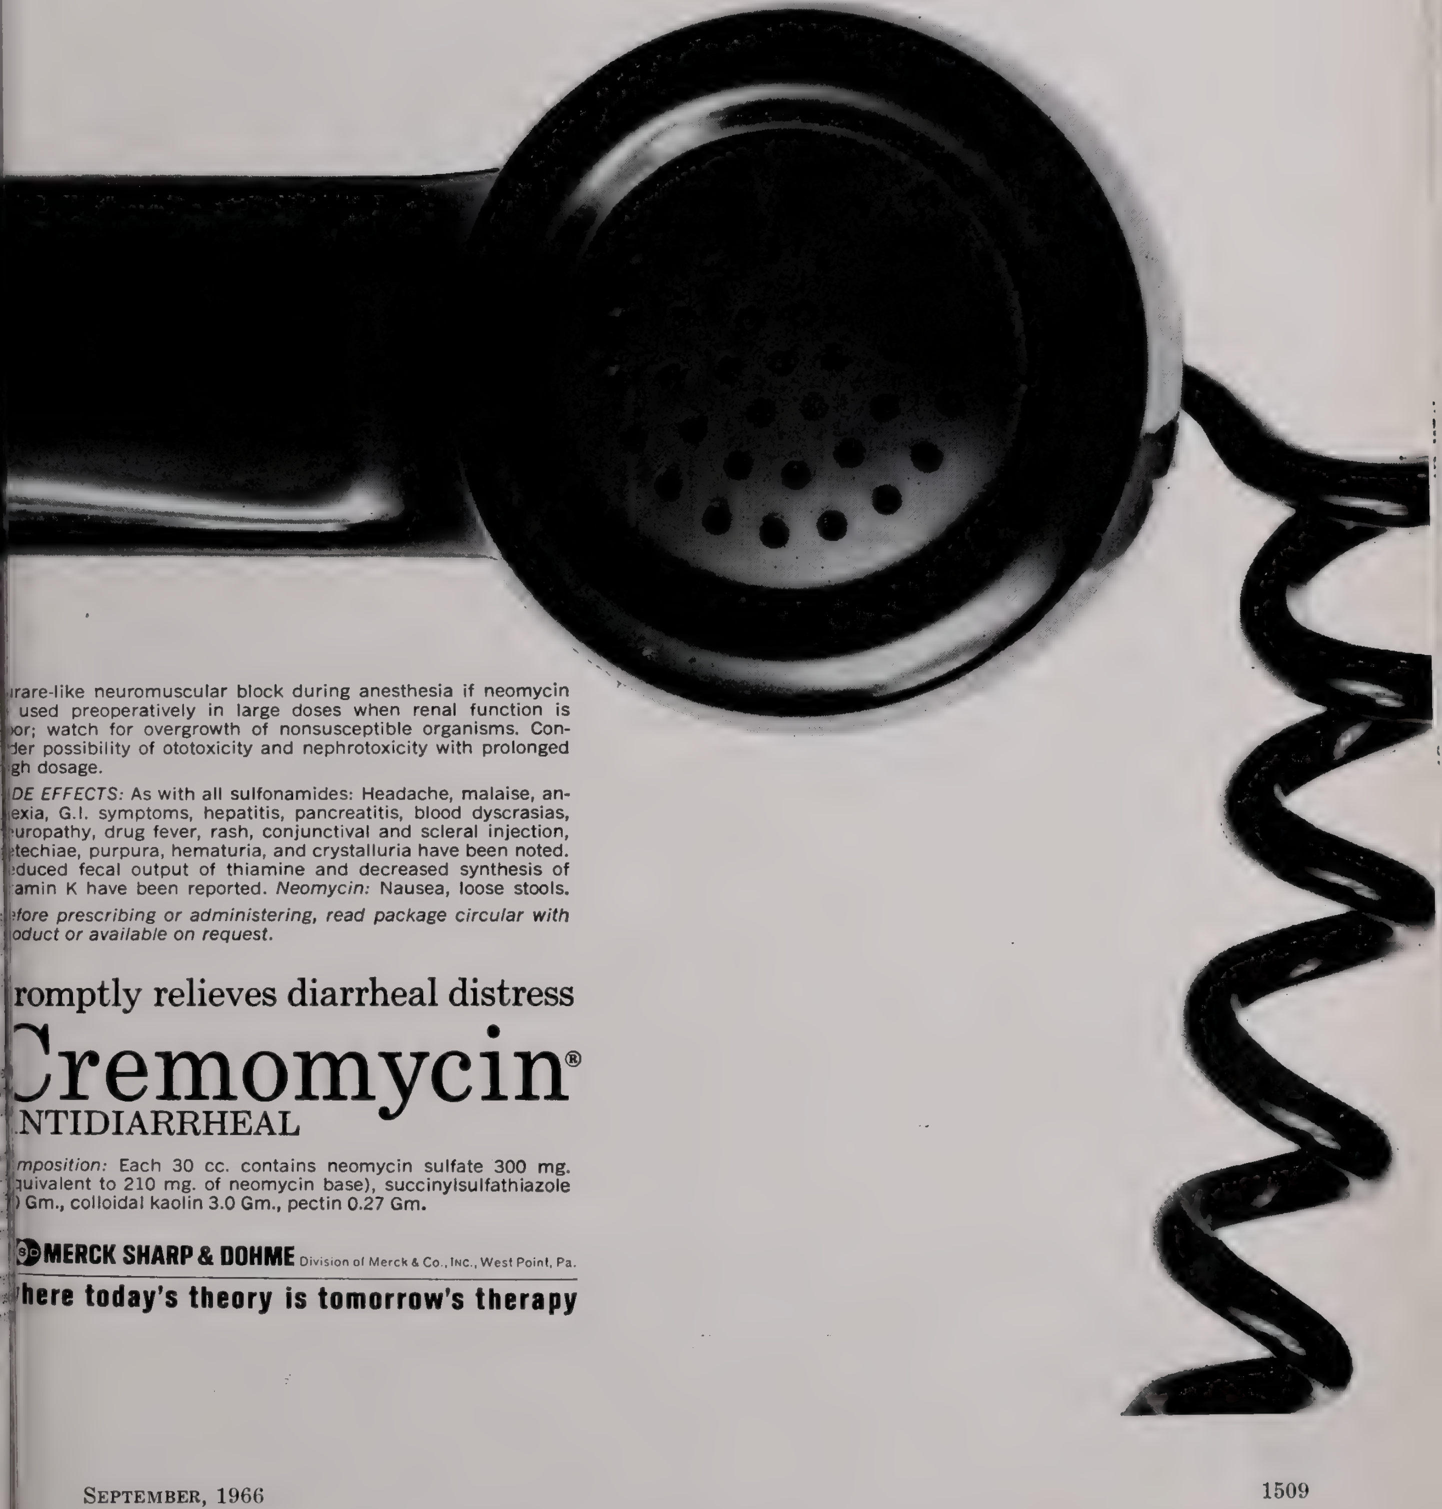
INDICATIONS: Diarrhea.

CONTRAINDICATIONS: Do not use in intestinal obstruction, e
tensive ulceration of bowel, or diverticulosis; in hypersensitivi
to sulfonamides or neomycin; in pregnancy at term, in prematu
infants, or during first week of life in the newborn.

WARNINGS: Use only after critical appraisal in patients wi
hepatic or renal damage, urinary obstruction, or blood dyscr
sias. Fatal hypersensitivity reactions and blood dyscrasias r
ported with use of sulfonamides. Consider periodic blood count
hepatic and renal function tests during intermittent or chron
use.

PRECAUTIONS: Succinylsulfathiazole: Use with caution if the
is history of significant allergies and/or asthma. Continued u
requires supplementary vitamins B_1 and K. *Neomycin:* Watch f

your ℞ for
Cremomycin
can provide relief



rare-like neuromuscular block during anesthesia if neomycin used preoperatively in large doses when renal function is or; watch for overgrowth of nonsusceptible organisms. Conder possibility of ototoxicity and nephrotoxicity with prolonged gh dosage.

DE EFFECTS: As with all sulfonamides: Headache, malaise, anexia, G.I. symptoms, hepatitis, pancreatitis, blood dyscrasias, uropathy, drug fever, rash, conjunctival and scleral injection, techiae, purpura, hematuria, and crystalluria have been noted. duced fecal output of thiamine and decreased synthesis of amin K have been reported. *Neomycin:* Nausea, loose stools.

fore prescribing or administering, read package circular with oduct or available on request.

MERCK SHARP & DOHME Division of Merck & Co., Inc., West Point, Pa.

here today's theory is tomorrow's therapy

Minnesota Medicine at a Glance

Anovulatory Syndrome — Spellacy and Cohen Page 1357

The successful treatment of the anovulatory syndrome in one instance does not constitute an assurance of the effectiveness of a drug, but since other methods of treatment are on the whole unsatisfactory, the use of Clomiphene may be worth a trial.

Large Bowel Obstruction — DeShazo et al. Page 1361

Because of the presence of air in the large bowel, as well as in the small gut, the differentiation of a large bowel obstruction from paralytic ileus may on occasions be difficult. By the process of doing a barium enema and a sigmoidoscopic examination in order to remove the distally situated gas, a differentiation can often be made. It is, therefore, well to keep this in mind in order that proper therapy can be instituted without undue delay.

Gangrene of the Foot — Loeb and Sako Page 1365

Acceleration of gangrenous changes of ischemic extremities is one of the unfavorable complications following sympathectomy. An interesting case of this paradoxical* response following lumbar sympathectomy is reported. Very careful preoperative and intraoperative studies were performed. These would indicate that the patient should expect a favorable response to sympathectomy. A possible etiologic mechanism for the unfavorable response obtained in this case is discussed.

Mitral Stenosis — Karnegis and Wang Page 1369

Mitral stenosis produces characteristic symptoms, signs, X-ray changes, electrocardiographic and phonocardiographic findings described in this paper. The formula for calculating mitral valve area from catheterization data is clearly explained. The authors present the need for accurate diagnosis and assessment of severity. They describe the Graham-Steell murmur implying relative pulmonary insufficiency. (However, when this murmur is found, usually aortic insufficiency is the cause. Ed.)

Iatrogenic Arterial Injuries — Bergan Page 1375

Galen, in the first century A.D., made reference to physician-induced arterial injury associated with blood letting. Even today inadvertent arterial injuries and complications of procedures, performed after standard methods, are noted to produce arterial injury. The author classifies and illustrates various types of arterial injuries with the use of several case reports. Awareness of the possibility of arterial injury and appreciation of the prompt treatment necessary are emphasized in this communication.

Urine Cultures in Women — Breitenbucher Page 1381

This study represents a very careful appraisal of voided "clean catch" urine cultures in women. Ninety-nine percent of the women without clinical urinary tract infections had bacterial colony counts of less than 10,000 per cc. Of those women with clinical urinary tract infections, bacterial colony counts were greater than 10,000 per cc. in 98 percent.

---

*See Test Your Word Score, Page 1411.

Ninety-three percent had more than 50,000 and 74 percent more than 100,000 bacterial colonies per cc. of urine. The author concludes that "clean catch" voided urine specimens may be reliably used for culture in women.

Regional Enteritis — Mintz Page 1437

Regional enteritis is a granulomatous disease and may occur in any portion of the gastrointestinal tract. It is most commonly observed under the age of 40. It has four major classifications which may overlap: it may develop as an acute regional ileitis; ileo-jejunitis; it may affect the colon; it may be a chronic terminal ileitis.

Regional enteritis is associated with abdominal pain, diarrhea, weight loss, fever, and occasionally an abdominal mass; and there may be anemia. Three types of fistulae may occur: internal 41%, external 22%, and perirectal 38%. Among the uncommon signs and symptoms are arthritis, ocular difficulties, erythema nodosum, and splenomegaly. The disease can be confused with tuberculosis, chronic mesenteric arterial insufficiency, carcinoid tumors of the ileum, or the irritable bowel syndrome. The diagnosis can usually be confirmed by the roentgenologic findings.

Since the treatment for this disease is not specific there are a variety of treatments designed to control the disease or its complications, and though the mortality of this disease is not relatively high, the morbidity continues to remain alarming.

Cardiac Program for Physicians

The Ramsey County Heart Division of the Minnesota Heart Association, in cooperation with the United States Department of Health, Education and Welfare, is sponsoring an on-going series of cardiac conference programs.

The programs are being held at Charles T. Miller Hospital, 125 West College Avenue, St. Paul, and is open to all physicians free of charge.

This clinical conference brings together the departments of medicine, surgery, radiology, anesthesiology, and pathology in considering interesting aspects of cardiac disease.

The conference meets every other Wednesday, alternating with the established Cardiac Pathology conference.

A complimentary buffet luncheon is served at 11:45 a.m. in College Hall at the Charles T. Miller Hospital, and the lectures and conferences are held from 12:30 p.m. to 1:30 p.m., in the College Hall amphitheater.

For more information call the Minnesota Heart Association, 646-6554. Advance reservations are unnecessary.

It is only by medicine that one can arrive at some knowledge of human nature, — but on one condition, to embrace it in its true generality. — Hippocrates

Benadryl®
(diphenhydramine hydrochloride)
PARKE-DAVIS
for control of allergic symptoms

Whether the allergen is red and round, or unseen and unknown, BENADRYL provides relief of symptomatic distress through its antihistaminic and antispasmodic actions. *PRECAUTIONS:* Persons who have become drowsy on this or other antihistamine-containing drugs, or whose tolerance is not known, should not drive vehicles or engage in other activities requiring keen response while using this product. Hypnotics, sedatives, or tranquilizers if used with BENADRYL should be prescribed with caution because of possible additive effect. Diphenhydramine has an atropine-like action which should be considered when prescribing BENADRYL. *SIDE EFFECTS:* Side reactions, commonly associated with antihistaminic therapy and generally mild, may affect the nervous, gastrointestinal, and cardiovascular systems. Most frequent reactions are drowsiness, dizziness, dryness of the mouth, nausea, and nervousness. BENADRYL is available in Kapseals® of 50 mg. and Capsules of 25 mg. 00666

A RELIABLE, PROVEN PRODUCT . . .

The BSP test, introduced in 1925, remains one of the most sensitive laboratory procedures available for determining hepatic function.

A STERILE, CONVENIENT PUT-UP . . .

Each BSP Disposable Unit contains: a sterile, glass, disposable syringe with the 5 mg./kg. BSP dosage schedule imprinted on the barrel, a sterile needle, alcohol swab and a 7.5 ml. or 10 ml. size ampule of Bromsulphalein.

The BSP unit is designed for maximum patient protection. The precalibrated syringe makes weight calculations unnecessary and provides for proper dosage regardless of patient-weight.

ECONOMICALLY PACKAGED . . .

Prepared for economic unit dispensing, this completely disposable put-up affords a savings in time and labor—the most costly commodities.

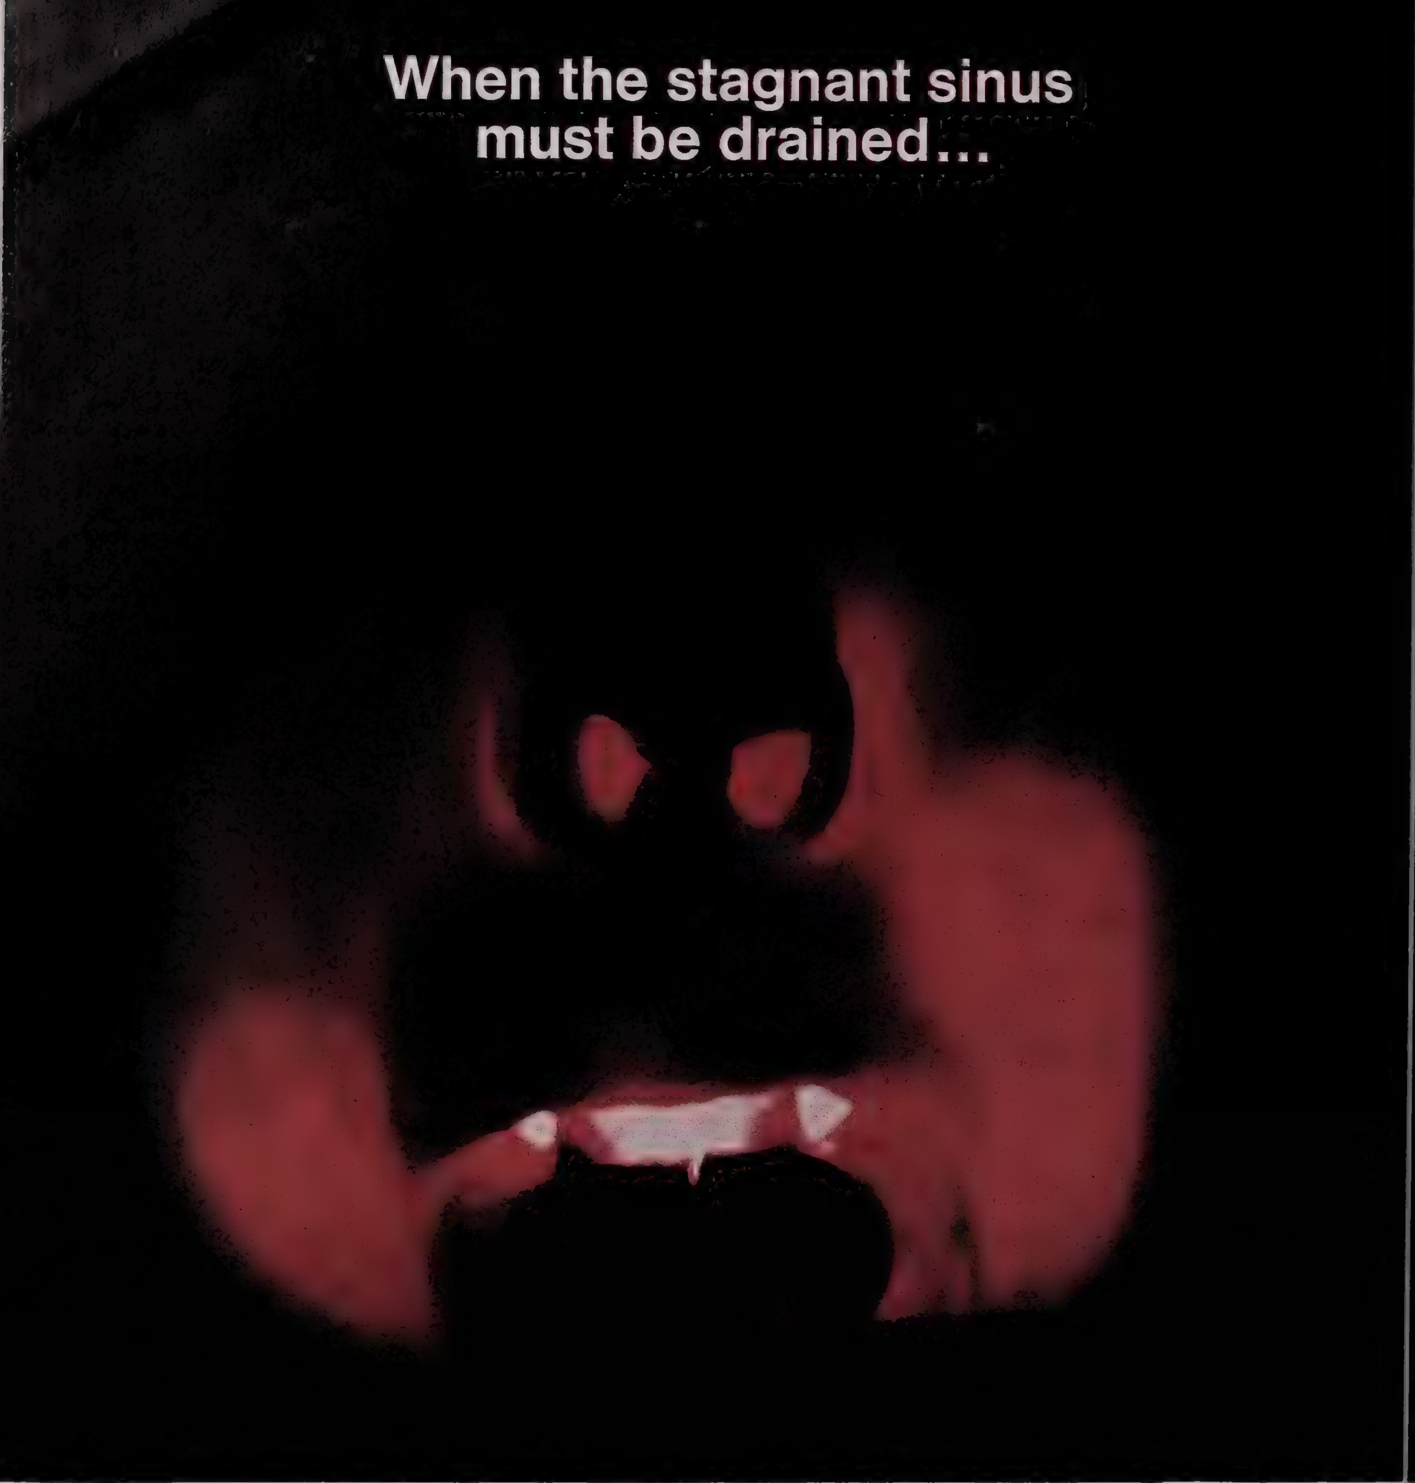
When the stagnant sinus must be drained...



Transillumination of the sinuses—diffuse shadow on right side of face indicates unilateral maxillary sinusitis.

In the common cold, Neo-Synephrine is unsurpassed for reducing nasal turgescence. It stops the stuffy feeling at once. It opens sinus ostia to re-establish drainage and lessen the chance of sinusitis. With Neo-Synephrine, in the concentrations most commonly used, decongestion lasts long enough for extended breathing comfort, without endangering delicate respiratory tissue. Systemic side effects are virtually unknown. There is little rebound tendency.

Winthrop Laboratories, New York, N.Y. 10016 **Winthrop**

Neo-Synephrine® HCl

Brand of phenylephrine hydrochloride

is available in a variety of forms, for all ages:

1/8% solution for infants
1/4% solution for children and adults
1/4% pediatric nasal spray for children
1/2% solution for adults
1/2% nasal spray for adults
1/2% jelly for children and adults
1% solution for adults (resistant cases)

Also NTZ® Solution or Spray
Antihistamine-decongestant

(1025M)

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Readers and Reviewers

Equip your ICU with the exact monitoring capabilities you need

You can have a system "tailored" to your needs — *using standard HP Sanborn monitoring modules* — whether it involves a few conditions for a few patients . . . or many patient conditions, eight or more beds, and complete central station alarm/display/recording facilities. Start with 780-series modules for monitoring the ECG and heart rate, for example (shown above), and as needs and budget enlarge, add "780" modules to monitor more functions, more patients or both. (Illustration below shows the addition of temperature, respiration rate, systolic and diastolic pressure monitoring functions, plus pacemaker, to the original two functions.) System suitability, economy, future functional and location adaptability, and rapid staff training are the continuing benefits of modular "780" systems.

Specific capabilities of these units, in addition to those mentioned, include venous pressure monitoring . . . internal/external DC defibrillation . . . and continuous ECG recording on endless loop magnetic tape units, with automatic readout on alarm of data immediately preceding distress condition. Wall Mount Brackets are available to free space around beds, or two styles of "780" carts give complete instrumentation mobility. For Central Station use, a wide choice of units is available for visual display, audible alarm, signal switching, graphic and tape recording.

When complete cardiac function monitoring is needed, with automatic ECG recording at selected intervals or on distress, the 780B Viso-Monitor provides it in a single bedside unit. Indicators display heart rate, QRS event, bradycardia, tachycardia, pulse loss and arrest; internal/external pacemaker is built in. Companion unit supplies visual display and audible alarm of all conditions monitored by the Viso-Monitor.

HP/Sanborn field offices can give you valuable help in system planning, installation and staff training — and provide continuing, local service. For details, send the coupon to Hewlett-Packard Company, Sanborn Division, Waltham, Mass. 02154. In Europe, H.P.S.A., 54 Route des Acacias, Geneva.

President's Letter

At a recent meeting of the Organization of State Medical Association Presidents, a group which includes presidents elect and immediate past presidents as well, the multiple problems involving state associations uniquely different from the over-all involvement of the American Medical Association were the basis of the two-day session.

Ohio's problem with the Statement of Compliance, New York's experience with the implementation of Title XIX, multiple state concern with the problems of the in-hospital specialist were among the topics of the meeting.

Representatives of the Department of Health Education and Welfare appearing before the group reviewed current government regulations, discussed areas of apparent misunderstanding and explored probable areas of expanding Federal involvement in the practice of medicine and the development of medical man power.

Most of the problems reported by various States were common to all states, and while the Organization has no structure or authority to develop corrective measures as an organization, the exchange of ideas and suggestions and the full reporting of intrastate action where action was required constituted valuable experience for every state officer in attendance.

We physicians in Minnesota, however, have a different problem. Our problem has no governmental overtones, no patient-physician relationship, no assignments to sign or not to sign, a problem where participation is not debatable but is a must. This problem is the handicap under which our Association office operates. When the volume of work is weighed against the deficiencies of the office space in which it is produced, the number of workers who produce it and the continuing high quality of the result, those results seem incredible. Only dedication can explain the efficiency with which rapidly increasing demands are being met. Since there is no foreseeable end to these increasing demands, but since human dedication has an ultimate limit, our problem becomes obvious.

A committee Council appointed has been considering new physical arrangements ranging from renting to building. The House of Delegates, in approving a dues raise, considered and approved the need for increased sums to be spent on personnel additions. Combining these two actions, expediting a committee decision, proposing the project with a sound financial base to the Association as a whole must be a high priority Association activity.

Our other problems are many, but this present need, when met, will provide the mechanisms needed for a wider physician understanding of the problems, better physician-association rapport and better lives for our overburdened, highly efficient and loyal staff.

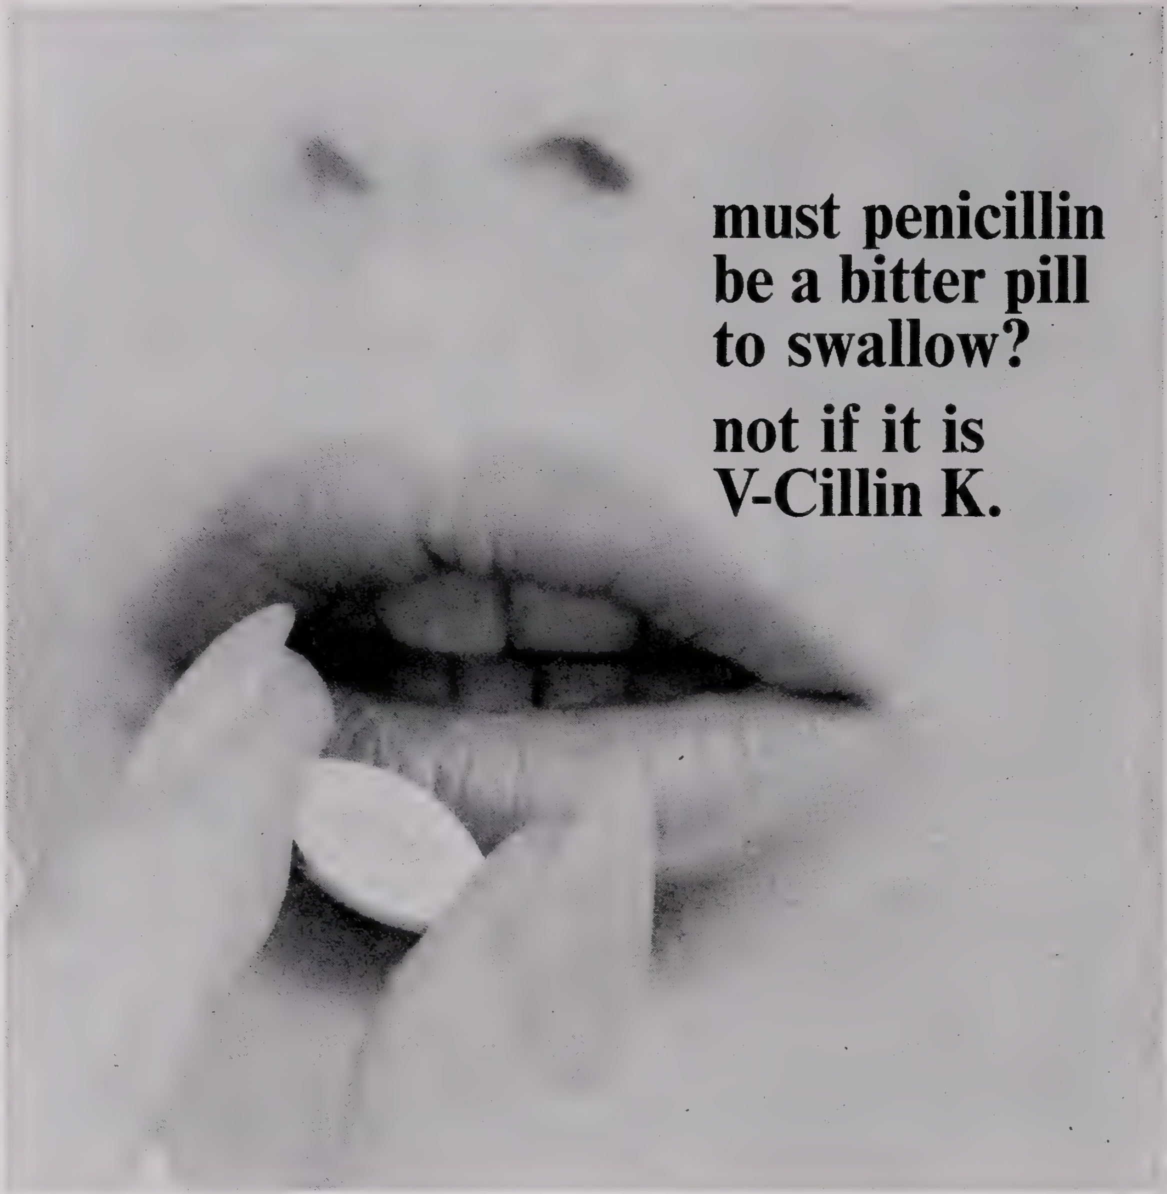
R. P. Buckley, M.D.
President
Minnesota State Medical Association



must penicillin be a bitter pill to swallow?
not if it is V-Cillin K.

V-Cillin K now has a unique glossy coating that banishes bitter penicillin taste and makes it easier to swallow. Within six seconds (just long enough for the tablet to get past the taste buds), the coating dissolves and the penicillin is ready for immediate absorption into the bloodstream. The patient still gets all the special benefits of V-Cillin K, including consistent dependability . . . even in the presence of food.

Indications: V-Cillin K is an antibiotic useful in the treatment of streptococcus, pneumococcus, and gonococcus infections and infections caused by sensitive strains of staphylococci.

Contraindications and Precautions: Although sensitivity reactions are much less common after oral than after parenteral administration, V-Cillin K should not be administered to patients with a history of allergy to penicillin. As with any antibiotic, observation for overgrowth of nonsusceptible organisms during treatment is important.

Usual Dosage Range: 125 mg. (200,000 units) three times a day to 250 mg. every four hours.

Supplied: Tablets V-Cillin K, 125 or 250 mg., and V-Cillin K, Pediatric, 125 mg. per 5-cc. teaspoonful, in 40, 80, and 150-cc.-size packages.

V-Cillin K® **Six-Second Barrier to Bitterness**

Potassium Phenoxymethyl Penicillin

The Case for Body Surface Area

As A Gauge for Drug Dosage

W. D. SNIVELY, JR., M.D.*
Evansville, Indiana

"Dosage is the heart of drug therapy. It is therapy in action. Right or wrong, it is the final expression of diagnostic and therapeutic acumen." *Harry C. Shirkey, M.D.*

SHIRKEY'S EMPHASIS on the importance of proper drug dosage is most timely. Modern drugs are among the physician's most powerful weapons against disease. Properly aimed, they are strikingly effective. Improperly aimed, they fail to hit the target, accomplishing nothing; worse, they may do harm.

Drug dosage deserves particular attention in pediatrics, because many childhood diseases are so acute, because children vary greatly in their susceptibility to potent agents, and because most pediatric doses represent casually or inaccurately derived fractions of adult doses.

Age as a Gauge

Not only is age of little worth as a gauge for dosage; it presents real hazards since it may yield an inadequate dose at a time of critical need or an overdose that may poison. Its unreliability stems chiefly from the great normal variations in size within a given age group. For example, a six-month-old infant girl may weigh from 12.7 to 20 pounds and still be normal. At 12 years of age the normal maximal weight is double the normal minimal weight. Such variations make age a highly unreliable criterion for dosage.

To compound the inaccuracy, ages are often bracketed arbitrarily for dosage purposes. For example, the ages from two to six years may be placed in one group; the ages six to 12 years in another group. A six-year-old could fall into either group. The two-year-old will probably get an overdose, the twelve-year-old an underdose. Shirkey[25] found that the maximal dose based upon such a vague recommendation could be 666% of the minimal dose. He therefore concluded, "Only honey or non-medicated syrups should be dosed according to age."

Weight as a Gauge

While weight surpasses age as a gauge for pediatric drug dosage when applied to infants and children of about the same age, it is not reliable when applied to patients of different ages since the dose of most drugs is not a simple linear function of body weight. Hence, dosing on the basis of so much per kilogram body weight can cause gross inaccuracy. Using weight as the gauge, the correct dose for an infant or small child will usually be excessive when applied to a larger child or to an adult. For example, the recommended daily dose of sulfadiazine for the older infant is 150 mg./kg. If this is used as a basis for calculating the dose for an adult, it results in the administration of 10.5 Gm./day instead of 6 Gm./day, the recommended dose for an adult.

Valiant attempts have been made to correct for the unreliability of dosage based on weight. They have resulted in arbitrarily chosen categories with a different per-weight unit for each category. As will be shown below, such dosage schedules overtax the memory. They force physicians to rely on schedules printed on blotters, cards, calendars, and other give-aways. They shackle the physician to memory aids except in the case of simple drugs that he uses frequently.

Body Surface Area as a Gauge

A rich body of scientific evidence has demonstrated a rough quantitative relationship between body surface area and such fundamental physiologic measurements and processes as heat production, cardiac output, plasma volume, glomerular filtration, blood pressure, organ size, oxygen consumption and nitrogen requirement.[2,3,4,5,6,7,8,9,10,13,14,18,21] On the basis of this relationship, one can reasonably suppose that the magnitude of the individual's physiologic struggle to maintain life can be measured by the area of his exposure to the external environment. The several systems of the body support the individual in that struggle. The area of the body surface, therefore, provides a useful index of the activities of the body systems. As an example, requirements for water and electrolytes have been shown to be roughly proportional to body surface area.[12,15,22,23] So have the optimal doses of drugs in therapy.[16,24,25,27,28]

We can well ask: "Why is body surface area the best measurement on which to base dosage?" The reason relates to our ancestral Protozoan, whose cell membrane was a versatile, all-important structure directly concerned with the functions of nutrition, circulation, excretion, respiration, and locomotion. With the coming of multicell organisms, functions became localized and special structures were evolved to perform them. For example, the digestive tract began as an external surface lined with endodermal cells. Then invagination occurred. The end result was an elongated digestive tube closed except for openings at the head and tail of the organism. Other functions were taken over by appropriately specialized organs.[23]

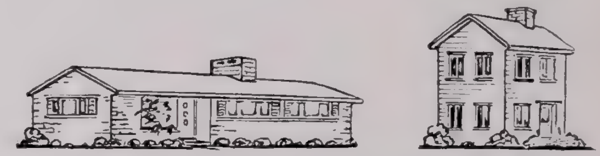

Fig. 1 — The elongated ranch house has more surface area in relation to volume than does the two story conventional house.

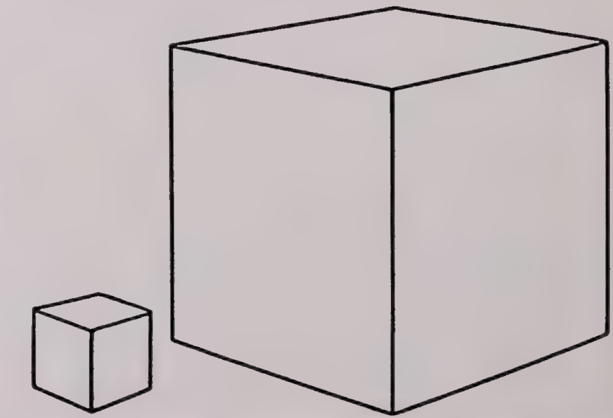

Fig. 2 — Ratio of surface area to volume of the small (2 in.) cube is 3:1. Ratio of surface area to volume of the large (8 in.) cube is .75:1.

Yet with all the progress made by mammals toward complexity and specialization of function, the mammalian body surface still corresponds anatomically to the cell membrane of the Protozoan. Because of this correspondence, body surface area provides a quantitative, though approximate, index of our total metabolic activity. Thereby it provides us with a remarkably useful gauge for dosage.

In 1950 Crawford and others[16] described how the surface area principle could simplify dosage. They used body surface area as the common denominator in the calculation of doses of a large variety of drugs for more than a year for patients ranging from small prematures to young adults. Their clinical results suggested that body surface area offers greater simplicity and accuracy than do calculations based on age or weight. Since their paper appeared, body surface area has been taught as a gauge for dosage in more and more medical schools. Leading textbooks in the field of pediatrics present drug doses in terms of surface area as well as in terms of weight.[24,27] The current dose recommendations from the Children's Service, Massachusetts General Hospital, gives drug doses chiefly in terms of surface area.[29] Surface area as a gauge for dosage has the authoritative support of the Council on Drugs of the American Medical Association.[28] Subscribers to the National Formulary XII, published in September, 1965, received a handbook on Drug Dosage[26] with each copy of the Formulary. The handbook gives doses in terms of surface area, thus making available the surface area method to every pharmacy school, most pharmacy graduates, and countless laboratories and libraries.

Relation of Surface Area to Weight, Volume, and Configuration

The shape and dimensions of an object determine the ratio of its surface area to its weight or volume. An elongated object has more surface area in relation to volume than does a squarish object of equal volume. Thus, a single story, modern ranch house with dimensions 50 × 25 × 10 ft. has a volume of 12,500 cu. ft. Its surface area is 4,000 sq. ft. An old-fashioned conventional style house with dimensions of 25 × 25 × 20 ft. has a volume of 12,500 cu. ft. and a surface area of only 3,250 sq. ft. Because of its smaller surface area such a house would be more appropriate for cold climates because it would be easier to heat. See Figure 1.

A small object has a relatively larger surface area than does a larger object. Thus, a 2-inch cube has a volume of 8 cu. in. and a surface area of 24 sq. in. The ratio of

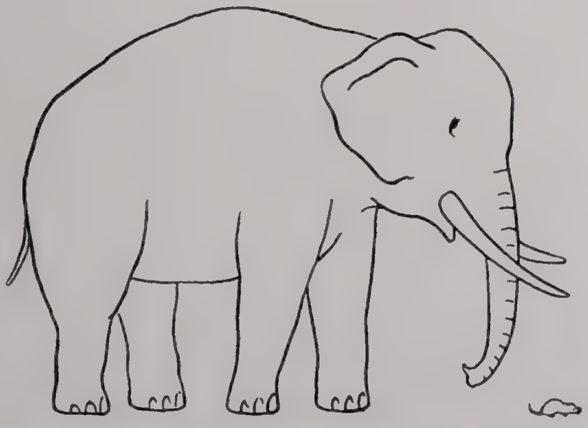

Fig. 3 — The shrew has approximately 42 times as much surface area in relation to weight as does the elephant.

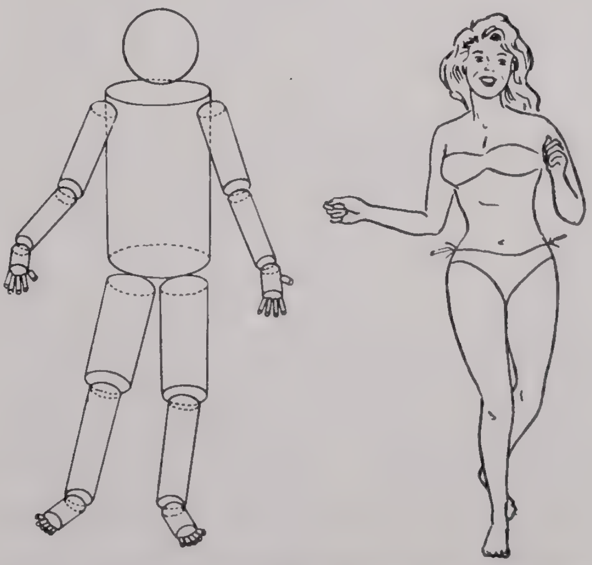

Fig. 4 — Mathematically the human body resembles a series of cylinders topped by a sphere.

surface area to volume is 3:1. An 8-inch cube has a volume of 512 cu. in. and a surface area of 384 sq. in. The ratio of surface area to volume is .75:1. See Figure 2.

The mathematical explanation for these relationships is that surface area increases or decreases as the square of linear dimensions while weight or volume increases or decreases as the cube of linear dimensions.

A small object has a greater surface area in relation to its weight or volume than does a large object. Thus a shrew weighing 60 Gm. has 42 times as much surface area in relation to weight as does an elephant weighing 5,500,000 Gm. See Figure 3.

Similar relations apply to round or curved objects such as the human body, which, reduced to its geometric elements, resembles a series of cylinders topped by a sphere (admittedly an inappropriate description for a pretty girl). See Figure 4.

How to Determine Body Surface Area

Undoubtedly the difficulty involved in measurement of body surface area explains why it has not been more generally used. Methods used by investigators have involved simple covering, geometrical measurement, measurement of the skinned hide, photographing the silhouette, measurement of electrical currents, and so forth. Such methods are obviously impractical for everyday use. Hence, formulas based upon height and weight were devised for estimating the approximate body surface. These formulas were incorporated into nomograms* including those of DuBois[2,11,17,19] and somewhat refined nomograms developed by Sendroy.[20] Obviously, one must know the height and weight of the patient and in addition have a nomogram available if this method is to be used. But heights and weights are not always known or are not always procurable and nomograms can be lost. The West table, which permits one to determine body surface area on the basis of weight alone, has been recommended by Shirkey and Barba.[24] It is most reliable when used for children of approximately normal body configuration. The author and his colleagues[30] estimated the surface areas of 266 children by use of the West table and the Sendroy nomogram. Statistical comparison of the results of the two methods showed a standard deviation of 11.45%, satisfactory for clinical purposes. They developed an alternative method requiring nothing but a tape measure. It utilizes the sitting height (crown-rump length) method through use of a formula. For children *six months and under* one uses the formula:

$$\text{Surface area} = 0.00017\ (\text{sitting height in cm.})^2 {}^{**}$$

For children *over six months* one uses the formula:

$$\text{Surface area} = 0.00019\ (\text{sitting height in cm.})^2$$

Results derived by the sitting height formula were compared statistically with those found by use of the Sendroy nomogram. The standard deviation for children six months and under was 6.66%; for children over six months the standard deviation was 7.55%.

The rationale for the sitting height formula rests on the accepted theory of the origin of man and provides evidence supporting that theory. Examination of the formula reveals that surface area is proportional to the square of the sitting height. Why should this be? Man's ancient aquatic ancestor was a worm-like creature not too unlike Amphioxus. It had a straight gut running the length of its body. The length of the gut was, of necessity, proportional to the length of the body. As evolution occurred over countless millenia, multiples of this proportion were maintained, even though the gut became convoluted and elongated to the point that it was many times the length of the body.

Today, for a given species, the length of the gut is still proportional to the length of the body. Now the measurement of man that corresponds to the body of his ancient ancestor is not his *total length* or *height* but his *crown-rump length* or *sitting height*. Arms and legs, it must be recalled, are phylogenetically not part of body length, but are lateral extensions of the body, originating in the fins of the Crossopterygian, the first fish to come ashore.

---

*See Test Your Word Score, Page 1573.

**The expression (sitting height in cm.)^2 means the square of the sitting height measured in centimeters.

While the length of the gut is proportional to the sitting height, the area of the gut is proportional to the square of the sitting height. Von Pirquet explained why this is so.[1] He cited the work of Henning who found that the length of the intestinal canal on an average equals ten times the sitting height. "Direct measurements of the surface of the intestines gave for the undilated canal of an adult about 5000 sq. cm.; for the dilated, about 10,000 sq. cm.: if we take a medium of 7500 sq. cm., this corresponds to an average circumference of about one tenth of the sitting height. We can, therefore, have a conception of the absorbing surface in multiplying ten times the sitting height by one tenth of the sitting height, or, in other words, we take the square of the sitting height as a symbol of the absorbing surface."

Since the gut originated as an invagination or infolding of the body membrane of the Protozoan, I reasoned that the sitting height squared might well be proportional to body surface area. Simple arithmetic comparisons and, later, computer analyses, showed this to be the case.

While the simple West table for derivation of surface area by weight alone is widely useful and while it meets most needs for determination of surface area, the sitting height formula has the following possible uses:

1. It can be used as the chief method of determining body surface area when the weight is not known or not obtainable. It should thus prove useful in emergency situations and in developing countries.
2. It can be used when weight or a weight-surface nomogram or both are not available.
3. It can be used to check the value for surface area arrived at by other methods.

Limitations of Body Surface Area

While body surface area is undoubtedly the best single gauge for dosage, it should not be the sole gauge in dosing neonates and premature infants. For these no rule, however general, suffices. Doses must be individualized if they are to meet the needs of the infant for the situation in question. Indeed, use of body surface area for older infants and children really provides only an initial dose — and, of necessity, an *average* initial dose, that must be modified and adjusted later in accordance with the individual tolerance, requirement and clinical progress of the patient.

While body surface area appears to be the best gauge for dosage for adults as well

TABLE 1
Equivalent Sheet

Weight in Pounds	Sitting Height in Centimeters (crown-rump length)	Body Surface Area (square meters)	Single Dose of Liquid Pediatric Pharmaceuticals (in milliliters)
4.4	30	0.15	1.5
8.8	36	0.25	2.5
13.2	44	0.33	3.3
17.6	46	0.40	4.0
22.0	49	0.46	4.6
33.0	58	0.63	6.3
44.0	66	0.83	8.3
55.0	71	0.95	9.5
66.0	75	1.08	10.8
77.0	79	1.20	12.0
88.0	83	1.30	13.0
99.0	86	1.40	14.0
110.0	89	1.51	15.1
121.0	91	1.58	15.8

TABLE 2
Dose Instructions for REX®*
Give 4 times daily the dose corresponding to the figure closest to the child's weight or sitting height

Weight (in kg.)	Sitting Height (in cm.)	Body Surface Area (in M^2)	Dose of REX® (in ml.)
4	36	0.25	2.5
8	46	0.4	4.0
15	57	0.6	6.0
20	64	0.8	8.0
30	75	1.0	10.0
35	79	1.2	12.0
45	86	1.4	14.0
55	92	1.6	16.0

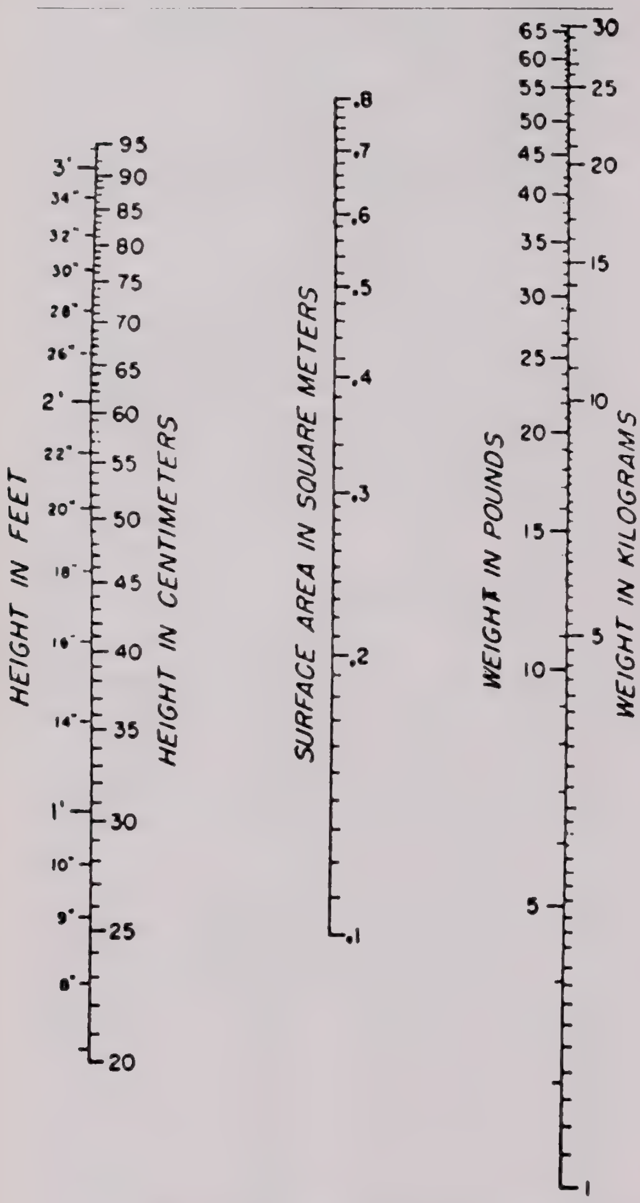
Calculations showing conversion of weight or sitting height to body surface area are not shown, but by using weight or sitting height to determine body surface area you can dose with great simplicity and accuracy.
For children with extremely unusual body configurations use a surface area nomogram or calculator, which utilizes height and weight to determine body surface area. Note that the basic dose for REX® is 10 ml. per M^2 body surface area four times daily.

---

*REX® is an imaginary product.

as for children, we have tested the validity of the weight conversion nomogram (West table) and the sitting height formula statistically only in infants and children. Even in the case of infants and children, those with unusual body configuration might well have their surface area measured by use of the DuBois or Sendroy nomograms.

TABLE 3



Body Surface Area Nomogram for Infants and Young Children

To determine the surface area of the patient draw a straight line between the point representing his height on the left vertical scale to the point representing his weight on the right vertical scale. The point at which this line intersects the middle vertical scale represents the patient's surface area in square meters.

Body Surface Area in the Dosing of Electrolytes

Body surface area as a gauge for dosage has, as noted above, enjoyed wide use in calculating doses for water and electrolytes. Its superiority over the use of body weight or age can be seen readily, since requirements for these substances when expressed in terms of body weight vary greatly from one age group to another. Thus the young infant has an average water intake of 70 ml./lb., while that of the ten-year-old is 35 ml./lb., and that of the adult, 25 ml./lb. Similarly, the infant has an average intake of 1.3 mEq. of sodium per pound compared to an average of 0.8 mEq. per pound for the ten-year-old and 0.5 mEq. per pound for the adult. But the average daily maintenance requirement for water is 1500 ml./M^2/24 hrs. regardless of age. The average daily maintenance requirement for either sodium or potassium is 50-70 mEq./M^2/24 hrs. These values apply to individuals of all ages. Even the maintenance requirement for carbohydrate can be expressed in terms of body surface: the average daily maintenance requirement is 60-75 Gm./M^2/day.

Iron, while not ordinarily considered an electrolyte, can also be dosed by use of body surface area. Consider the recommendations for dosage of a ferrous sulfate drop preparation, Fer-In-Sol^R, for prevention of iron deficiency when age groups are used as a dosage gauge:

Infants and young children	0.3 ml.	(Provides 7.5 mg. iron)
Older children	0.6 ml.	(Provides 15 mg. iron)

Such dosage can be simplified by using body surface area as the dosage gauge, in which case the dose becomes:

0.6 m./M^2/24 hrs. (Provides 15 mg. iron)

Consider the treatment of iron deficiency anemia when age is used as a gauge:

Infants	4-5 doses of 0.6 ml.	(Provides 60-75 mg. iron)
Children 2 to 6	5-7 doses of 0.6 ml.	(Provides 75-105 mg. iron)
Older children	7-10 doses of 0.6 ml.	(Provides 105-150 mg. iron)

How much simpler merely to use:

6 ml./M^2/24 hrs. (Provides 150 mg. iron)

Body Surface Area in the Dosing of Pediatric Pharmaceutical Products

We will confine our discussion of the use of body surface area as a gauge for dosage to pediatric pharmaceutical products, since it is for such products that surface area sees its greatest usefulness. Obviously, the more potent the drug to be used, the more critical is the dosage. Yet accuracy in dosage is desirable even for relatively innocuous drugs if one is to achieve the maximal results without side reactions.

The application of surface area can be demonstrated by examples. First, let us consider liquid products:

TEMPRA® Syrup and Drops

Using age as dosage gauge:

Age (Years)	*Doses 3-4 times daily* *Drops*	*Syrup*
Under 1	0.6 ml.	½ teaspoon
1 to 3	0.6 to 1.2 ml.	½ to 1 teaspoon
3 to 6	1.2 ml.	1 teaspoon
6 to 12	2.4 ml.	2 teaspoons

Using body surface area as dosage gauge:

8 ml./M^2/24 hrs.	33 ml./M^2/24 hrs.
Divided into 3-4 doses	Divided into 3-4 doses

MERCUHYDRIN® sodium

Using weight as dosage gauge:

Below 3 kg. — 0.125 ml.
3- 7 kg. — 0.25 ml.
7-15 kg. — 0.5 ml.
15-25 kg. — 0.75 ml.
25-35 kg. — 1 ml.

Using body surface area as dosage gauge:
1 ml./M^2/24 hrs.

QUIBRON® Elixir

Using weight in relation to age as dosage gauge:

Children under 6 — ½ teaspoon per 10 lbs. of body weight two or three times daily.

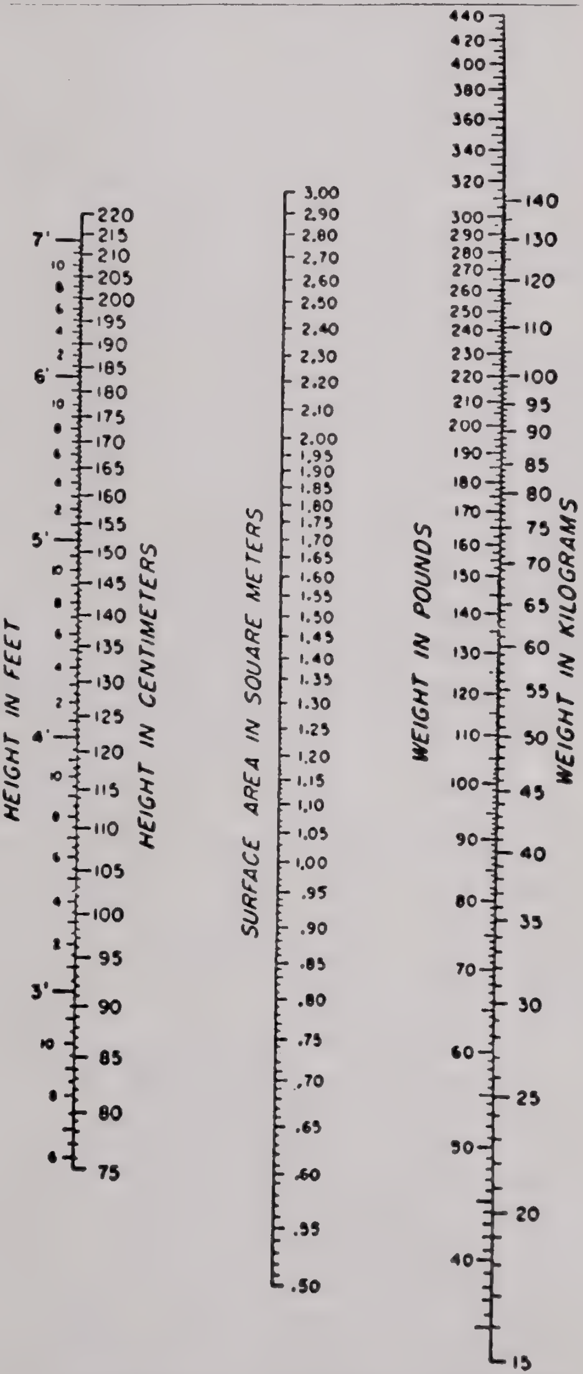
Children 6 to 12 — 1 tablespoon two or three times daily. (Note: Children weighing over 100 lbs. may require adult doses.)

Adults — 1 to 2 tablespoons two or three times daily.

Using body surface area as dosage gauge:
30 ml./M^2/24 hrs., divided into 2 or 3 doses.

Next, let us consider the application of surface area as a dosage gauge for solid

TABLE 4



Body Surface Area Nomogram for Older Children and Adults

To determine the surface area of the patient draw a straight line between the point representing his height on the left vertical scale to the point representing his weight on the right vertical scale. The point at which this line intersects the middle vertical scale represents the patient's surface area in square meters.

products:

TRIDIONE®

Using age as dosage gauge:

Infants:	300 mg.
Age 2 yrs.:	600 mg.
Age 6 yrs.:	900 mg.
Age 13 yrs.:	1.2 Gm.

Using body surface area as dosage gauge:
1 Gm./M²/24 hrs.

Piperazine Citrate

Using weight as dosage gauge:
250 mg. up to 15 lbs.
500 mg. 15-30 lbs.
1 Gm. 30-60 lbs.
2 Gm. over 60 lbs.

Using body surface area as dosage gauge:
1 Gm./M²/24 hrs.

Obviously, the relationship between dosage and body surface area is a constant in the case of most drugs. Use of this gauge would be simplified if liquid pediatric pharmaceuticals or a group of liquid pediatric pharmaceuticals were so formulated that a single dose of 10 ml. would be appropriate for a child with a surface area of 1 M².

Although solid products are less frequently used in pediatrics, particularly for infants and young children, they too can be dosed by use of surface area. For example, if a product were formulated so that the dose was 1 Gm./M²/24 hrs., a child with a surface area of 1 M² would be given 250 mg. four times a day; a child with a surface area of 0.5 M² would require 125 mg. four times a day, and so on. Obviously, small sizes of tablets would have to be available for dosage to be flexible.

Table 1 is an Equivalent Sheet showing *weight in pounds, sitting height in centimeters* (crown-rump length), *body surface area in square meters,* and *dose of liquid pediatric pharmaceuticals as above stipulated in milliliters.* Values for weights and surface areas are taken from *New Drugs,* 1966 edition.[28]

To simplify the presentation of dose information for the physician, the instructions need include only body weight along with the corresponding dose of liquids or solids. Table 2 shows how figures derived from the Equivalent Sheet could be used to give dose instructions for an imaginary product REX. In addition, a calculator or height-weight nomogram should be supplied for estimating surface area for children with unusual body configurations. Table 3 and Table 4 are DuBois nomograms.[17] Liquid products should be measured by use of a measure calibrated in milliliters and fractions of milliliters.

Comment

Use of body surface area as a gauge for dosage offers the advantages of simplicity, accuracy, and hence efficacy and safety. Obviously, the more potent the drug, the greater the need for precise dosage, the more useful is body surface area as a gauge.

Worthy of emphasis is the fact that use of body surface area as a dosage gauge does not involve a principle inherently different from that employed in using body weight. Rather, the use of body surface area represents a rational convenience. One can cite several advantages for surface area:

1. It makes it far easier for the physician to remember doses.

2. It is particularly useful in the case of drugs that are not used frequently.

3. The very simplicity of the gauge helps avoid error.

4. Once a patient's surface area is determined by whatever method, it can be used for various drugs, water, and electrolytes throughout the course of treatment.

At first glance, use of body surface area for dosing drugs appears to be a bold innovation. So did the use of the milliequivalent in place of the milligram, the metric system rather than the apothecary system, and the decimal monetary system as against the complex English pence-pound method. In science, progress is inevitable; many signs indicate that the use of body surface area as a gauge for dosage represents "the shape of things to come."

For most people the hardest thing about life is the living.

Surgical Treatment of Dizziness*

JACK L. PULEC, M.D.**
Rochester, Minnesota

DIZZINESS IS a frequent complaint of patients seen by both the specialist and the general practitioner. Although most patients with this symptom will have a benign form of vertigo, every patient requires a thorough evaluation in order that more serious disease, such as an acoustic neuroma, may be ruled out. A small but increasing number of patients with dizziness can benefit from surgical treatment. The development and careful execution of new procedures that do not merely destroy the end organ of hearing and balance but can selectively section the vestibular branches of the acoustic nerve are possible with the operating microscope. Since the hydrops of Meniere's disease can often be relieved by shunt operations, with preservation of both the hearing and balance function of the ear, it is now desirable to treat Meniere's disease surgically in its earlier stages.

When end organ disease, excluding tumors, has been definitely diagnosed, surgical treatment of vertigo should be employed only after a reasonable trial of medical treatment has been unsuccessful. Each pathologic situation as well as the stage and severity of disease and the general condition of the patient must be carefully considered, and the surgical procedure should be selected that would best fulfill the desired result.

Conditions that produce dizziness and are amenable to surgical treatment are generally those involving the acoustic nerve or vestibular labyrinth. These conditions are Meniere's disease; vestibular neuronitis; labyrinthitis secondary to surgery, infection, or the scarring of chronic middle-ear disease; tumors of the middle ear and mastoid, and acoustic neuroma. Occasionally, trauma to the labyrinth such as the basilar skull fracture involving the semicircular canals is best treated surgically. Sometimes an ear will sustain a partial injury from a viral infection such as measles or mumps or from a vascular accident that produces persistent dizziness.

**Mayo Clinic and Mayo Foundation: Section of Otolaryngology and Rhinology.

Four types of surgical procedures can be employed: (1) endolymphatic subarachnoid shunt, (2) otic-periotic shunt, (3) middle fossa vestibular nerve section, and (4) destructive labyrinthectomy.

Endolymphatic Subarachnoid Shunt

Since the symptoms of Meniere's disease are caused by the increase in the endolymphatic pressure, resulting in distention of the membranes of the inner ear and stimulation of the nerve endings with ultimate deterioration of these nerve endings, this dilatation may be prevented with shunting operations. Unfortunately, it is very difficult to enter the inner ear without destroying its function. For this reason, my colleagues and I have used the endolymphatic subarachnoid shunt operation most frequently. This operation avoids the inner ear by the production of an opening through the endolymphatic sac into the subarachnoid space which is entirely posterior to the otic capsule and, although it communicates with the inner ear, the endolymphatic sac is at such a distance that a risk of a hearing loss becomes very small. Requiring approximately 1½ hours, this procedure is done with the patient under general anesthesia. The endolymphatic sac is approached through an exposure similar to that of a simple mastoidectomy; the surgeon is careful not to injure the semicircular canals. A silicon rubber shunt tube approximately ¾ inch long is placed through both sides of this sac so that one end extends into the cerebellopontine angle and is freely opened to cerebrospinal fluid (Figure 1). The other end is placed within the sac so that a continuous flow of fluid is possible from the endolymphatic sac into the subarachnoid space. The patient's usual hospital stay is six days. This procedure is successful in approximately half of the patients in relieving all of the nonpermanent symptoms of Meniere's disease. The endolymphatic sub-

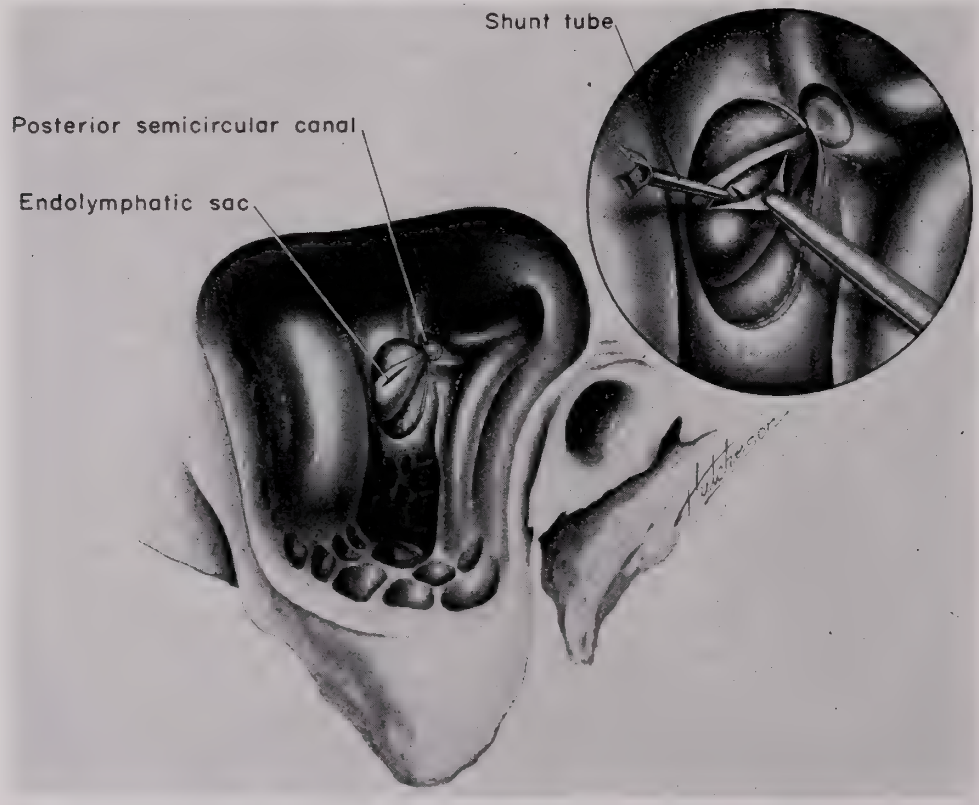

Fig. 1 — Endolymphatic subarachnoid shunt. Tube provides an opening from endolymphatic sac to cerebellopontine angle cystern.

arachnoid shunt procedure is best done when the surgeon does not wish to run any risk of making the patient's symptoms worse and when he wishes to prevent any further hearing loss or to improve the hearing situation. This procedure (1) relieves nonpermanent symptoms of Meniere's disease* in 50% of patients; (2) does not destroy the labyrinth; (3) acts to reduce all symptoms, such as fluctuating hearing loss, poor discrimination, tinnitus, pressure, and vertigo; and (4) works best when hearing is better than 50 db and fluctuates.

Otic-Perotic Shunt

Another method of producing a shunt between the endolymphatic and the perilymphatic systems can be accomplished through a standard tympanomeatal flap with the patient under local anesthesia and by an approach to the inner ear through the round window. This procedure has been called an otic-periotic shunt. Unfortunately, however, approximately 20% of patients will lose the function of the ear after this operation. Therefore, its use is reserved for patients who have very poor hearing or in whom the endolymphatic subarachnoid shunt has failed. The otic-periotic shunt has the advantage of the use of a local anesthetic and of minimal morbidity to the patient during and after surgery. Usually the patient is able to leave the hospital on the first postoperative day and has only some mild unsteadiness for about two weeks. This procedure is 90% successful in relieving the symptoms of Meniere's disease. The tiny platinum shunt tube that is pointed on one end is forced through the round-window membrane and blindly through the basilar membrane so that the shunt tube ultimately lies within the basilar membrane and allows a free flow of fluid between the scala media and the scala tympani (Figure 2). The round-window membrane rapidly heals over so that the inner ear is again sealed.

Middle Fossa Vestibular Nerve Section

Some conditions of the ear that produce vertigo involve only the vestibular portion of the inner ear so that a patient may have constant unsteadiness or recurrent episodic** vertigo but essentially no involvement of his hearing. Such conditions, when no obvious disease can be found except for dizziness and the objective caloric loss of the vestibular function of one ear, are called vestibular neuronitis. The pathology in this condition has never been clearly shown. However, it is a benign involvement of the vestibular portion of the ear. Another such situation can arise when a portion of the labyrinth is fractured. Occasionally with a basilar skull fracture or head injury the superior semicircular canal is cracked. Almost invariably, this condition cannot be detected

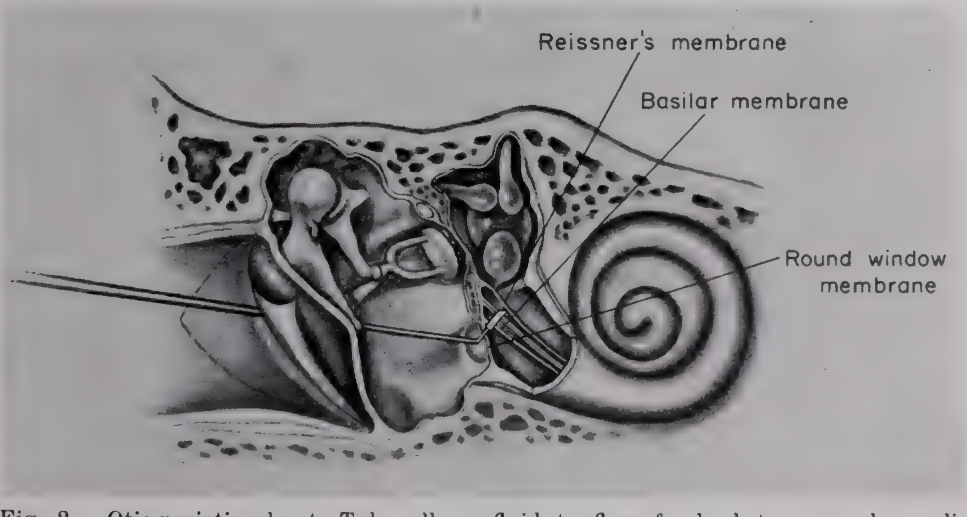

Fig. 2 — Otic-periotic shunt. Tube allows fluid to flow freely between scala media and scala tympani.

---

*See Editorial page 1563.
**See Test Your Word Score, Page 1573.

by means of a roentgenogram. One can usually detect or suspect such a situation when there has been some tinnitus or slight caloric involvement or a very mild hearing loss of one ear in a patient who has had an injury associated with subsequent persistent vertigo. In most patients with fracture, the vertigo will cease spontaneously within a few months. In a few, however, the vertigo persists and is best treated surgically. Still another condition is one in which there has been long-standing chronic otitis media which, in effect, produces a very mild circumscribed labyrinthitis and irritation of the vestibular labyrinth. In this condition the hearing can be somewhat impaired. However, it would be desirable in such a case, especially when the involvement is bilateral, to preserve what hearing function there is. For these conditions, namely those basically involving only the vestibular system, the selective sectioning of the vestibular nerve through the middle cranial fossa is the treatment of choice (Figure 3). In this method with the patient under general anesthesia, an incision similar to that for the treatment of tic doloroux is made above the ear. A 1¼-inch square of bone is removed from the squamous portion of the temporal bone, and the dura of the temporal lobe is elevated with a self-retaining retractor. The greater superficial petrosal nerve is identified, and the bone covering is removed with a diamond drill. This nerve is traced to the geniculate ganglion, and the facial nerve is followed to the internal auditory canal. A small portion of bone is removed from the superior portion of the internal auditory ca-

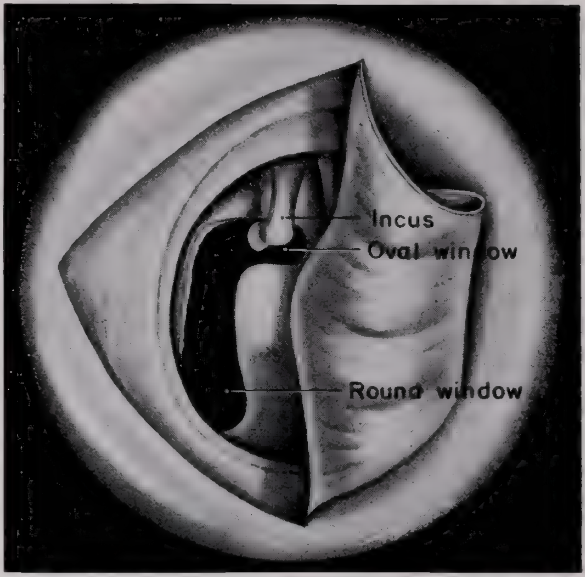

Fig. 4 — Transcanal labyrinthectomy with bone removed between windows.

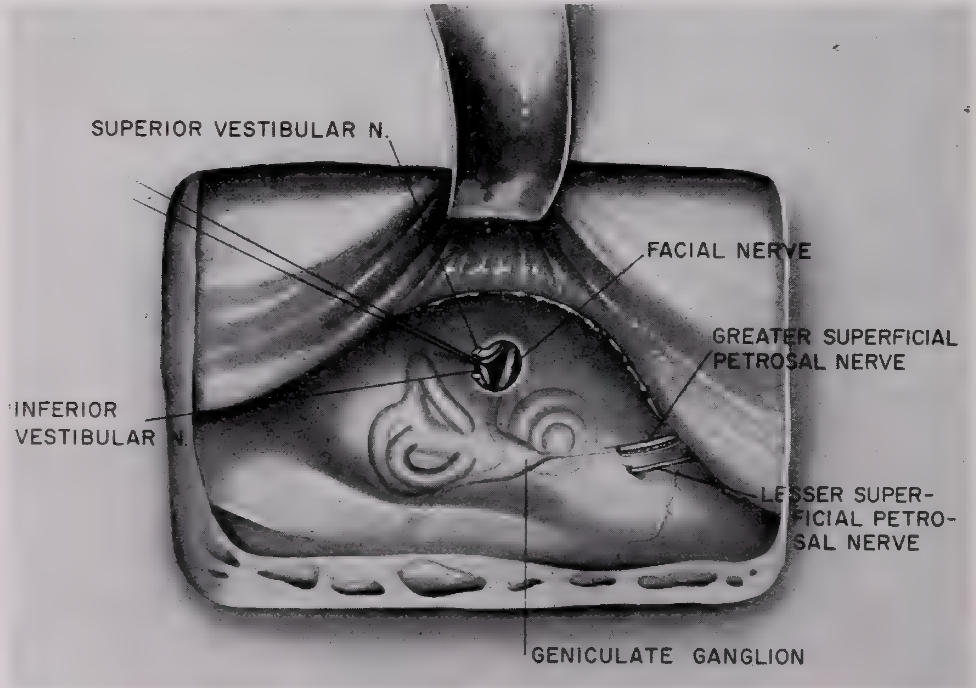

Fig. 3 — Middle fossa vestibular nerve section.

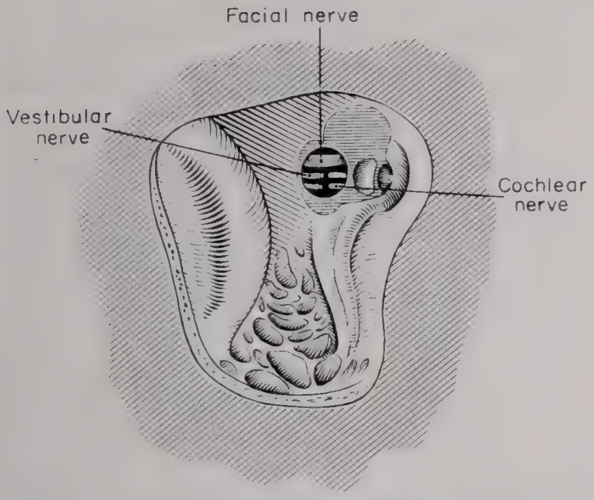

Fig. 6 — Translabyrinthine section of the eighth nerve.

nal so that both the facial nerve and the superior vestibular nerve are clearly identified. When this has been done, a hook is placed around the superior vestibular nerve and also around the inferior nerve, and these nerves are sectioned. The hospital stay for this procedure is six days, and the patient usually makes a full recovery within four to six weeks. The hearing is left unchanged.

Destructive Labyrinthectomy

Another type of surgical treatment is one that produces a destructive labyrinthectomy. This end can be accomplished in three different ways, depending on the desired results. One way is through the transcanal approach similar to a stapedectomy in which the stapes is removed and the membranous structures of the inner ear are removed with hooks and suction (Figure 4). This procedure requires a local anesthetic and is successful in removing all vestibular and cochlear function in approximately 85% of patients. Hospital stay is three or four days or until the patient is steady enough to leave. The second method is one in which more thorough labyrinthectomy can be accomplished through a postauricular incision (Figure 5). This procedure is done with the patient under general anesthesia. The bone of the mastoid is removed and the semicircular canals and posterior half of the vestibule are removed, along with the nerves to the canals. This procedure is very effective in removing all of the balance portion of the ear and is used in patients in whom

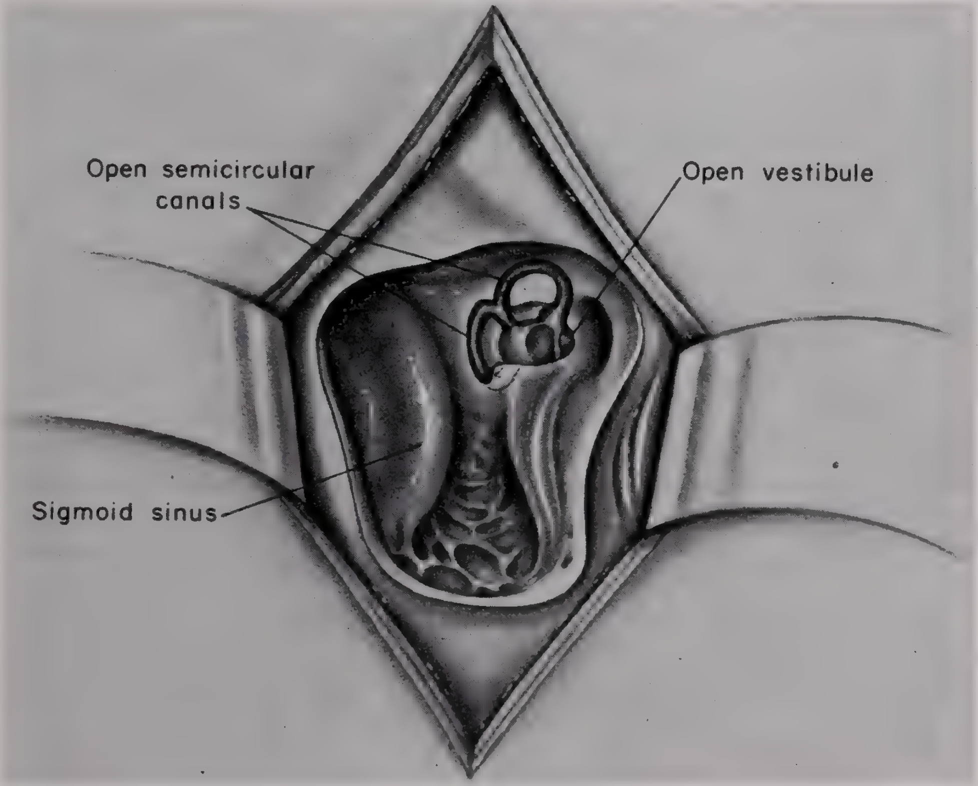

Fig. 5 — Postauricular labyrinthectomy.

scarring in the labyrinth is suspected or a previous unsuccessful procedure such as transcanal labyrinthectomy has been performed. Occasionally in a patient on whom a destructive labyrinthectomy is necessary but who complains a great deal of tinnitus along with dizziness, a translabyrinthine section of the eighth nerve is done (Figure 6). This procedure also is done with the patient under general anesthesia and is similar to a postauricular labyrinthectomy with the exception that instead of stopping the surgery after the semicircular canals have been removed, a little more bone is removed until the internal auditory canal has been exposed and the facial nerve clearly identified. A hook is then placed around the cochlear nerve, and the nerve is sectioned. If an acoustic neuroma is present, it can be safely removed, with preservation of the facial nerve. Although this method does not ensure a 100% cure of the patient's tinnitus, it is my impression from experience during the past two years that this operation offers a higher percentage of relief from noise in the head when the noise definitely results from an abnormal condition of the ear.

Summary

Surgical treatment of dizziness can be accomplished by a number of operations that selectively attack specific areas of the ear or try to accomplish certain definite change on the ear. These are: endolymphatic subarachnoid shunt, otic-periotic shunt, middle fossa vestibular nerve section, and destructive labyrinthectomy (transcanal, postauricular, or translabyrinthine section of the eighth nerve). Once a careful diagnosis has been made, the treatment must be adapted to each individual patient's need. No absolute criteria can be used for every patient who has benign disease. However, when an acoustic neuroma has been detected, it should be removed. With the judicious employment of the surgical procedures, physicians will less frequently find themselves having to tell the patient that nothing can be done for his dizziness and that he must learn to live with it.

ANGIECTID SYNDROME

This term has been used to describe a type of superficial venous lesion which appears during the first trimester of pregnancy. These vascular abnormalities occur on the posterior thigh and calf areas and consist of small, intradermal, raised, sharply circumscribed clumps of blood vessels. The areas are tender, have increased local temperature, and may be painful. They are reported to be present in approximately 10 percent of all obstetric clinic patients and are not related in any way to thrombophlebitis or to the commonplace saphenous varicosities of pregnancy.

According to Fried and associates, a distinct etiologic relationship exists between these lesions and the level of female sex hormones, more particularly with variations in the titers of serum estrogen and urinary pregnanediol. Patients with the most painful lesions show the greatest degree of estrogen or pregnanediol lack. After being present for a few weeks the lesions sometimes disappear spontaneously, but usually continue longer, often throughout the period of pregnancy and for a few weeks postpartum. Treatment consists preferably of estrogen administration in doses of 50 to 150 mg. daily. Relief of pain is usually prompt. It has been recommended that therapy be continued until the expected date of delivery.

Dermoids of the Head and Neck

BRUCE W. TAYLOR, M.D.*
JOHN B. ERICH, M.D.**
MALCOLM B. DOCKERTY, M.D.†
Rochester, Minnesota

TUMORS OF CONGENITAL origin are not infrequent entities that present problems in diagnosis and treatment. Although potential for their development is present in early embryonic life, their presence may not be apparent until long after birth.[1] Because of their insidious development they are occasionally confused with other tumors. Since these tumors may arise in obscure locations, they may become significant problems in treatment.

Some of these congenital tumors exhibit differentiation of tissues indicative of an origin from all three germinal layers, and in certain locations, notably the testis, the resulting histologic "potpourri"‡ is practically always malignant — teratocarcinoma or malignant teratoma. In the ovary, by contrast, although all three germinal layers are represented, emphasis is developed along ectodermal lines, with the resultant dermoid cyst almost always containing a large hairball and the growths being benign in 99% of cases. Mediastinal and pineal tumors of comparable type exhibit intermediate degrees of tissue complexity and incidences of malignant transformation.

Other areas of the body bear their quota of tumors which have in common a grossly cystic architecture and a lining of squamous epithelium with or without specialized adnexal structures, such as hair follicles, sweat glands, or sebaceous glands. The greatest percentage of these tend to concentrate in midline areas or in other zones wherein embryologic fusion-lines occur. Smooth-muscle strands in the walls of these cysts indicate mesodermal participation but, unlike the situation with their counterparts in the gonads, entodermal elements are almost invariably absent.

The pathogenesis of these congenital growths is a matter of controversy. Willis[2] noted that "dermoids" predominate in dorsomesial positions (spinal cord, sacral area) and about the face at the inner and outer angles of the orbit, external angular process of the frontal bone, nasofrontal sulcus, and on the cheek behind the angle of the mouth. He postulated that the tumors in these locations arose from sequestered epithelial remnants. Other authors[1,3,4] have favored an origin based on ectodermal displacement by ingrowing membranous bone. Cysts of dental origin[5] form from proliferation of paradental epithelial debris, which is "normally" present in the gums and which fails to undergo anticipated dissolution.

In many of these locations, cysts resembling dermoids microscopically but lacking a content of hair can be "acquired" by such diverse means as traumatically implanting a bit of squamous epithelium or obstructing the duct of a sebaceous gland. In these last two categories the designation "epidermoid cyst" is usually applied.

Thus it is fairly obvious that difficulties arise not only over the pathogenesis of dermoids but also over what to include in the dermoid category. For the purpose of this paper, a dermoid cyst is defined as one lined by squamous epithelium along with hair, hair follicles, sweat glands, or sebaceous glands, either alone or in combination.

Material

The cases involving dermoids seen at the Mayo Clinic during a 25-year period from 1936 to 1961 were reviewed. Dermoids involving the head and neck were the main concern; but for comparative statistical purposes those listed as occurring elsewhere in the body were studied in lesser detail. A total of 780 cases were originally screened.

In 206 cases no operation had been per-

formed. These were immediately deleted from the survey since the clinical diagnosis could not be confirmed. In an additional 33 cases the tumors did not qualify for inclusion in the dermoid category as herein defined. Of the remaining 541 cases, those involving lesions of the head and neck were segregated for detailed study, while those in other areas were merely classified as to location. Dermoids of the head and neck accounted for 183 of the total.

Series of 183 Dermoids of the Head and Neck

Incidence and Distribution

Dermoids of the head and neck represented the largest group and constituted 33.9% of the total. The abdomen, pelvis, brain, spinal cord, chest and mediastinum constituted the balance,* as indicated in Table 1. The head and neck dermoids were distributed as detailed in Table 2. In lateralized lesions, there was a slight preponderance (70 to 57) or right-sided involvement.

Slightly more than 30% of the lesions were noted at birth, and 50% were noted before the patient had reached the age of six years (Table 3). Almost all of the tumors involving the brow were noticeable at birth.

The average age of all patients at the time of operation was 19.8 years (Table 4). The youngest patient undergoing surgery was six weeks old and the oldest 78 years of age. In both of these patients large dermoids that interfered with swallowing were present in the floor of the mouth. The younger patient also had a cleft lip.

The average age at operation varied according to the location of the lesion. In the youngest group (average age 12 years) the tumor was in the nasal region and in the

oldest (average age 32 years) in the lip and nasolabial area. About one quarter of all patients (25.1%) were seen after the age of 30 years, but only 17 (9.3%) had not noted the lesion by this time.

Sex Distribution

Sex distribution was likewise fairly even throughout the various areas involved by dermoids. Slightly more males than females had dermoids in the brow, mouth, nose, skull, and neck area, whereas more females had dermoids in the eye and auricular area (Table 5).

History and Clinical Observations

Sinus Drainage

A discharging sinus at one time or another was present in 17 cases (9.3%), and in six cases this was the initial symptom. Discharging sinuses were present in seven of the 14 cases of nasal dermoids; all dermoids were in the midline, and, at operation, all were found to run deeply under the nasal bones.

There were five patients who were unaware of the tumor, and it was discovered only on clinical examination or during another operation.

Infection

Acute infection in the region was the initial symptom in two cases, and pain was the only difficulty noticed in one case. Recurrent bouts of acute infection were noted in five cases. In seven cases there was a history of trauma some time before the onset of swelling or discharge; in five of these the trauma occurred in connection with a nasal dermoid.

Other Clinical Manifestations

The initial difficulty was exophthalmos in two of the cases of orbital dermoids and ptosis in another. One patient sought relief from "tongue burning" and another from "eye burning."

In one notable case, that of a 58-year-old woman whose occipital dermoid had been present since birth, the patient had no complaints and sought treatment only when her lesion had reached 18 cm. in diameter.

Some form of discomfort was present in 15 cases, varying from a "sense of pressure," a "dull ache," "occasional tenderness" to "shooting pains."

Seven patients claimed that the tumor fluctuated in size. Of the patients with sublingual dermoids, two noted difficulty in swallowing, two complained of inability to swallow properly, and one, a 59-year-old man, had such difficulty in breathing that tracheotomy was necessary to save his life.

In only four of the patients undergoing dermoid removal could a family history of any congenital abnormality be obtained. Two of these patients each had a sibling with a dermoid in the same location (brow) as they did. One patient with a pre-auricular dermoid had a sister who had undergone surgery for a branchial cyst and sinus. The mother of one patient with a brow lesion had a congenitally deformed ear.

Other congenital abnormalities were observed in 16 patients (8.7%), in six of whom multiple additional defects were noted.

In no cases was any malignant lesion reported from the site of the dermoid; however, one patient, a 39-year-old man who had had a large dermoid of his brow removed, also had a basal cell epithelioma of the root of his nose removed at the same time.

In one 59-year-old man, an epithelioma of the lower lip was removed two years after operation for a large dermoid, 5½ cm. in diameter, in the floor of the mouth. Ten years later he died of gastric carcinoma.

Pathologic Features

The dermoids varied in size from several millimeters to more than 17 cm.; the average size was 1 to 2 cm. Those in the floor of the mouth and midline of the neck averaged about 4 cm. in diameter and those on the eye, about 0.5 cm. The wall of the cyst was thick and fibrous in many cases, although occasionally a very thin wall was noted. The contents of the cyst varied from straw-colored liquid to thick, white "cheesy" material. In many cases yellow or brownish oily or pus-like material was present.

On gross examination strands of hair were noted in 43 (23.5%) of the 183 dermoids, the hair content varying according to location.

Those dermoids on the brow and scalp commonly contained hair, while there was none in the lesions on the eye.

On microscopic examination, inflammatory cells were seen in many of the dermoids. Squamous epithelium, sebaceous glands, sweat glands, hair follicles, and smooth muscle were commonly noted. In only one specimen were apocrine glands* seen. No evidence of cartilage, bone, or lymphoid tissue was noted, and entodermal elements were likewise conspicuous by their absence.

Therapy

Of all 183 patients undergoing surgical removal of the tumor at the Mayo Clinic, 40 had had an initial operation at another institution.

Surgery

Initial therapy usually consisted of incision and drainage (19 cases). In some instances this had been repeated several times; in one patient with a dermoid below the left ear no less than eight separate drainages had been performed. In one case two operations were required to completely remove a large tumor (6 cm. in diameter) in the floor of the mouth.

Needling

Other therapy included "needling" or needle aspiration, injection with sclerosing solution, and injection with antibiotics; and, in one case of a four-month-old child, a course of radiation therapy had been undertaken to cure what was thought to be a hemangioma.

Other Procedures

Secondary procedures were required in four cases: in one case, to insert an acrylic plate where a large bone defect had resulted from removal of a brow lesion; in another, to excise an "amputation-type neuroma"; and, in two cases of nasal dermoids, to use a cartilage graft to build up a defect of the nasal bridge. On four occasions nerve deficiencies were noted after operation.

Surgical Sequellae

Two patients have diplopia; one has ptosis from orbital dermoids, and another has poor visual acuity in one eye "due to retinal artery occlusion at the time of difficult surgery."

Temporary muscle weakness was noted in the orbital region in one case, and hypoglossal nerve trauma caused a tongue deviation in another.

Discussion

Various reports have placed the incidence of dermoid of the head and neck at a very low figure.[6,7] In this study it was 33.9%. One basic reason for this difference may be that, in several series, there was the inclusion of a large number of cases of dermoids from regions of the body that have been found to contain few dermoids (as they are defined in the present study).

The figure of postanal dermoids in New and Erich's[7] work was 44.48% of the total, whereas in the present study only 5.2% were found in this location.

If the ovarian and sacral dermoids are eliminated from these two series[6,7] and from the present one, the results become more compatible. The head and neck then are the predominant sites of dermoids of the body in all three series.

The number of dermoids noticed at birth varied in different sites of the body. In the neck and floor of the mouth, the number noted is not nearly so great (seven of 41 cases); most of these lesions were first noted in the second and third decade.

Perhaps this is the reason that most of the dermoids in the neck and floor of the mouth are larger than those at other sites, since they go unnoticed longer and can easily expand in the relatively soft surrounding tissue. In contrast, those about the eyes are more often noticed at birth (38 of 74 cases recorded in this study) or soon after, and are usually rather small when removed.

The length of time after the lesion was noticed and before treatment was sought seems extreme in many instances. It appears that most of the patients with small lesions are children who are brought for examination by their parents. But for most adults the time interval is much greater and cosmetic effect, fear of cancer, or discomfort of some sort is the usual reason for requesting treatment. The average age at operation for patients in this series was 19.8 years.

---

*See Test Your Word Score, Page 1573.

Other congenital deformities were found in 16 of the 183 patients in this series (8.7%). These deformities varied from multiple congenital ones in five cases and a cleft lip and palate in one case to defects of a more minor nature in 10 cases. These 10 cases included two patients with hemangiomas, two with pilonidal sinuses, two with auricular deformities, one patient with a nasal defect, one with a cleft of the soft palate, one with an undescended testicle, and one with a dorsal sinus of the penis.

In Crawford and Webster's[6] series of 14 patients with nasal dermoids, two had other minor deformities. Also in the present series of 14 patients with nasal dermoids, two had minor deformities; one patient had multiple deformities of the face, urogenital system, spinal column, and extremities, and the other had a cleft lip and palate. In the series of New and Erich[7] one patient with a nasal dermoid of the septum had clefts of the upper lip, columella, and nasal tip; and Weisman and Johnson[8] reported a bilateral cleft lip and palate in which an unsuspected nasal dermoid was encountered at surgery.

The present series revealed only four cases in which congenital deformities were also present in other members of the family. In two cases of dermoids of the brow, a similar finding had been present in a sibling; the mother of a child with a large dermoid of the brow had congenital deafness in the ear on the same side as the child's defect and, in another patient with a dermoid in the left preauricular region, a sister had had a branchial sinus and cyst removed some years earlier.

In 1937 New and Erich[7] reported a mother and daughter who had identical nasal dermoids, and also a father and a son with preauricular sinuses.

Stupka[9] reported a father and daughter with similar nasal dermoids and, in 1938, Furniss[10] presented the cases of twin boys, each of whom had midline nasal dermoids.

Dermoids of the eye appear to be commonly associated with multiple congenital defects (three of five cases in this series).

The only malignancy found in this study in the same general region as the dermoids was a small basal-cell epithelioma of the nose in a 39-year-old man with a dermoid of the brow that was 2.5 cm. in diameter. The age of the patient and the site and type of cancer would lead one to believe that there was no association in the lesions. New and Erich[7] reported a squamous-cell (grade 2) epithelioma of the palate associated with a dermoid; however, in this location, chronic irritation may have been a factor and previous surgery and scarring had occurred. Many authors[7,11-13] have stated that dermoids can undergo malignant degeneration and may metastasize to lymph nodes; from this study and a review of previous cases this seems most unlikely.

Recurrence in our experience is related not to any malignant potential but to incomplete removal of the lining of the cyst. However, dermoids have been found to cause local destruction purely by their expanding properties per se.

Conclusions

A high incidence (33.9% of all dermoids of the body) was found in the head and neck. The inclusion of many ovarian and sacral lesions in other series perhaps accounted for the previously reported low figures.

All of the lesions were found to be in sites of embryonic fusion. Lesions in the most noticeable regions of the body were removed at an earlier age and were of smaller size.

The high recurrence rate is most likely due to difficulty in diagnosis of the dermoid and subsequent inadequate removal for complete cure. The difficulties in recognition of this lesion and the frequency of surgical difficulties produced by its deep extension, especially in the nasal and occipital regions, indicate a need for greater awareness of this condition.

None of the tumors in the present series exhibited a malignant potential.

Reevaluation of Ileostomy Appliances and Their Application to Pediatric Patients*

HAL E. HOUSTON, M.D.**
HUGH B. LYNN, M.D.†
Rochester, Minnesota

IT HAS BEEN only within the last few years that a more aggressive surgical approach has been taken toward chronic ulcerative colitis and other diseases of the colon requiring a total colectomy and permanent ileostomy in children.

Several factors are responsible for this new outlook. The most important is a realization on the part of the physician that the earlier the irreparably diseased colon is removed, the better these children do in growth and social adjustment. The improvements in pediatric anesthesia and in preoperative and postoperative care have contributed greatly.

The major contribution to postoperative care has been the evolution of a "better mouse trap," so to speak, in the form of a better appliance. There are many commercially available appliances. Practically all depend on some type of adhesive to hold the appliance in place. Many are also bulky, odorous, and leaky (causing skin irritations), and they are quite complicated to assemble, particularly for a child. The magnitude of ileostomy problems was studied by McNamara and Farber,[1] who sent questionnaires to 1,048 patients including children and adults. Seventy-nine per cent had some sort of circumileostomy difficulty, mostly due to ill-fitting appliances and use of adhesives.

Because of the many drawbacks and problems, we searched around for a more suitable appliance. We are now using the Robinson ileostomy appliance at the Mayo Clinic.

Construction of Appliance

This is an extremely simple device, designed by the late Mr. Herman Robinson of Seattle, Washington, around 1958.[2] Steven-

---

*Read at the meeting of the Southern Minnesota Medical Association, Minneapolis, Minnesota, September 10, 1965.

**Mayo Graduate School of Medicine (University of Minnesota), Rochester: Resident in Surgery.

†Mayo Clinic and Mayo Foundation: Section of Surgery.

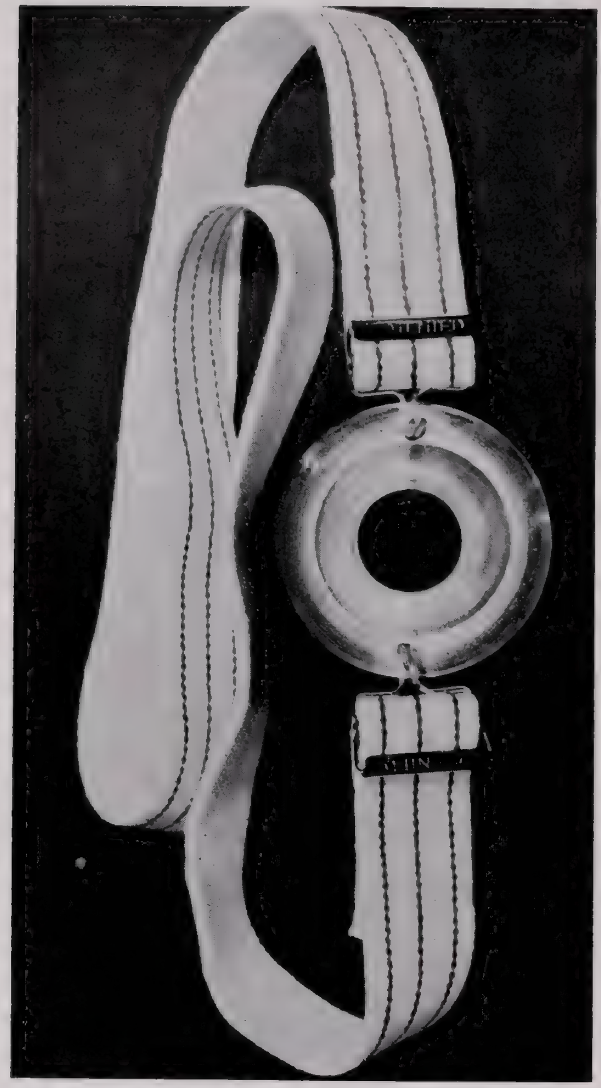

Fig. 1 — Appliance with belt attached.

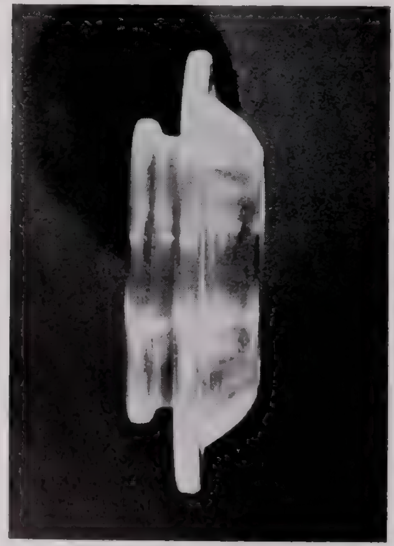

Fig. 2 — Lateral view of appliance.

son and Volwiler[3] at the University of Washington were the first to use the appliance on a large scale. This appliance consists of a plastic disk which is convex on the skin side. When the belt is attached, the convex surface presses against the skin surrounding the stoma and causes the stoma to protrude into the ring (Figures 1 and 2). This creates a seal which will not allow odors or liquids to escape. No adhesives are used. A Saran plastic bag is attached to the disk by turning the bag inside out, inserting the disk inside the bag, and applying a rubber band (Figure 3). An opening is made in the bag by use of a fingernail file or small scissors (Figure 4). The bag is then turned right-side out and a rubber band is applied to the distal part. It is now ready for wear (Figure 5).

Stomal Location

The stomal location is of utmost importance in fitting an appliance. The surest way of putting the ileostomy in the proper place is to have the patient wear the appliance for a day or so preoperatively to decide exactly where it fits best. This also has some psychologic benefit in that he is deciding himself where the permanent location will be. Figure 6 shows one of our patients wearing the appliance preoperatively; he had suffered from severe chronic ulcerative colitis with secondary arthritis of the left knee. He previously had undergone a partial colectomy and ileoproctostomy. He returned because of ulcerative colitis involving his rectum. He later named his stoma "Cyclops" because, he said, it had just one eye.

The night before operation the skin is scratched in the center of the disk, and the stoma is located at that site at the time of surgery. Ideally, the stoma should be constructed so that it protrudes 2½ to 3 cm. above the abdominal wall. We prefer the Brooke-type ileostomy.

Postoperative

A Bongort plastic adhesive bag is applied at the time of surgery. Seven to ten days postoperatively, when the mucocutaneous areas appear healed and most of the stomal

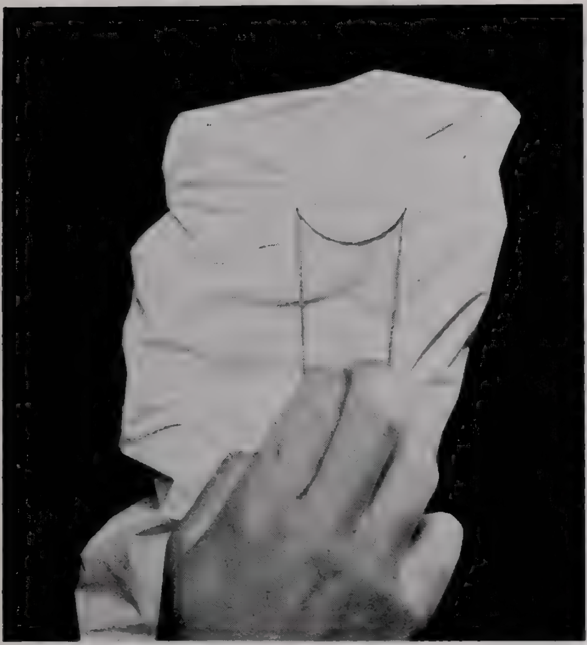

Fig. 3 — Attachment of bag to appliance.

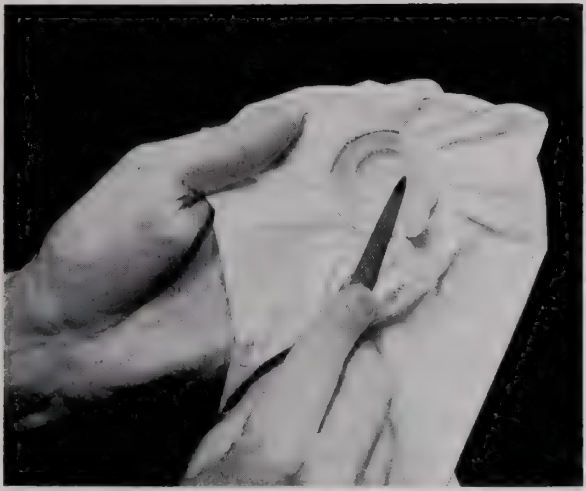

Fig. 4 — Creating opening in bag.

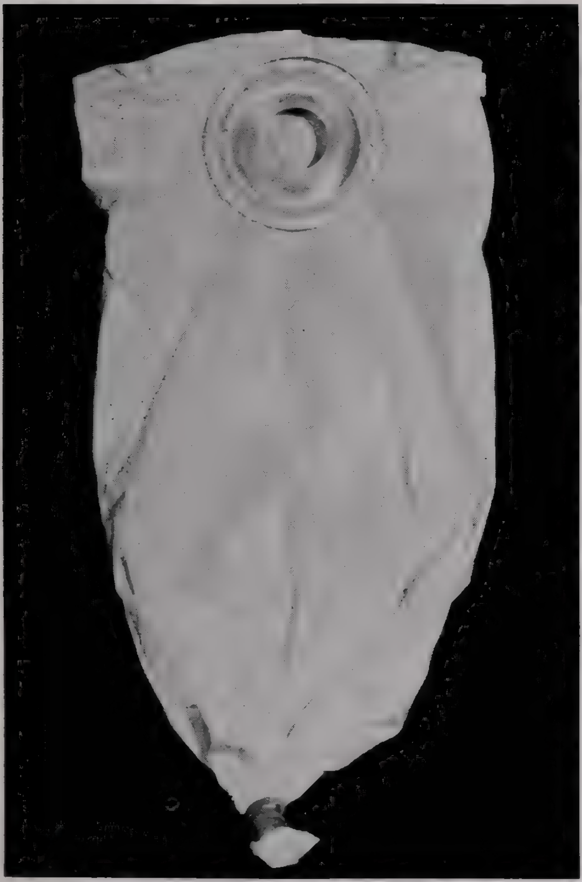

Fig. 5 — Appliance ready for wear.

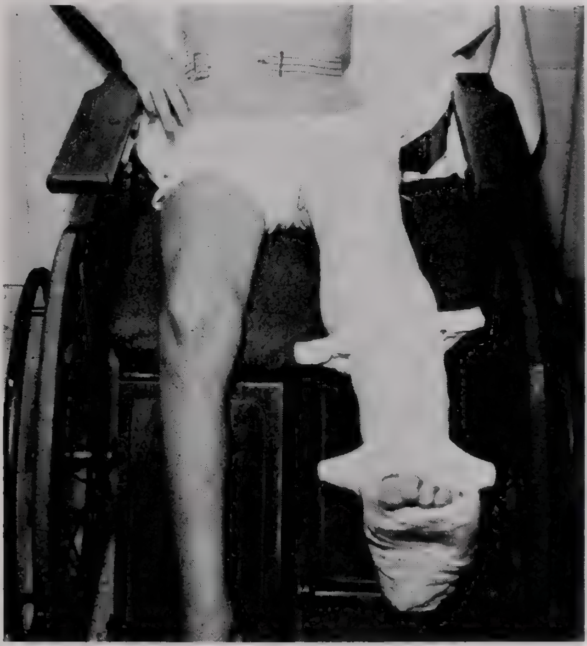

Fig. 6 — Preoperative fitting.

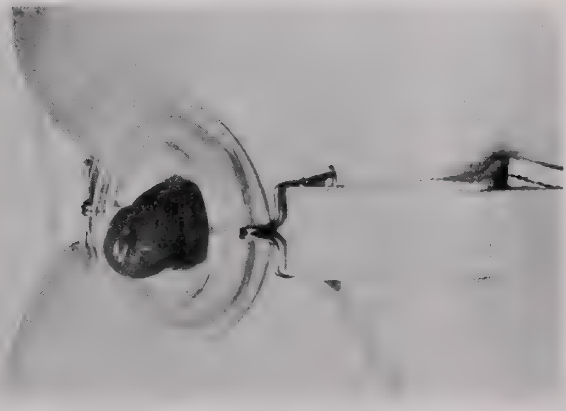

Fig. 7 — Appliance is fitted postoperatively.

edema has subsided, the diameter of the stoma is measured by use of a caliper. An appliance is then fitted that leaves approximately an eighth of an inch of skin exposed around the stoma (Figure 7). It may be necessary to convert to a smaller-size appliance at a later date if stomal shrinkage occurs.

Complications

To date we have used the Robinson ileostomy appliance in children ranging from 8 to 15 years of age. We have fitted several children who had their ileostomies performed elsewhere but because of ileostomy and appliance difficulties were seen at the Mayo Clinic. There have been no problems with leakage, odor, or skin breakdown. Because of its simplicity, practically all children are able to take care of their own appliances. Our only complication occurred in a boy who rubbed a raw area on the lower side of the stoma while playing football. At a later date, while playing basketball, he actually broke one of the eyelets to which the belt attaches. Many of our patients are active in various forms of athletics, including swimming.

Summary and Conclusions

Stomal location is extremely important in proper fitting of an ileostomy appliance and when possible should be decided on preoperatively.

The Robinson ileostomy appliance has been used in children ranging from 8 to 15 years of age at the Mayo Clinic. There have been no problems with odor, leakage, or skin breakdown.

The pursuit of a normal childhood has been made possible, including participation in all types of athletics.

The ileostomy appliance is the problem and the responsibility of the surgeon. While any patient with an ileostomy soon learns more about its management than his surgeon knows, it is not fair for the surgeon to turn his back on these patients and expect ileostomy clubs, surgical supply houses, family, and neighbors to bear the full responsibility for having these patients adjust to their problems. Many patients will lead lives of misery because of poorly fitted appliances. The Robinson ileostomy appliance has made this situation much more tolerable, and it is our impression that youth itself is also a great aid in this period of stress.

IT'S THE LAW

The present position of the state welfare department demanding that the doctor accept assignment of benefits is a departmental directive and *not* a law. The welfare board is required by law to pay the medical expenses of their clients. The welfare board is the prime contractor for medical services to their recipients and is, therefore, directly responsible for their medical expenses. Any arrangement of the welfare board with a third party such as Medicare is their particular concern and not a concern of the medical profession. The contract is between the welfare board and Medicare, and the physician is not involved.

One Man's Meat

In some other countries, where conditions of living are entirely different from those in the United States, problems of health have been solved by socialization of medicine, but to assume that we should imitate those solutions is ridiculous.—Charles Mayo

Obstruction to Left Ventricular Outflow*

Functional and Clinical Considerations

JAMES N. KARNEGIS, M.D.**
YANG WANG, M.D.†
St. Paul, Minnesota

Obstruction to the flow of blood from the left ventricle can exist either below, at, or above the aortic valve. Thus there may be subaortic, valvular aortic, or supravalvular aortic stenosis. The purpose of the present paper is to correlate the functional and clinical manifestations of these three levels of obstruction with the basic mechanisms of each.

Basic Considerations

Subaortic, valvular aortic, and supravalvular aortic stenosis share in common the fundamental disturbance of an obstruction to the forward flow of blood, the obstruction requiring that the pressure be increased proximally to maintain flow. A pressure gradient can therefore be recorded as the catheter tip crosses the stenotic area. The relationship between the variables — blood flow, pressure gradient, and severity of stenosis can be seen from the statement that flow is proportional to orifice size and the square root of the pressure gradient.[1]

Similarities between the Various Types of Left Ventricular Outflow Obstruction

The left ventricle hypertrophies as a consequence of the increased work load imposed by the stenosis. With the exception at times of idiopathic hypertrophic subaortic stenosis, the hypertrophy is usually concentric, and in the absence of left ventricular failure the cardiac silhouette is generally not enlarged by roentgenography. For this reason hypertrophy can often be better appreciated from the electrocardiogram than from the roentgenogram. Marked left ventricular hypertrophy can produce electrocardiographic patterns resembling those seen in myocardial infarction; but these changes are perhaps more often seen in muscular subaortic stenosis where there is an extreme hypertrophy of the interventricular septum.

†Associate Professor, Department of Medicine, University of Minnesota Medical School, Minneapolis, Minnesota.

A similar symptomatology is seen in subaortic, valvular aortic, and supravalvular aortic stenosis. This includes dyspnea, angina, syncope and heart failure. The onset of any of these symptoms is of ominous import.

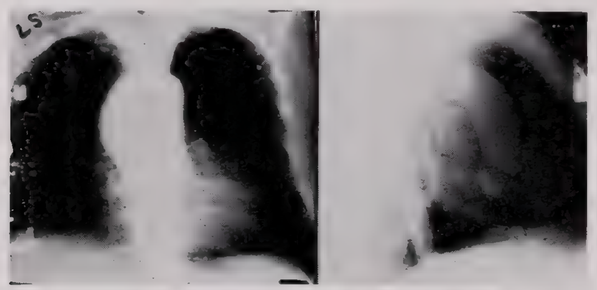

Fig. 1 — Retrograde supravalvular aortogram of a 53-year-old man with both severe calcific aortic valvular stenosis and severe coronary arterial disease. Left: posteroanterior view. Right: Lateral view. Note the negative jet of blood squirting through the stenotic valve during ventricular systole, and the post-stenotic dilatation of the aorta. The coronary arteries are also diseased.

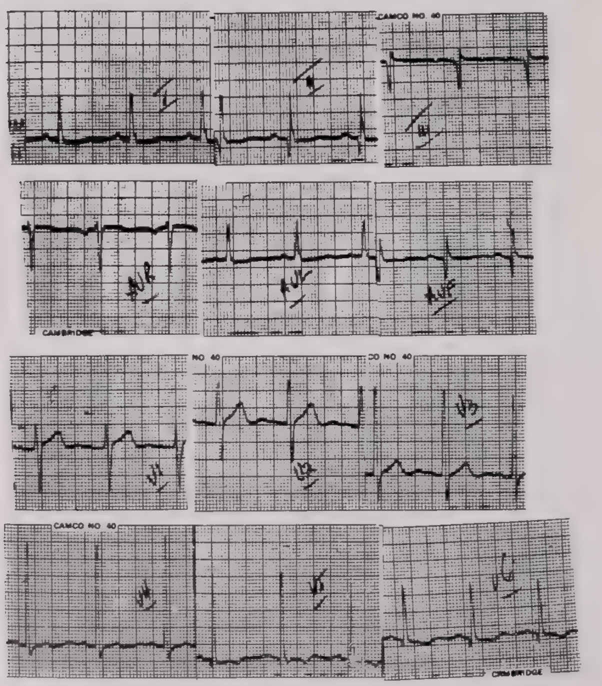

Fig. 2 — Electrocardiogram of the same patient as in Figure 1. The deep Q and abnormal T waves in Leads II, III, and aVF indicate an old posterior myocardial infarct. However, the tracing fails to show good evidence of the additional presence of severe aortic valvular stenosis.

Decompensation occurs when the left ventricle can no longer sustain its work load and is associated with a high left ventricular mean diastolic pressure. The pressure is also elevated in the left atrium and proximally. An elevation of pulmonary venous and capillary pressure above a critical value produces pulmonary edema. This sequence of events explains the symptoms of dyspnea and congestive failure.

At the same time that congestion occurs upstream to the obstruction, there is interference with the forward flow of blood. A reduction in the cardiac output and the diminished perfusion of the brain can result in faintness and syncope, events most likely appearing when the patient assumes the erect position, since the heart must then overcome the highest column of blood in order to nourish the brain. The combination of decreased cardiac output and increased left ventricular work, together with hypertrophy, accounts for the presence of angina pectoris.

The final condition that is shared by patients with these lesions is sudden death, a dread event that can occur even while the patient is asymptomatic.

Dissimilarities Between the Various Types of Left Ventricular Obstruction

Although subaortic, valvular aortic and supravalvular aortic stenosis share some findings as described above, there are also interesting differences. These dissimilarities occur because of the difference in the level of the obstruction, because of some special characteristic of the basic lesion, or because of different defects or conditions which occur in association with the basic lesion. These features can best be discussed by individually considering valvular, supravalvular and subvalvular aortic stenosis.

Valvular Aortic Stenosis

Valvular aortic stenosis is the most common form of left ventricular outflow obstruction.[2,3] The usual etiology is rheumatic fever, although congenital stenosis does occur. Aortic valvular stenosis is seen more frequently in men than in women.

Typically there is a coarse ejection murmur at the base which often radiates along the carotid arteries.[4] A systolic thrill may also be palpable. The aortic closure sound is usually diminished or absent, but is occasionally present even when the stenosis is severe. The second heart sound may be single; occasionally it may split paradoxically, in which case the aortic closure sound follows the pulmonic closure sound. This effect is probably due to the prolonged left ventricular ejection period produced by the stenosis. An ejection click may be heard especially at the base, and a fourth heart sound is sometimes audible at the apex. An aortic valve which is stenotic may also be incompetent.

Roentgenograms may show valvular calcification. Poststenotic dilatation occurs principally in the ascending aorta. Aortography may show a ragged border to the valve and a negative jet of blood squirting through the stenotic orifice (Figure 1).

The aortic pressure pulse usually shows a slow ascending limb which may have an anacrotic* notch. Typically the pulse pressure is small. Aortic stenosis is occasionally associated with systemic hypertension.

Severe aortic stenosis complicated by severe coronary arterial disease can be a difficult diagnostic problem. Angina pectoris, dyspnea, and heart failure can occur with either condition, and the electrocardiographic findings may not be clear-cut. The patient whose aortogram is shown in Figure 1 was such a case. He had severe angina, angiographic evidence of coronary arterial disease, and severe calcific aortic stenosis confirmed at surgery. His electrocardiogram (Figure 2) showed evidence of an old posterior myocardial infarct, but little that was suggestive of his valve lesion.

Supravalvular Aortic Stenosis

Supravalvular aortic stenosis can occur either alone or as part of a syndrome. The belief has been that the isolated lesion occurs more frequently, but recent proposals have suggested that more commonly it is part of a syndrome, the other features of which may not be clearly in evidence or may even be absent.[5]

The area of the stenosis can be visualized by angiocardiography. Figure 3 is an example of a patient with supravalvular aortic stenosis together with tubular aortic hypoplasia. A pressure gradient can be recorded as the catheter tip is withdrawn across the supravalvular stenotic area, as demonstrated in Figure 4. In contrast to aortic valvular stenosis where the coronary arteries arise downstream to the area of obstruction, in supravalvular aortic stenosis the ostia of the coronary arteries are proximal to the level of the obstruction. The coronary arteries are therefore subjected to the same elevation in systolic pressure as is the left ventricle, which probably accounts for the dilated appearance the coronary arteries may show in this condition.

A systolic ejection murmur is usually heard at the right upper sternal border and a systolic thrill may be present. The amplitude of the aortic closure sound is normal. Aortic diastolic murmurs are absent. The blood

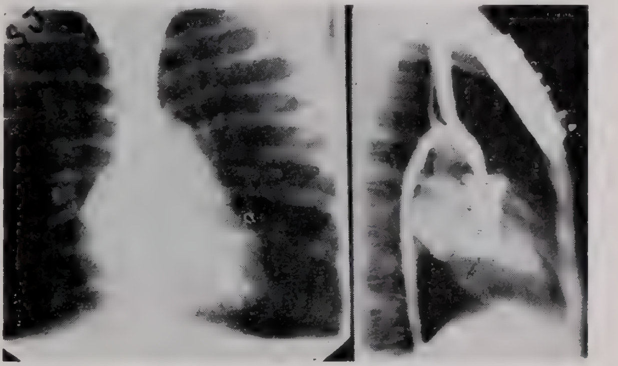

Fig. 3 — Retrograde supravalvular aortogram of a patient with supravalvular aortic stenosis. Left: posteroanterior view. Right: Lateral view. There is severe supravalvular aortic stenosis and tubular aortic hypoplasia.

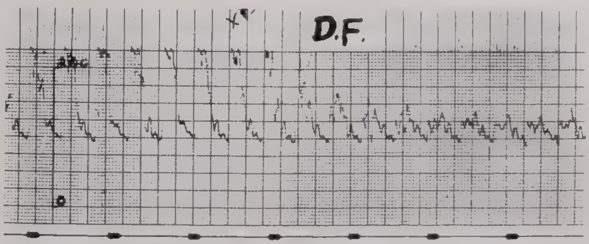

Fig. 4 — Withdrawal pressure tracing across the stenotic area of a patient with supravalvular aortic stenosis. A marked decrease in systolic pressure is recorded as the catheter tip is withdrawn across the area of supravalvular aortic stenosis into the aorta downstream to the obstruction.

---

*See Test Your Word Score, Page 1573.

pressure in the right arm is commonly higher than that in the left. This may be due to hypoplasia of the aortic arch branches or to the impact of the jet of blood caused by the obstruction.

Supravalvular aortic stenosis can comprise a part of a syndrome that in addition includes mental retardation, a characteristic facies, peripheral pulmonary artery stenosis and, in infants, hypercalcemia. As discussed by Jue and associates,[5] a patient may demonstrate all or some of the features which go to make up the complete syndrome. Figure 5 reproduces the pulmonary arteriogram of a patient with peripheral pulmonary artery stenosis as well as supravalvular aortic stenosis. Figure 6 shows the pressure tracing as the catheter tip is withdrawn from the pulmonary artery wedge position to the main pulmonary artery. A pressure gradient is evident as the catheter passes from the distal pulmonary artery segment, where the pressure is lower, across the stenotic area into the higher pressure segment proximal to the obstruction. The combination of supravalvular aortic stenosis and right ventricular or pulmonary arterial hypertension should alert one to the probability of peripheral pulmonary artery stenosis, especially if other features of the syndrome are present.

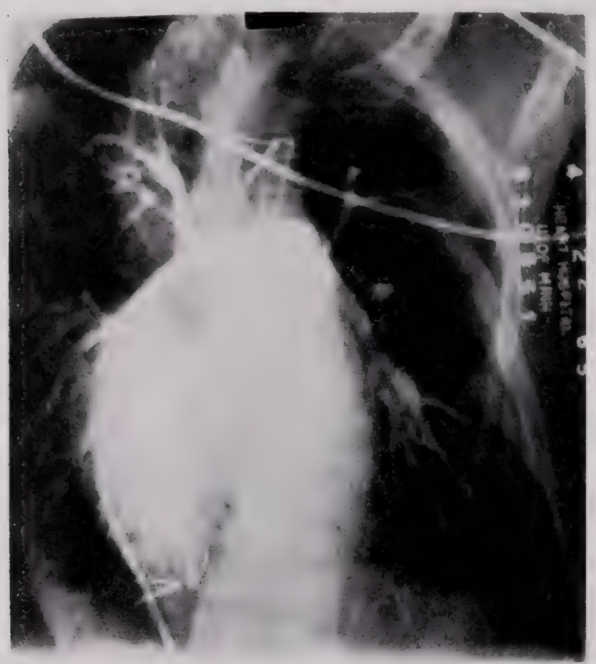

Fig. 5 — Pulmonary arteriogram of a patient with supravalvular aortic stenosis. There are multiple sites of peripheral pulmonary artery stenosis. Some vessels show post-stenotic dilatation.

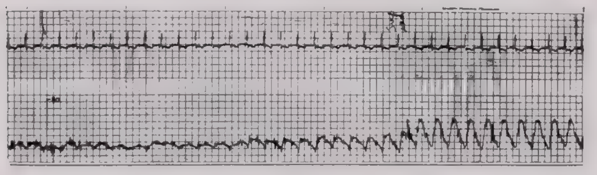

Fig. 6 — Continuous withdrawal pulmonary artery pressure tracing in a patient with peripheral pulmonary artery stenosis and supravalvular aortic stenosis. At the left the catheter tip is in the pulmonary artery "wedge" position and a normal venous type pressure is recorded. As the catheter is withdrawn, a pulmonary artery pressure of low amplitude is first seen. There is then an abrupt increase in systolic pressure as the catheter tip crosses the area of peripheral pulmonary artery stenosis and enters the segment of pulmonary artery proximal to the obstruction.

Subaortic Stenosis

Edwards has discussed the conditions which can produce subaortic stenosis.[2] All will show a pressure gradient across the obstruction as a result of the impediment to the forward flow of blood. Figure 7 shows the pressure gradient recorded in a patient with idiopathic hypertrophic subaortic stenosis. This variety of subaortic stenosis displays characteristic features not shared by the other types and caused by the dynamic nature of the obstructive process.[6] The stenosis results from the encroachment of septal and left ventricular muscle into the outflow tract of the left ventricle. During ventricular systole this muscular mass also contracts, constricting the outlet; in diastole the left ventricle relaxes and expands as it fills with blood. This explains why little or no narrowing of the outflow tract occurs in diastole.

Idiopathic hypertrophic subaortic stenosis is associated mainly with two other findings. Anatomic changes may occur in the mitral valve with resultant mitral insufficiency. Also hypertrophy of the wall of the right ventricle and interventricular septum will at times produce a similar dynamic obstruction in the right ventricular outflow tract.

Because of the muscular nature of the obstruction, variability is a characteristic feature in idiopathic hypertrophic subaortic stenosis. The magnitude of the obstruction and hence of the pressure gradient may vary and, indeed on occasion, an obstruction cannot be detected. Methods are available which will induce, increase, or abolish the systolic pressure gradient. These methods perhaps operate by altering the force of myocardial contraction, or the ventricular systolic volume, or both. It has recently been suggested[7] that the pressure gradient in idiopathic hypertrophic subaortic stenosis may not be related to an actual left ventricular outflow obstruction. According to this interpretation a segment of ventricle completely expells its contents in early systole. The high ventricular pressure is then produced by the continued systolic contraction of this portion of the ventricle about the catheter tip.

The systemic arterial pressure pulse often exhibits a characteristic contour. The upstroke of the pulse is more rapid than normal. In mid-systole there is a dip in the arterial pressure which paradoxically coincides with the point when the peak pressure is reached in the left ventricle. As the pressure in the left ventricle falls, a secondary rise in arterial pressure follows the preceding dip. The systemic arteries do not show this notched systolic contour in valvular aortic or discrete subaortic stenosis.

The response of the beat following a premature ventricular contraction has been found to be helpful in the diagnosis of idiopathic hypertrophic subaortic stenosis. The post-extrasystolic beat is associated with a widened peripheral arterial pulse pressure in the normal and in patients with valvular aortic and discrete subaortic stenosis. In idiopathic hypertrophic subaortic stenosis the response of the post-extrasystolic beat is abnormal in that the pulse pressure is the same as or less than that of the regular control beat. This is illustrated in the right hand panel of Figure 7. Patients with this disorder who at the moment have no detectable pressure gradient may develop a large gradient with the post-extrasystolic beat.

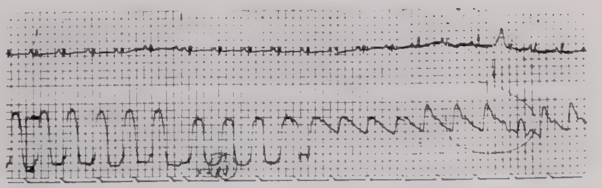

Fig. 7 — Discontinuous left ventricular, aortic, and brachial artery pressure tracings from a patient with idiopathic hypertrophic subaortic stenosis. Left: Left ventricular pressure tracing with the catheter tip positioned toward the apex. Center: Withdrawal pressure tracing from the outflow tract of the left ventricle to the aorta. There is a small systolic pressure gradient between the apex and outflow tract of the left ventricle but none across the aortic valve. Right: Brachial artery pressure tracing. The fourth beat from the right is a premature ventricular contraction. The pressure pulse associated with the post-extrasystolic beat shows a prominent mid-systolic dip in the pressure and a pulse pressure which is less than that of the control beats. The beat following the post-extrasystolic contraction still shows a visible, though smaller, mid-systolic dip in the pressure. These features are considered typical of idiopathic hypertrophic subaortic stenosis.

A systolic murmur is almost always present in idiopathic hypertrophic subaortic stenosis, sometimes accompanied by a thrill. In contrast to the other forms of left ventricular outflow obstruction where the murmur is located more at the base, in this condition the murmur is usually at the left sternal border or at the apex. A paradoxical splitting of the second heart sound and a fourth heart sound may be noted.

Roentgenographic examination may also be helpful. Cardiomegaly may be present. Aortic valvular calcification is absent, and dilatation of the ascending aorta is not present or is minimal.

Progress is just the slow business of falling in line with the schemes of minorities. — Wheeling Intelligencer

WHAT'S YOUR DIAGNOSIS?

A 60-year-old white female presented herself in her doctor's office complaining of abdominal discomfort for the past three weeks. She described her distress as a constant, "gnawing pain," located in the epigastric area with occasional radiation or spread to the right subcostal area. The pain was not related to or relieved by food. Stools were regular but for two weeks had been pale yellow in color. No weight loss had been noted. The past medical history was negative; she had never had an operation. She smoked about one package of cigarettes a day and used alcohol moderately. Examination revealed a healthy white female. The liver edge was palpable three centimeters below the right costal margin. Ascites was suspected, but the remainder of the examination was negative. No jaundice was noted and serum bilirubin was 0.83 direct, 0.81 indirect, total 1.64 mg%. An upper G.I. study and cholecystogram were normal. There was no anemia.

The epigastric pain remained constant but became more severe. There was no back pain. She was admitted to the hospital six weeks after the onset of her first symptoms. She then complained of abdominal bloating, enlargement of the abdomen and anorexia for two weeks. Jaundice was noted on her admission examination. The liver edge was down six centimeters and was tender. Shifting abdominal dullness was observed. No telangiectases were found. Proctoscopic examination was negative. Barium enema examination was normal.

Laboratory data: Hgb. 14.1 Gm%
wbc. 6470
Urinalysis negative
Prothrombin activity 56% of normal
BUN. 6.25 mg%
Serum bilirubin direct 3.2
indirect 1.4
Total 4.6
Alkaline phosphatase 9.7 King Armstrong units
Serum transaminase 113 units (normal range 10-40 units)
Sedimentation rate 34 mm/hour
Stool for occult blood — trace
LDH 195 units (normal range 60-120)
Cephalin flocculation negative at 24 and 48 hrs.

The consultant agreed that abdominal exploration and liver biopsy was indicated. Ten days after admission the abdomen was explored.

What's Your Diagnosis? Turn to page 1559.

Gulliver's Travels — Jonathan Swift*

Gulliver — On Wine

"Wine was not imported among us from foreign countries, to supply the want of water or other drinks, but because it was a sort of liquid which made us merry, by putting us out of our senses; diverted all melancholy thoughts, begat wild extravagant imaginations in the brain, raised our hopes, and banished our fears; suspended every office of reason for a time, and deprived us of the use of our limbs, until we fell into a profound sleep; although it must be confessed, that we always awaked sick and dispirited; and that the use of this liquor filled us with diseases, which made our lives uncomfortable and short." — Heritage Press, 1940.

On Quaffing

The trouble with people who drink like fishes is that they don't drink what fishes drink. — Louisville Courier-Journal

Antihypertensive Therapy in Clinical Practice

RICHARD MOYER, M.D.[*]
Hibbing, Minnesota

THIS STUDY was undertaken in order to evaluate the effectiveness, benefits, and complications of antihypertensive therapy in an unselected group of patients as seen in the private practice of internal medicine. It is felt that much of this study's significance relates to the clinical realism of its conditions: an unselected group of hypertensive patients examined and treated in standard clinical surroundings.

Reports of a number of recent studies have recommended polythiazide[**] for long-term management of hypertension and its attendant disorders, with minimal incidence of side effects and complications.[1-6] This drug, therefore, was selected to initiate therapy.

Methods and Materials

Patients

Fifty-two patients were chosen at random from a private office practice. Two were dropped from the study because of possible drug reactions. In the remaining 50 patients, there were 21 females and 29 males, ranging in age from 34 to 75 years. The majority had had hypertension of long standing and had been referred as failures on previous treatment. Thirty-two of the 50 had been treated with an agent other than polythiazide prior to this study; 18 patients had not been treated previously.

A minimum diastolic pressure of 100 mm. mercury was recorded on at least two examinations before each patient was included in the study group. The patients were then classified in three groups according to the severity of hypertension indicated by blood pressure:

Mild (100 to 109 diastolic)	Eight patients.
Moderate (110 to 119 diastolic)	Eighteen patients.
Severe (120 diastolic)	Twenty-three patients.

---

[*] Mesaba Clinic

[**] Supplied as Renese, by the Medical Department of Pfizer Laboratories.

Eight patients had definite cardiac, renal, or cerebral complications prior to the initiation of therapy. (See Table 1.)

TABLE I

Myocardial Infarctions	Recent	2
Myocardial Infarctions	Old	2
Cardiac Failure	(At Onset of Treatment)	1
Cerebral Vascular Accidents		2
Chronic Renal Disease	(Elevated BUN.)	1

Clinical Studies

On each patient's visit a general physical examination was performed with special attention to evaluation of the eyegrounds, character of peripheral pulses, presence of abdominal or cervical bruits and cardiac examination. Patients were closely questioned as to family, history of cardiovascular disease, diabetes or gout, cerebral, renal or cardiac symptoms. Each patient was examined on at least two occasions before antihypertensive therapy was initiated. The patients were then seen at intervals consistent with the severity of their blood pressure and their response to medication. On each subsequent visit the blood pressure was taken in both arms in the sitting position, also in the standing position in any patients taking sympatholytic drugs.

Laboratory Procedures

Routine tests performed at the beginning of therapy for each patient covered c.b.c. and urine, chest x-ray, EKG., BUN., cholesterol, and fasting blood sugar. Uric acid was also examined and a colorimetric screening test* used to detect urinary infections. All blood pressures were taken by the investigator; all laboratory work was performed consistently by the same technicians. Qualified radiologists interpreted the chest x-rays, and a single observer read all electrocardiograms. (See Table 2 for previous therapy.)

Treatment of Hypertension

The initial dose was either 1 or 2 mg. of polythiazide per day, as determined by the severity of the blood pressure. This dosage was subsequently increased, when necessary, to a maximum of 4 mg. daily. If optimal blood pressure control was not achieved within 30 days, a second drug was added to the program — usually guanethidine** or methyldopa.†. A Rauwolfia compound was also found to be a very useful second drug when anxiety or tension played a significant role in a case. When adequate control of the hypertension had been maintained for two to three months, the drug dosages were decreased at two or four-week intervals, until the minumum dosage necessary to maintain control was reached. Diets were instituted for overweight patients, and all patients were instructed to follow a one-gram sodium diet.

The criterion used to evaluate the results of therapy was diastolic pressure. When this was 90 mm. mercury or lower, the result was considered excellent; between 91 and 100, fair, and over 100, poor.

Results

Of the total 50 patients, 43 (or 86%) showed excellent response to therapy; seven patients (14%) had fair response; there were no poor results.

A fall in diastolic pressure was noted in all 50 patients, the average fall being 26 mm. mercury. In addition, a significant drop in systolic pressure was noted for all 50 patients, an average drop of 50 mm. mercury.

In 12 cases it was possible to reduce the polythiazide dose while retaining control of blood pressure. This reduction was quite impressive in many patients who initially required 4 mg. daily and were eventually controlled on ½ mg. every other day. In two patients the drug was stopped for a period of two months with no rise in blood pressure during that period. Subsequently, a rise in blood pressure required very small doses of polythiazide. One patient, who developed diabetes mellitus during the treatment period and who was in cardiac failure prior to treatment, has remained out of failure and controlled for a period of four months after discontinuing polythiazide.

Twenty-five patients were maintained on 4 mg. of polythiazide, 10 patients on 2 mg., nine on 1 mg., and five on less than 1 mg. daily.

*Uroscreen, Charles Pfizer and Company.

**Ismelin

†Aldomet

Nine patients required additional hypotensive agents due to inadequate control. (See Table 3.)

In three patients with original cardiac enlargement, there was a decrease in cardiac size demonstrable by x-ray. In four patients there was definite improvement in electrocardiograms.

An initial rapid loss of three to eight pounds was a usual finding; however, this weight was frequently regained over the next two to three weeks. Twenty-nine patients lost an average of 16 pounds over the entire study period; six gained an average of eight pounds, and 15 experienced no weight change.

Side Effects and Complications

In general the drug was very well tolerated. When large doses of polythiazide were used initially, malaise, weakness and rapid weight loss were common findings. However, if smaller doses of the drug were used initially, followed by an increase in dose, characteristic weight loss occurred more slowly and symptoms were negligible. The most efficacious initiating dose was 2 mg. for severe hypertension and 1 mg. for mild to moderate elevations of blood pressure.

Two patients were dropped from the study because of initial side reactions. The first reaction consisted of a rather ill-defined syndrome of tingling extremities, malaise, and weakness associated with impotence. The second patient, who had a chronic neurodermatitis prior to therapy, developed a generalized maculopapular* eruption that was resistant to therapy. Both of these reactions cleared after cessation of polythiazide. However, the investigator did not feel it prudent to challenge these two patients with the drug at a subsequent date.

There was a rather surprising increase in uric acid in 56% of the group, the average increase for the 28 patients being 2.41 mg. However, only two patients experienced any joint symptoms, obviously gout. One of them had had gout prior to initiation of polythiazide. Both were rather easily controlled by probenicid and colchicine, plus a diminution of the polythiazide dose. There was no increase in cholesterol accompanying the uric acid elevations. Two patients required potassium supplements because of symptoms referable to hypopotassemia.

Frank diabetes appeared in two patients, both of whom had normal blood sugars prior to therapy. The first of these patients, a 65-year-old white male with moderate hypertension, had an excellent response to polythiazide, his systolic pressure falling 40 mm. mercury and his diastolic pressure 15 mm. mercury. There was also a weight loss of 20 pounds. Thirteen months after initiation of therapy, glycosuria was noted; blood sugar was found to be 300 mg. per cent. Polythiazide was then discontinued and chlorpropamide** instituted. The diabetes was easily controlled and, interestingly, the patient's blood pressure remained under control on no

**Diabenese, Charles Pfizer and Company.

specific antihypertensive therapy for six weeks, the diastolic pressure then gradually rising to 100 mm. mercury.

The second diabetic patient was a 73-year-old white female, who was in left and right-sided cardiac failure when first seen. She had a mild blood pressure elevation, which fell 40 mm. systolic and 15 mm. diastolic with therapy. There was also a concomitant 35-pound weight loss. After 32 months a routine urinalysis showed glycosuria; blood sugar was 310 mg. per cent. Thiazides were discontinued, and she was easily controlled on small doses of chlorpropamide. She has remained out of failure and her blood pressure under control, for four months at the time of this report.

One patient was found to have diabetes and cardiac failure when first seen. He was easily controlled on chlorpropamide, while taking thiazides. A moderately elevated BUN. in one patient returned to normal on a decreased dosage, with no loss of blood pressure control.

Summary

A random group of 50 hypertensive patients have been most satisfactorily controlled and observed for one to three years with polythiazide as the sole hypotensive agent or as the cornerstone of therapy. Whether used as the sole hypotensive agent or in a multiple drug regime, in all but one case it was more effective than previous therapy. Eighty-six per cent of the patients showed excellent response to therapy; 14% showed fair response.

Fifty-six per cent of the group had elevated uric acids, with only two patients manifesting gouty symptoms. Precipitation of latent gout, diabetes, and hypokalemia are relatively common complications and should be sought assiduously in treatment with thiazides.

Commentary

A considerable number of these patients (24%), after blood pressure had been controlled for several months, could be maintained on significantly lower doses of thiazide. One patient has maintained a normal blood pressure for four months since polythiazide was discontinued.

One of the two patients dropped from the study group because of a dermatitis was resistant to multiple drug treatment; he was later controlled on a combination of polythiazide and Rauwolfia without side effects.

Acknowledgment

This work was supported in part by grants from the Minnesota Heart Association and Charles Pfizer and Company.

I am indebted to Mrs. Antonette Mestnick, Mrs. Angeline Johnson and Miss Sharon Sampson for their invaluable assistance.

Derivatively Speaking

The juice formed by the liver may be called either bile or gall. *Bile* comes from the Latin word "bilis," which is what the Romans called the juice, but *gall* is Anglo-Saxon in origin. Both words are used in combination with others, and the choice of which to use depends on the derivation of the other word.

For instance, the juice is stored in a small pear-shaped bag called a *gall bladder* (never a "bile bladder," since *bladder*, like *gall*, is of Anglo-Saxon derivation), and is led into the intestines by means of a *bile duct* (never a "gall duct," since *duct* is from the Latin "ducere" meaning "to lead").

Hypocholesterolemia

DEWITT T. HUNTER, M.D.*
Salt Lake City, Utah

THOSE DISEASES and conditions associated with elevated serum cholesterol levels are well documented,[1] and it is to evaluate hypercholesterolemia that the serum cholesterol assay is most frequently performed. Less is known about hypocholesterolemia and its significance in disease. A study was undertaken to ascertain the diagnostic value of decreased serum cholesterol levels.

It is general knowledge that hyperthyroidism[2] and certain hepatic parenchymal disorders[3] are frequently associated with low serum cholesterol values. The diagnostic significance of lowered serum cholesterol in other disease states has been largely discounted. A detailed interpretation of hypocholesterolemia is advanced by Kolmer[4] in which 22 specific diseases are cited as a cause of, or associated with, decreased serum cholesterol. Several isolated articles have stressed the diagnostic significance of low cholesterol values in low fat ingestion,[5] rheumatic disease,[6] steatorrhea,[7] hypopituitary disease,[8] terminal stress,[9] anemia, infection,[6] pancreatitis,[10] and strenuous exercise.[11] In addition, various types of medication have been shown to depress serum cholesterol.[12]

Materials and Methods

Over 750 consecutive, low (less than 150 mg/100 ml.) cholesterol values were compiled, the determinations performed by the method of Abell. Values below 150 mg/100 ml. represented 3.4% of the total serum cholesterols assayed during the period of study. Approximately 90% of the specimens were drawn from hospital in-patients and the remainder from out-patients. Females accounted for 54% of the group. It is to be emphasized that this general hospital population was selected, since the presumptive diagnoses of these patients at the time the test was requested generally included hepatic diseases, thyroid diseases, and arteriosclerosis. Certain of the patients were diagnostic problems. The charts of all were studied and the diagnoses tabulated and analyzed. Only proven diagnoses were included in this final evaluation. Autopsies were performed on 3.3% of the population. Most of the patients had more than one diagnosed disease process.

---

*Director, Clinical Laboratories, University of Utah.

To assist in evaluating *specific* cause and effect vs. *nonspecific* effect, the following empirical formula was used to "quantitate" any significant relationship that might exist between a given disease and the serum cholesterol level.

$$\frac{A \times B \times C \times D}{E} = \text{Factor of Relative Significance}$$

A = % of patients with some form of disease under consideration. This parameter is of obvious importance. In any determination, regardless of mechanism, specificity or frequency, if a given disease accounts for a high percentage of abnormal results, it must be given consideration in interpretation of results.

B = % of patients with some form of disease under consideration and no known additional concurrent disease process. If a patient has only one disease process and an abnormal test value, the probability is great that the abnormal result is related to the single disease process.

C = % of patients with some form of disease under consideration and at least one additional disease known to *elevate* serum cholesterol levels (biliary disease, myxedema, diabetes). It is logical to assume that any disease process occurring with a low-test value in a patient with a second disease known to "cause" high test values probably has considerable "cause-effect" significance.

D = approximate % of patients with some form of disease under consideration known to manifest hypocholesterolemia (for example 16% of patients with parenchymal disease of the liver have low serum cholesterol[10]). Obviously, if 90% of patients with a given disease had an abnormal test result, the degree of specifiicity and significance would be greater than if only 10% usually showed this abnormality. The figures used in this study were obtained, where possible, from the literature or estimated from hospital discharge statistics.

E = % of patients with some form of disease under consideration and at least one disease known to *depress* serum cholesterol (hyperthyroid disease, malabsorptive disorders, parenchymal disease of the liver). In the presence of a disease suspected of having an active effect on a given test value the similar effect of other diseases is open to question. Therefore the correlation is considered negative or reciprocal instead of cumulative, as with the foregoing situations.

Diseases showing frequency of less than 2.8% were not subjected to analysis since theoretically significant results would be invalid. The magnitude of cholesterol depression was not considdered in the formulation because no definite pattern of change was manifest. The mean cholesterol level for different diseases varied insignificantly from the total mean value.

Assuming that in a clinically well population 5% of the group would have cholesterols below 150 mg. per 100 ml. and conferring values of 1% to category C and E, a normal person with a low serum cholesterol would receive a Factor of Relative Significance of 125.

Results

On the basis of the results obtained from this formula, certain diseases or conditions apparently had an *active* cause or effect relationship on cholesterol levels, and other diseases apparently had a *passive* or incidental association. The figure 250 was considered the dividing line between significant and nonsignificant disease states. This figure was selected primarily because it was twice the value of the figure calculated for the theoretical normal person. These figures are tabulated in Table 1.

Of the incidental observations obtained in the study, the following deserve consideration.

1. The lower limit of normal usually quoted for serum cholesterols in American populations is probably too high for infants and for extremely elderly people, and too low for adults in the 20 to 60-year age group.[14] A more realistic lower limit of normal for this latter group would be 160 mg%. This conclusion is based on the fact that over 99.5% of the adult population in the study were clinically ill.

*Not Significant.

2. Patients with genitourinary infections apparently have a higher incidence of hypocholesterolemia than patients with other types of infections. In many cases the genitourinary infection is either very mild or quiescent.

3. The incidence of hypocholesterolemia in diabetics was approximately four times higher in those patients with Kimmelstiel-Wilson involvement of their kidneys than in uncomplicated diabetics.

4. 11.9% of patients with low cholesterol had some form of collagen disease. Approximately twice this number of additional patients had certain symptoms and laboratory results that were best explained by collagen vascular disease, but did not have a proven diagnosis at the time of study. All auto-immune disorders were represented in this group.

5. All patients with hypocholesterolemia and myxedema had an associated collagen disease, hypopituitary disease, or recent thyroidectomy.

6. A patient with a rare oxyphil* adenoma of his parathyroid gland had an elevated cholesterol level prior to operation and a persistently decreased cholesterol after removal of the tumor.

7. Anemia, chronic infections, heart disease, terminal malignancy, chronic enteritis, diabetes and uremia were inactive in lowering serum cholesterol.

8. Free-ester cholesterol fraction rarely contributes useful information in hypocholesterolemic conditions. In all except two instances the free-esterified ratio was within normal limits. Both of these patients had abdominal malignancies which had massively infiltrated the mesenteric lymphatics.

Discussion

Factors detracting from the clinical significance attending serum cholesterol values are: variable technical results giving standard deviations of up to ± 10% ; wide variation of normal values relative to environment, general state of health, age, sex, inactivity, differences in technical methods, and dietary habits; and poor diagnostic correlation with disease processes. Many observers feel that assay of other serum lipid fractions contribute more useful information. Others point out that fluctuations are extremely nonspecific, and that the changes cited above are more frequently responsible for serum cholesterol variations than are the basic disease processes.

A compilation of lower limits of serum cholesterol defined by 15 investigators ranges from 97 to 190 mg/100 ml. These studies were performed on a total of 4313 "normal" American people of both sexes between the ages of 17 and 78 years of age. The mean cholesterol lower limit was 150.2 mg/100 ml. Several of these investigators indicated that their figures were based on division at the second standard deviation level. The lower limit of normal of the Abell procedure is 150 mg/100 ml. The standard variation of paired samples is within ± 5%.

It is difficult in this study to adequately evaluate the nonspecific effects of secondary starvation, prolonged bed rest, inactivity, and inanition on serum cholesterol level. Conclusive studies would involve complete dietary analysis, nitrogen balance studies, and serial lipid assays.**

The results of this study do not appreciably extend the diagnostic value of serum cholesterol determinations except for the apparent significant relationship of genitourinary infections and collagen vascular diseases to hypocholesterolemia. The negative contribution in instances of diabetes, chronic infections, heart disease, anemia, nonpancreatic gastrointestinal disease, and terminal disease including malignancy may have value in the implication and diagnosis of complicating disease processes.

Summary

A study was made of 750 patients with hypocholesterolemia. Thyroid hyperfunction, parenchymal disease of the liver, pancreatic insufficiency, profound low-fat diets, hypofunction of pituitary and adrenal glands, and collagen vascular diseases are the principal groups of diseases associated with active serum cholesterol reduction. Infections, anemia, terminal malignancy, heart disease, diabetes, and intestinal disorders appear to be only secondarily related to hypocholesterolemia.

---

*See Test Your Word Score Page 1573.

**It is probable that these nonspecific factors would neutralize themselves by affecting all disease states equally.

Desiderata*

Go placidly amid the noise and the haste, and remember what peace there may be in silence. As far as possible without surrender be on good terms with all persons. Speak your truth quietly and clearly; and listen to others, even the dull and ignorant; they too have their story. Avoid loud and aggressive persons, they are vexations to the spirit. If you compare yourself with others you may become vain and bitter; for always there will be greater and lesser persons than yourself. Enjoy your achievements as well as your plans. Keep interested in your own career, however humble; it is a real possession in the changing fortunes of time. Exercise caution in your business affairs; for the world is full of trickery. But let this not blind you to what virtue there is; many persons strive for high ideals; and everywhere life is full of heroism. Be yourself. Especially do not feign affection. Neither be cynical about love; for in the face of all aridity and disenchantment it is as perennial as the grass. Take kindly the counsel of the years, gracefully surrendering the things of youth. Nurture strength of spirit to shield you in sudden misfortune. But do not distress yourself with imaginings. Many fears are born of fatigue and loneliness. Beyond a wholesome discipline, be gentle with yourself. You are a child of the universe no less than the trees and the stars; you have a right to be here. And whether or not it is clear to you, no doubt the universe is unfolding as it should. Therefore be at peace with God, whatever you conceive Him to be, and whatever your labors and aspirations, in the noisy confusion of life keep peace with your soul. With all its sham, drudgery and broken dreams, it is still a beautiful world. Be careful. Strive to be happy.

M.M.

Many overweight patients can benefit from the appetite control provided by the sustained anorexigenic-tranquilizing action of BAMADEX SEQUELS: anorexigenic action of amphetamine; tranquilizing action of meprobamate; prolonged action through sustained release of active ingredients.

Bamadex® Sequels®

DEXTRO-AMPHETAMINE SULFATE (15 mg.)
WITH MEPROBAMATE (300 mg.)
SUSTAINED RELEASE CAPSULES

to help establish a new dietary pattern

Contraindications: Dextro-amphetamine sulfate: in hyperexcitability and in agitated prepsychotic states. Previous allergic or idiosyncratic reactions to meprobamate.

Precautions: Use with caution in patients hypersensitive to sympathomimetic compounds, who have coronary or cardiovascular disease, or are severely hypertensive.

Dextro-amphetamine sulfate: Excessive use by unstable individuals may result in psychological dependence.

Meprobamate: Careful supervision of dose and amounts prescribed is advised, especially for patients with known propensity for taking excessive quantities of drugs. Excessive and prolonged use in susceptible persons, e.g. alcoholics, former addicts, and other severe psychoneurotics, has been reported to result in dependence on the drug. Where excessive dosage has continued for weeks or months, reduce dosage gradually. Sudden withdrawal may precipitate recurrence of preexisting symptoms such as anxiety, anorexia, or insomnia; or withdrawal reactions such as vomiting, ataxia, tremors, muscle twitching and, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, reduce dosage and avoid operation of motor vehicles, machinery or other activity requiring alertness. Effects of excessive alcohol consumption may be increased by meprobamate. Appropriate caution is recommended with patients prone to excessive drinking. In patients prone to both petit and grand mal epilepsy meprobamate may precipitate grand mal attacks. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side Effects: Overstimulation of the central nervous system, jitteriness and insomnia or drowsiness.

Dextro-amphetamine sulfate: Insomnia, excitability, and increased motor activity are common and ordinarily mild side effects. Confusion, anxiety, aggressiveness, increased libido, and hallucinations have also been observed, especially in mentally ill patients. Rebound fatigue and depression may follow central stimulation. Other effects may include dry mouth, anorexia, nausea, vomiting, diarrhea, and increased cardiovascular reactivity.

Meprobamate: Drowsiness may occur and can be associated with ataxia; the symptom can usually be controlled by decreasing the dose, or by concomitant administration of central stimulants. Allergic or idiosyncratic reactions: maculopapular rash, acute nonthrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever, transient leukopenia. A case of fatal bullous dermatitis, following administration of meprobamate and prednisolone, has been reported. Hypersensitivity has produced fever, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, stomatitis, proctitis (1 case), anaphylaxis, agranulocytosis and thrombocytopenic purpura, and a fatal instance of aplastic anemia, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity, usually after excessive dosage. Impairment of visual accommodation. Massive overdosage may produce drowsiness lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

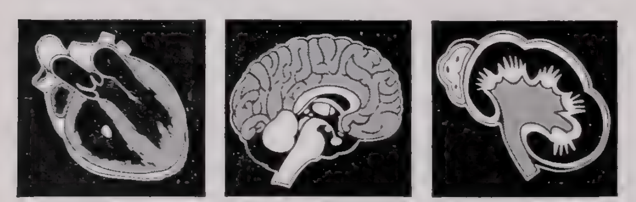
SQUIBB NOTES ON THERAPY

Behind continued high blood pressure readings lies the possibility of organic damage[1-13]

MANY OF THE aspects of essential hypertension are unpredictable—either because there are a number of mechanisms involved or because individuals differ in their responses to these mechanisms.[1]

There is one aspect of hypertension, however, that seems, in many cases, predictable. ". . . when the blood pressure is elevated to a marked degree for an adequate period of time, this in itself leads to perpetuation of the syndrome with resulting vascular damage throughout the body."[14] All too often the disease progresses until there is damage to one of three vital organs: the heart, the kidney, the brain.



> "Hypertension is certainly a major factor in the genesis of coronary heart disease, and it is even more important when compounded with obesity."[4]
>
> "[Vascular deterioration] can be clearly seen in the kidney with a degree of damage that can be measured by renal function studies."[10]

". . . most evidence suggests that reduction of blood pressure, when it is too high, not only relieves the heart of excess work but reduces vascular damage."[1]

"In short, treatment is indicated."[1]

Antihypertensive therapy will not restore the blood vessels to normal. Yet many of the vascular changes and symptoms caused by increased blood pressure may be arrested or alleviated when the blood pressure is reduced to normotensive levels.[7]

Reducing the blood pressure helps curtail further vascular damage and improves the prognosis — when damage is not too far advanced before therapy is started.[14] Essential hypertension is an indication not only for treatment, but for *early* and adequate treatment of the patient in question.

Reduce the blood pressure with Rautrax-N

Rautrax-N combines the antihypertensive-tranquilizing action of whole root rauwolfia with the antihypertensive-diuretic action of bendroflumethiazide in one convenient medication. The two drugs complement each other so that smaller doses of both are possible.

Rauwolfia combined with bendroflumethiazide is particularly effective in long-term therapy,[15-17] since beneficial effects do not diminish with continuous daily administration.

For most patients 1 or 2 Rautrax-N tablets daily are sufficient for maintenance therapy. The simplicity, convenience and economy of such a dosage schedule are of particular benefit to older patients.

Contraindications: Severe renal impairment or previous hypersensitivity. **Warning:** Ulcerative small bowel lesions have occurred with potassium-containing thiazide preparations or with enteric-coated potassium salts supplementally. Stop medication if abdominal pain, distension, nausea, vomiting or G.I. bleeding occur.

Precautions and Side Effects: The dose of ganglionic blocking agents, veratrum or hydralazine when used concomitantly must be reduced by at least 50% to avoid orthostatic hypotension. Caution is indicated in patients with depression, suicidal tendencies, peptic ulcer; electrolyte disturbances are possible in cirrhotic or digitalized patients. Marked hypotension during surgery is possible; consider discontinuing two weeks prior to elective surgery and observe patients closely during emergency surgery. Rauwolfia preparations may cause reversible extrapyramidal symptoms and emotional depression, diarrhea, weight gain, edema, drowsiness may occur. Bendroflumethiazide may cause increases in serum uric acid, unmask diabetes, increase glycemia and glycosuria in diabetic patients, and may cause hypochloremic alkalosis, hypokalemia; cramps, pruritus, paresthesias, rashes may occur.

Dosage and Supply: Initial dosage, 1 to 4 tablets daily, preferably at mealtime. Maintenance, 1 or 2 tablets daily. Rautrax-N is supplied as capsule-shaped tablets containing 50 mg. Rauwolfia serpentina whole root (Raudixin®), 4 mg. bendroflumethiazide (Naturetin®), 400 mg. potassium chloride.

Also available: Rautrax-N Modified — capsule-shaped tablets containing 50 mg. Rauwolfia serpentina whole root (Raudixin), 2 mg. bendroflumethiazide (Naturetin), 400 mg. potassium chloride. Both potencies available in bottles of 100. For full information, see Product Brief.

RAUTRAX®-N

Squibb Rauwolfia Serpentina Whole Root (50 mg.) with Bendroflumethiazide (4 mg.) and Potassium Chloride (400 mg.)

Meniere's Disease*

ENDOLYMPHATIC HYDROPS, or hypertension of the labyrinth, remains a great unsolved problem in the practice of otology. The causes of this condition are obscure and treatment by medical means has been as variable as the theories proposed for an explanation of the increased endolymphatic pressure.

Symptomatic improvement can be expected in most cases with judicious medical treatment and psychotherapy, or by spontaneous remission. The occasional severe case which has failed to respond to medical management and presents a persistence or recurrence of disabling vertigo with severe hearing loss requires surgical intervention.

One feature of this condition, which is more commonly referred to as Meniere's disease, has been definitely established. This is the gross distention of the endolymphatic system, along with degenerative changes in the Organ of Corti. The relationship between increased endolymphatic pressure and the typical hearing loss of Meniere's disease has also been clarified and established. Experiments have demonstrated that increasing the endolymphatic pressure in animals by injection of a hypertonic solution into the scala media results in a decrease of cochlear potentials and a return to normal upon release of the pressure.

Intractable vertigo with severe permanent hearing loss resulting from Meniere's disease has been treated surgically by various procedures employing a direct attack on the labyrinth for the purpose of destroying the endolymphatic system and indirectly affecting also the cochlea resulting in hearing loss. Neurosurgical section of the eighth cranial nerve has been replaced by the safer methods of opening the horizontal semicircular canal or the oval window within the middle ear, by transtemporal bone approach, to extract the endolymphatic labyrinth. These procedures have been used only in cases which have precluded a profound hearing loss with a disabling vertigo. Where useful hearing is still present, and especially when both ears are involved with hydrops of the labyrinth, it becomes desirable and hopeful to attempt relief of vertigo without destroying the residual hearing function.

Ultra-sound applied to the bony horizontal semicircular canal has been used and can affect relief of vertigo, but the result may not be permanent and in many cases facial paralysis has resulted. An approach through the stapes footplate to reach the labyrinth and relieve pressure of endolymph

"All Interns are Alike"

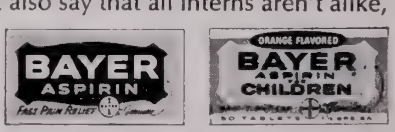
It stands to reason. They all go through the same training; they all have to pass the same tests; they all have to measure up to the same standards; they all are underpaid, too. Therefore, all interns are alike.

That's utter nonsense, of course. But it's no more nonsensical than what some people say about aspirin. Namely: since all aspirin is at least supposed to come up to certain required standards, then all aspirin tablets must be alike.

Bayer's standards are far more demanding. In fact, there are at least *nine specific differences* involving purity, potency and speed of tablet disintegration. These Bayer® standards result in significant product benefits including gentleness to the stomach, and product stability that enables Bayer tablets to *stay* strong and gentle until they are taken.

So next time you hear someone say that all aspirin tablets are alike, you can say, with confidence, that it just isn't so.

You might also say that all interns aren't alike, either.



by penetration of the dilated saccule with a perforating hook has been used. With this technique, however, as in other procedures using a direct attack on the labyrinth, a large percentage of cases result in increased hearing loss.

Drainage of the saccus endolymphaticus has been described for some time as the logical type of treatment of Meniere's disease. The difficulties encountered in many procedures designed for drainage of endolymph are related to accurate identification of the saccus and subsequent fibrotic growth hindering continued escape of endolymph. It has become evident that simple drainage of endolymph affords only temporary relief of vertigo and that the longer drainage can be maintained, the longer the patient will be free of symptoms.

Experiments now indicate that the buildup of excessive endolymphatic pressure as a cause of Meniere's disease is probably due to a faulty absorption mechanism rather than an acute pathologic process in the endolymphatic system. Creation of a permanent fistula to aid or correct this disturbed fluid balance seems therefore to be a sound and more effective physiologic approach to the problem of maintaining permanent relief of endolymphatic pressure.

Anti—Nuclear Antibodies in Various Diseases*

THE SIGNIFICANCE of the numerous antinuclear factors which have been discovered in the serum in various diseases is still not clear after almost two decades of investigation. These antibodies were initially found in the course of studies on the nature of the lupus erythematosus (LE) factor which subsequently was discovered to be γ-globulin. A number of antibodies have since been identified, which react with deoxyribonucleoprotein (DNP), deoxyribonucleic acid (DNA), a glycoprotein extracted from whole nuclei by isotonic neutral buffers, nucleoli (possibly RNA), histone (the protein moiety of DNP), and microsomes and mitochondria, the antigenic parts of which have not yet been determined. Of these, only anti-DNA has been found to be specific. It is present only in patients with disseminated lupus erythematosus, and the amount present varies directly with the severity and acuteness of the disease. Its presence can be detected by complement fixation, by immune precipitation, by a fluorescent-spot technique, or by a characteristic "shaggy" pattern of the nuclei of leukocytes coated with this antibody and then developed with fluorescent anti-human γ-globulin.

The most commonly found antibody is anti-DNP, the antibody probably studied by Gokcen, Peterson, and Ehrnst.* This antibody is present in a wide variety of inflammatory disorders and in diseases characterized by tissue necrosis. The finding of such reactivity in patients with tumors, as reported by these authors, suggests that when the test is set at a very sensitive level this reactivity is diagnostically not much more helpful than any other acute-phase reactant. Its presence does not necessarily imply that any auto-immune reaction is causing the patient's symptoms.

In fact, it is very unlikely that anti-nuclear antibodies themselves cause any direct harmful effects on cell nuclei, as they do not cross the cell membrane of living cells. Anti-nuclear antibodies may react with dead or degenerated nuclear material and thus induce migration of polymorphonuclear leukocytes and an ensuing inflammatory response, but there is no good evidence at present that such a mechanism is actually important in any known human disease. The relationship of anti-DNP to the LE-cell-forming factor has not been worked out in detail; the LE factor does seem to be an anti-DNP antibody. Whether the fact that not all patients with anti-DNP give positive LE clot tests is due to quantitative differences in the

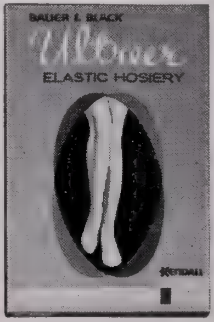
**You prescribe elastic stockings.
She won't wear them.
Now what?**

Ultreer™

Elastic Stockings so sheer they look like support hose. Both Ultreer and support hose are sheer, shapely, cool and comfortable. But that's where the similarities end. New Ultreer fits firmly and evenly over the entire leg. Gives true therapeutic compression necessary to relieve varicose veins and other leg disorders. They provide the therapy you prescribe. The fashion and economy she demands.
Ultreer stockings have a new low price. So low, she can afford two pairs of Ultreer instead of one pair of regular elastic stockings. There'll be no disagreements there. Ultreer stockings are as comforting to her purse as they are to her legs. New Ultreer are the elastic stockings doctors and women can agree on.



KENDALL
BAUER & BLACK SUPPORTS DIVISION

amount of antibody present or to other factors is not known. Not all patients with positive LE clot tests have detectable anti-DNP in their sera.

The high incidence (50%) of positive anti-nuclear tests in rheumatic fever in the series reported is also probably explained by the high sensitivity and low specificity of the test used. The authors stated that they are now titrating their sera, and the use of a semiquantitative test may improve the diagnostic usefulness of their method. However, since they did not examine any of the patients themselves but merely used the diagnoses on charts called from several hospitals and representing the opinions of a large number of physicians, it is impossible to have much confidence in the significance of their results.

Rochester, Minnesota

Macroglobulins, Microglobulins, and the New Terminology

THE ARTICLE by Bell and Neumann* reporting some studies on characterization of the macroglobulins found in a group of eight patients provides a vehicle enabling us to make a plea for rapid transition to the new terminology for immunoglobulins.[1] Massive increases in macroglobulins such as those found in Waldenström's macroglobulinemias, or in microglobulins — so called L-chains or Bence-Jones proteins (associated with multiple myeloma) — are actually exaggerations of normal constituents of the serum protein spectrum. The immunoglobulins — so-called because their primary function in body economy seems to be to carry or provide antibody specificity — have been called as many different names as some of our early 20th century political parties. Public awareness of their importance was apparent as long as a decade ago when, as Dr. Waldenström observed during a visit to Boston, angry mothers were picketing with signs announcing "We Want Gamma Globulin!". His first reaction, he told us, was "What a progressive country!".

The new nomenclature for the immunoglobulins has been proposed by the Bulletin of the World Health Organization and is quite simple. The old terms 7-S γ-globulin, gamma-2 globulins, γSS, γ-globulin (all meaning the same thing to the initiated fraternity of workers in this field) have been simplified to γG or IgG (immunoglobulin G). γG comprises 75-80% of the bulk of antibody molecules in human serum. The second major immunoglobulin class (old terms — gamma$_1$A, B$_2$A, β_2A) now goes by the simpler term γA or IgA. This second immunoglobulin class (10-15% of immunoglobulins) seems to be associated in many instances with skin reactivity and may be of special significance in conferring an unique immune system to the gastrointestinal tract. The third major immunoglobulin class (old terms — gamma$_1$M, macroglobulins, 19S-γ-globulins, heavy antibody) is now called γM or IgM. All three major groups of immunoglobulins IgG, IgA, and IgM are comprised of heavy (H) and light (L) polypeptide chains linked by disulfide bonds. Antigenic cross reactions occur among these three major immunoglobulin classes on the light chains which are identical to the microglobulins or Bence-Jones proteins often excreted in the urines of patients with multiple myeloma.

When sera such as those reported in the accompanying article by Bell and Neumann are matched with the clinical picture of the individual patients, it has been our general experience that many of the subjects studied fall into the general broad category of malignant lymphoma. This view is also borne out by the recent study of Krauss and Sokal.[2] In terms of the laboratory diagnosis of Waldenström's macroglobulinemia by far the quickest and most reliable technique is immunoelectrophoresis combined with quantitative assay of IgM using Oudin tube techniques[3] or analytical ultracentri-

PENTAZYME
DIGESTANT

An eight-year-old may not need digestive enzymes . . .

BUT troublesome gas, belching and cramps are common complaints of many patients regardless of age. PENTAZYME will give these patients fast relief when the diagnosis is enzyme insufficiency.

PENTAZYME offers 5 supplemental digestive enzymes in *one* enteric-coated tablet for release at the natural sites of action. Three tablets, the usual daily dose, will digest 50% of the starch, 40% of the protein and 20% of the fat in a balanced 2500 calorie diet.

For patients with short-term or chronic digestive problems, prescribe PENTAZYME.

For complete information and samples, write to Dept. MM-105

The Incompetent Cervix*

THE INCOMPETENT cervix is now a recognized entity responsible for second-trimester cervical effacement and dilatation, resulting in pregnancy loss due to low fetal salvage if untreated. The success of surgical procedures to correct the incompetent cervix and prevent second-trimester fetal loss associated with this condition is undeniable. Surgery has been employed on the external cervical os, midcervical region, or the internal cervical os as well as on all three simultaneously, with reports of success rates of 50 to 95%. Surgical correction has been advocated during pregnancy as a therapeutic measure and during the nonpregnant state as a prophylactic measure against recurrence in future pregnancies. Cerclage** can be accomplished at either time. Surgical reconstruction of the cervix is performed on the nonpregnant uterus.

Cerclage, during pregnancy, seems to be gaining in acceptance as the method of choice, although individual preferences exist.

The cause of cervical incompetence often is not clear. Structural changes, secondary to cervical trauma, may be a factor in some cases; or the structure of the cervix may be congenitally abnormal, resulting in primary cervical incompetence. Where no structural defect is apparent, some physicians believe that a physiologic or dysfunctional type of cervical incompetence, based on anatomic or hormonal relationships, exists. In some cases the cervix may be normal by all known criteria; yet a grossly abnormal cervix often maintains a pregnancy without difficulty. Herein exists a threat to accurate selection of patients for treatment, resulting in differences of reported incidence and cures. Unfortunately, definitive diagnosis of cervical incompetence often escapes accurate measurement in the nonpregnant uterus. Cervical-balloon studies, catheter-traction techniques, examination with Hegar dilators, and cervicohysterography have been employed with variable reports of success, but all methods leave something to be desired in demonstrating cervical incompetence. During pregnancy the diagnosis is more objective and is determined by the observation of progressive, painless, cervical effacement and dilatation. Symptomatology contributes little; however, a history of previous midtrimester pregnancy loss should alert the physician to the possibility of cervical incompetence. Diagnosis during pregnancy requires immediate treatment, preferably surgical. Various transvaginal surgical techniques to effect closure of the cervix may be used, or a purse-string type of constriction may be produced at the internal os level by cerclage with fascia, silk, Merseline, Teflon, or other polyester fiber strips. Treatment can also be accomplished transabdominally if the cervix does not seem suitable for transvaginal techniques. Preference for vaginal or abdominal delivery varies, although most surgeons select abdominal delivery. If nonabsorbable material is used for cerclage, this must be cut or removed prior to vaginal de-

BE A MYTH-MONGER #3

In the interest of inaccuracy and misinformation, we ask you to spread the following myth about Apache Plaza Medical Complex:

APACHE PLAZA MEDICAL COMPLEX IS ON THE NORTHEAST EDGE OF MINNEAPOLIS. EVERYBODY KNOWS THAT PEOPLE IN THAT AREA ARE POOR CREDIT RISKS.

Apache Plaza merchants don't think so. As a matter of fact, northeast Minneapolis is one of the finest credit areas in the nation. Account delinquency at Apache Plaza is less than 2 per cent—a fantastically low rate.

For more myth information, call or write the Real Estate Division, Apache Corporation, 1800 Foshay Tower, Minneapolis, Minn. 55402. Telephone: (612) 339-7781.

APACHE PLAZA MEDICAL COMPLEX

Stinson Boulevard at 40th Ave., N.E.
St. Anthony Village, Minnesota 55421

BE A MYTH-MONGER #4

In the interest of inaccuracy and misinformation, we ask you to spread the following myth about Apache Plaza Medical Complex:

DOCTORS!! APACHE PLAZA'S MEDICAL COMPLEX DOES NOT HAVE A HOSPITAL NEXT TO IT.

True enough, it doesn't. The closest hospitals to Apache Plaza Medical Complex are from 9 to 15 minutes away. But then again, we must remember . . . over 95 per cent of a doctor's patients do not require hospitalization. By relocating adjacent to a hospital, you might put a geographic imposition on your patients, as well as your previous hospital commitments.
Doctor . . . as a matter of fact, Apache Plaza is the center of the community for all of northwest St. Paul, northeast Minneapolis, and suburbs.

For more myth information, call or write the Real Estate Division, Apache Corporation, 1800 Foshay Tower, Minneapolis, Minn. 55402. Telephone: (612) 339-7781.

APACHE PLAZA MEDICAL COMPLEX

Stinson Boulevard at 40th Ave., N.E.
St. Anthony Village, Minnesota 55421

livery. Rupture of the uterus has been reported when labor occurred and this was not done. A few patients have been successfully treated by prolonged rest in bed, beginning about the sixteenth week of pregnancy. This is almost impossible outside of the hospital, and the cost is formidable to the patient, with little hope of achieving a successful outcome. Endocrine therapy seems to be of little or no value in treatment.

True cervical incompetence is a relatively rare condition, occurring in 1:300 to 1:600 obstetric cases. A large obstetric service is needed to collect an appreciable number of patients if strict diagnostic criteria are observed. Surgery on patients with only a history of first trimester fetal loss is ill advised. From the standpoint of prevention, cautious and minimal dilatation of the cervix during curettage is recommended, and avoidance of rapid fetal extraction or difficult forceps delivery would seem indicated.

Carl E. Johnson, M.D.
Rochester, Minnesota

Auto-Immune Hemolytic Anemia

AUTO-IMMUNE HEMOLYTIC anemia (AIHA) appears to be an indisputable violation of Ehrlich's dictum of "horror autotoxicus." Yunis and Bridges in their article appearing in the May issue* have cited evidence that clearly shows many patients with the warm antibody type of AIHA have antibodies with Rh-Hr specificity. Detailed serologic studies often show these antibodies to react with blood group antigens inherited by the patient under study. Another group of patients with AIHA, the cold antibody type, generally have a favorable prognosis. Their antibodies show specificity for the i-antigen, a blood-group determinant found on their erythrocytes and the erythrocytes of most humans.

Leddy and Bakemier[1] have studied the structural characteristics of IγG globulins eluted from the erythrocytes of patients with the warm antibody type AIHA. Twelve of twenty patients showed monotypic reactions and eight bytypic reactions when tested with type K and L antisera. The occurrence of Coombs-positive** hemolytic anemia associated with thymic lesions in NZB mice has provided an experimental model to study other aspects of AIHA.

Other observations have cast more than reasonable doubt on the auto-immune etiology of this anemia. Zuelzer[2] has isolated cytomegalic virus from children with warm antibody type AIHA. Anti-i has been found in the serum of patients with infectious mononucleosis in cases with and without hemolytic anemia. Hillman and Giblett[3] have shown a change in the amount of i-antigen on the red cell that seems to be related to a decreased bone-marrow maturation time, and it has been shown that the i-antigen content of erythrocytes can be altered after incubation with mycoplasma species.

Whether AIHA is a disease of autoimmune origin or is secondary to some infectious agent will perhaps be answered with time. The practical problems of therapy for these patients, however, must be faced now. Steroids, immunosuppressive drugs, splenectomy, and even thymectomy have their advocates. Regardless of the basic therapeutic modality employed, both the pathologist and the clinician are presented with a dilemma when transfusions are considered to alleviate the anemia in patients with AIHA. The former, as pointed out by Yunis and Bridges, must make a negative choice, i.e., the least incompatible blood; the latter must contend with a less than expected response, or even a deterioration of the patient after transfusion.

To aid the pathologist in his search for the least incompatible blood, the clinician must allow adequate time for a thorough serologic investigation. In-vivo compatibility tests with Cr^{51}-labelled red cells may help in this quest. In some instances, plasmapheresis and autotransfusion may be the answer to the compatibility problem. A reduction in the patient's blood volume and an increase in his

Winthrop announces new

WinGel®

ANTACID TABLETS AND LIQUID

For peptic ulcer, gastric hyperacidity, gastritis

Each WinGel tablet or teaspoon (5 ml.) contains 410 mg. of combined, highly reactive, short polymer, aluminum and magnesium hydroxides **stabilized with hexitol.**

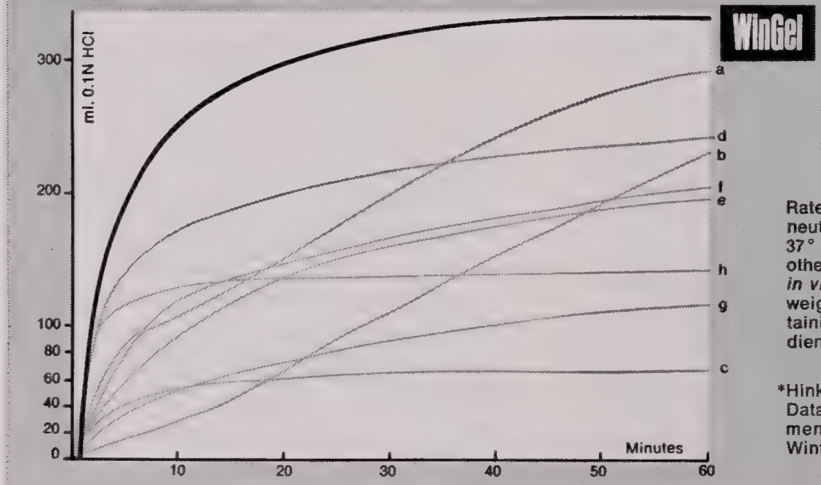
Neutralizes 300 times its active-ingredient weight in gastric acid for fast, long-lasting relief

Gastric or duodenal ulcer, acute or chronic gastritis, gastric hyperacidity...wherever there is "acid overflow" new WinGel can provide faster, longer, more complete neutralization.

In recent laboratory comparisons* with eight other leading antacids, new WinGel tablets not only neutralized more hydrochloric acid per active-ingredient weight, but neutralized it faster and longer than all other antacids tested.

Pleasant pink in color, WinGel is delicately mint flavored with a smooth-as-cream texture—qualities sure to please the patient on long-term therapy. New WinGel is also specially formulated to avoid constipation or diarrhea.

New WinGel neutralizes 300 times its active-ingredient weight in 0.1N hydrochloric acid—neutralizes more acid faster than other leading antacids



Rate of 0.1N hydrochloric acid neutralization at pH 3.5 and 37° with WinGel and eight other leading antacid tablets—*in vitro*. Samples equaled the weight of tablet material containing 1.0 Gm. active ingredients.*

*Hinkel, E. T., Jr. (New York): Data in the files of the Department of Medical Research, Winthrop Laboratories.

Dosage: Peptic ulcer or gastritis—from 2 to 4 teaspoons of WinGel liquid or 2 to 4 tablets chewed or allowed to dissolve in the mouth every two to four hours. **Gastric hyperacidity**—2 tablets or teaspoons about ½ to one hour after meals as needed; children from 7 to 14 years of age, 1 or 2 tablets or 1 or 2 teaspoons of liquid as needed.

How Supplied: Liquid in bottles of 8 fl. oz. and 1 pint. **Tablets** in cellophane strips, boxes of 50 and 100. (One teaspoon of WinGel liquid is equivalent to one WinGel tablet in acid-combining capacity.) WinGel, trademark reg. U.S. Pat. Off.

Winthrop Laboratories, New York, N.Y. 10016 Winthrop

Finally — a taste your patients will truly like

(1058M)

red-cell volume without the risk of sensitization to additional red-cell antigens can be accomplished.

In some cases, in spite of bed rest, supportive therapy, etc., heart failure and/or anoxia may make transfusion imperative. In these individuals packed red cells are the therapy of choice. These should be administered cautiously and the patient carefully observed during and following the transfusions for a possible reaction.

To help dispel the symptoms
of mild depressive states

CONSIDER **DEXAMYL®** FIRST
brand of dextroamphetamine sulfate and amobarbital

Often within the hour, 'Dexamyl' works to help dispel such symptoms as apathy, pessimism, loss of interest and initiative, and lack of ability to concentrate.

Formulas: Each 'Dexamyl' Spansule® capsule (brand of sustained release capsule) No. 1 contains 10 mg. of Dexedrine® (brand of dextroamphetamine sulfate) and 1 gr. of amobarbital, derivative of barbituric acid [Warning, may be habit forming]. Each 'Dexamyl' *Spansule* capsule No. 2 contains 15 mg. of Dexedrine (brand of dextroamphetamine sulfate) and 1½ gr. of amobarbital [Warning, may be habit forming].

The following is a brief precautionary statement. Before prescribing, the physician should be familiar with the complete prescribing information in SK&F literature or *PDR*.

Precautions: Use with caution in patients hypersensitive to sympathomimetics or barbiturates and in coronary or cardiovascular disease or severe hypertension. Do not use in patients taking MAO inhibitors. Excessive use of the amphetamines by unstable individuals may result in a psychological dependence; in these instances, withdraw the medication. Use cautiously in pregnant patients, especially in the first trimester. *Side effects:* Insomnia, excitability and increased motor activity are infrequent and ordinarily mild.

SK&F SMITH KLINE & FRENCH LABORATORIES

You May Be Right

The concluding statement in my editorial regarding The Scimitar Syndrome should have been as follows.

"A more painstaking search of the literature to include for example the paper entitled The Scimitar Syndrome by Sanger et al, Archives of Surgery, Volume 86, page 84, 1963; a report of five cases undergoing surgery would have further embellished the report of this surgical achievement."

Joseph J. Garamella, M.D.
Minneapolis, Minnesota

I Thought the Government Was Fighting Rebates

I have recently read for the first time that some of the drug houses are giving special prices, or rebates, to hospitals for Medicare and welfare patients. If drug houses can reduce their prices in this way, must they not be charging too much in the first place, and possibly could they not reduce prices of all drugs? The individual who pays his way may in some instances have limited resources, and such individuals are probably more deserving of lower prices than those who are being cared for by the government.

It has been indicated that this benefit can apply to any of the 19,000,000 persons over age 65 who are eligible for Part A of Medicare. Robert J. Meyers, Chief Actuary of the Social Security Administration, has estimated that if all drug companies were to make the same 25% reimbursement the government could save perhaps 3 to 4 percent of Medicare hospital costs. Is it possible that the government is interested in saving 3 or 4 percent on anything?

Perhaps there are others who have some feeling about this rebate from many of the reputable pharmacal laboratories.

Harry B. Neel, M.D.
Albert Lea, Minnesota

Dietitians, Education, and the Future

Dietitians are full partners in the business of taking care of diabetic patients and might well be partners in the other fields of medicine. As we finish our schooling and take stock of the situations available to us, we find that our vocation presents a much greater variety of opportunities than we had anticipated.

In the field of dietetics this may include among other things work in institutions, commercial food-processing concerns, public health, and nutritional research, as well as in the usual field of hospital dietetics. Each of these varieties of work requires different talents, and these talents are not measured necessarily by our grades in school. In institutional work an ability for organization and management may determine one's success,

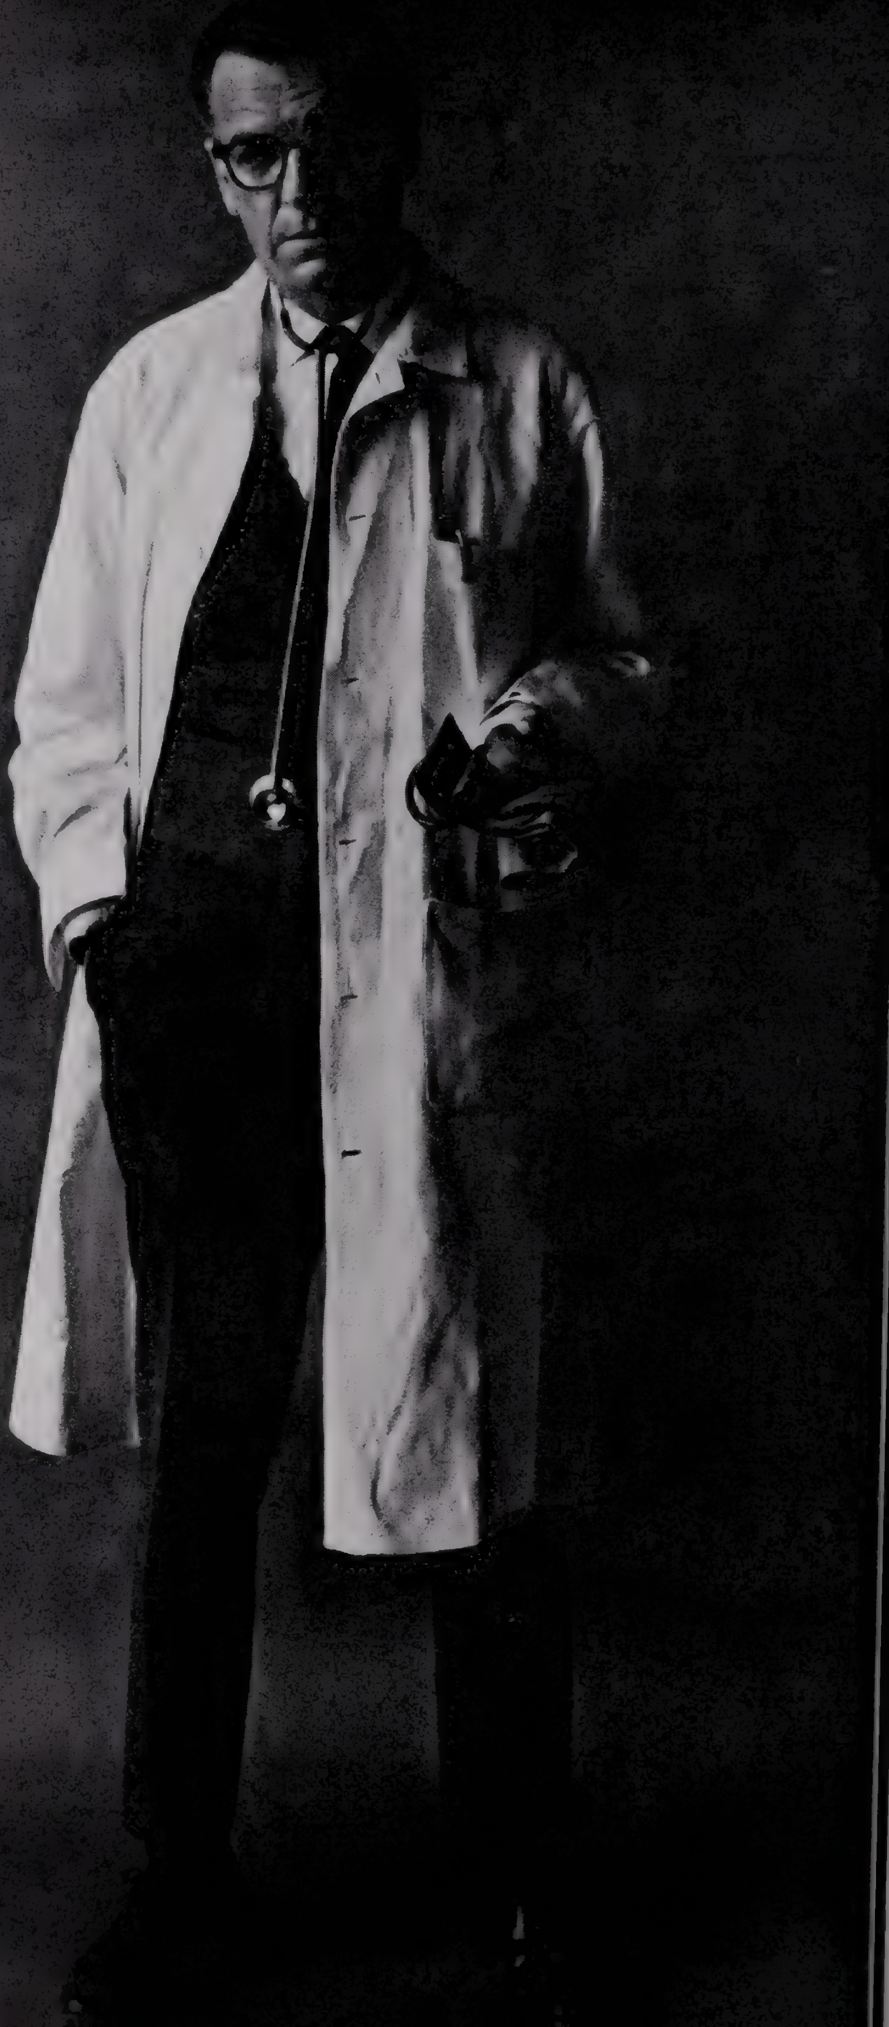
Frankly, most antihypertensives are pretty good if you give an adequate dose. I'm looking for one with a simple regimen so that mix-ups in doses and therefore the chance of side effects are minimized.



Regroton®

chlorthalidone 50 mg. reserpine 0.25 mg.

1 tablet daily brings pressure down

Advantage: Both components of Regroton are long-acting.
Average dosage: One tablet daily with breakfast.
Contraindications: History of mental depression, hypersensitivity, and most cases of severe renal or hepatic diseases.
Warning: Discontinue 2 weeks before general anesthesia, 1 week before electroshock therapy, and if depression or peptic ulcer occurs. With administration of enteric-coated potassium supplements, the possibility of small bowel lesions should be kept in mind.
Precautions: Reduce dosage of concomitant antihypertensive agents by one-half. Discontinue if the BUN rises or liver dysfunction is aggravated. Electrolyte imbalance and potassium depletion may occur; take particular care in cirrhosis or severe ischemic heart disease and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended. Use with caution in patients with ulcerative colitis, gallstones, or bronchial asthma.
Side effects: Nausea, vomiting, diarrhea, muscle cramps, headaches and dizziness. Potential side effects include angina pectoris, anxiety, depression, drowsiness, hyperglycemia, hyperuricemia, lassitude, leukopenia, nasal stuffiness, nightmare, purpura, urticaria, and weakness.
For full details, see the complete prescribing information.
Availability: Bottles of 100 and 1000 tablets.

Geigy

but such an ability probably did not help in getting a good grade in biochemistry. Warmth of personality is not measured by grades in mathematics or psychology.

As the field of dietetics and nutrition advances, the individual dietitian will need to keep abreast of developments or gradually become obsolescent.

One may say that the obvious answer to the problem is the assiduous reading of several professional journals and regular attendance at the annual meetings of the professional societies. Such measures surely are desirable and necessary, but they may not be adequate. The answer proposed for this dilemma is continuing education. Such studying cannot be done by casually picking up bits of information from journals. It necessitates an organized, methodical review of the subject. If we do not develop and apply programs of continuing education, we will face the penalty of obsolescence, an occupational junkyard.

A good preparation in mathematics, chemistry, and physiology during one's undergraduate years gives one the best chance for staying abreast of technical advances.

Perhaps the most challenging medical problem we have today is atherosclerosis, and there is much to suggest that it is primarily a complex nutritional problem with additional factors of hereditary susceptibility and exercises. In certain diseases such as peptic ulcer and diabetes, in which dietary therapy is primary, many of our dietary rules for these diseases are impairing and have little factual basis. Some diseases are not ordinarily thought of as nutritional, but the optimal treatment for them may require new dietetic approaches. Examples of these might be hyperthyroidism and collagen diseases. Our changing industrial environment, with the chance of accumulation of traces of various elements or toxic organic substances, may permit emergence of yet unrecognized syndromes with nutritional components.

Finding sources of protein for an over-populated world is a problem. Protein can be derived from mass-processed whole fish or leaves, but the political, economic, and dietetic problems of utilizing such sources have not yet been solved. The physician, the biochemist, and the physiologist will be concerned about nutritional problems, and the person who leads the way may carry any of these labels and will need the cooperation of someone in each of the other fields. The dietitian, if she is qualified, may well find herself playing an increasingly important role. In order to provide dietitians for the future we will need to recruit undergraduate students with first-rate abilities in chemistry, mathematics, and the physiologic sciences. We will not be able to describe the particulars of her future job. We can be sure, however, that it will be challenging.

SQUIBB NOTES ON THERAPY

Breast-feeding and the "modern mother"

Despite a mild resurgence of interest in the importance of breast-feeding a few years ago, many women today do not choose to nurse their young. This is for a variety of reasons—social, economic, cultural and sometimes medical. In such cases the physician's task is to find the most suitable means of preventing lactation and easing the pain of breast engorgement.

The means of therapy

The value of hormone therapy for this indication is of course well established. Both androgen and estrogen are known to inhibit the production and secretion of the lactogenic hormone by the anterior pituitary. As estrogen levels decline sharply at parturition, lactogenesis is established. When androgen and estrogen are administered to the patient before the release of the lactogenic hormone lactation and breast engorgement are usually prevented.

The time of therapy

The time of administration of this combined medication is crucial; it must be given early enough to suppress the pituitary prolactin and last long enough to permit physiologic readjustment during the puerperium. Excellent results are most often seen when therapy is administered before the onset of the second stage of labor.

However, factors other than effectiveness must also be considered. The agent selected should not interfere in any way with parturition, subsequent uterine involution and the restoration of normal ovarian cyclic function. Furthermore, it should not cause rebound breast engorgement or other manifestations of hormonal imbalance.

A balanced formulation

Providing single-dose therapy for the prevention of lactation and breast engorgement, Deladumone OB is a potent androgen-estrogen combination with a prolonged action. The optimal balance of androgenic and estrogenic hormones achieved in this preparation minimizes the disadvantages inherent in single hormone therapy, such as rebound breast engorgement. Involution of the uterus and resumption of menstrual cycles are not affected.

As reported in a recent published study (Roser, D. M.: Obstet. & Gynec. *27*:73, 1966), Deladumone OB provided good suppression of breast engorgement in 95.3% and suppression of lactation in 81.1% of 86 obstetrical patients. These results are in general agreement with those of many earlier investigations; in several studies this injectable androgen-estrogen combination proved to be superior to oral medication.

Dosage:

As a single injection of 2 cc. before the onset of the second stage of labor.

Contraindications:

Established or suspected mammary cancer or genital malignancy.

Precautions and Side Effects:

Certain patients may be unusually responsive to either estrogenic or androgenic therapy. In such individuals virilization, uterine bleeding or mastodynia may occur.

Supply:

Deladumone OB, providing 180 mg. testosterone enanthate and 8 mg. estradiol valerate per cc., is available in 2 cc. Unimatic® disposable syringes and in 2 cc. vials. Both preparations are dissolved in sesame oil, with 2% benzyl alcohol as a preservative. *Before use, consult product literature for full prescribing information.*

Deladumone® OB

Squibb Testosterone Enanthate (180 mg./cc.)
and Estradiol Valerate (8 mg./cc.)
Single-dose injection for lactation inhibition

SQUIBB *'The Priceless Ingredient' of every product is the honor and integrity of its maker.*

The Ailing Pioneer
His Ague

"Don't go to Michigan, that land of ills;
The word means ague, fever and chills."

Although the miseries that plagued the Midwest pioneer could hardly match the tribulations of a Job, they were indeed considerable. Whereas Job had boils, the pioneer had the ague. In fact, ague was so common that it was hardly regarded as a disease — but rather as an endemic feature of frontier life.

Its etiology was never definitely determined: most of the natives blamed the fickle climate and the miasmatic soil, cavalierly ignoring deficient diet and lack of sanitation. Historian James Hall, however, claimed that excessive consumption of meat and alcohol was responsible for the ague; the Medical Repository commented: "The inhabitants are almost constantly in a state of repletion, by stuffing and cramming, and by the use of stimulating drink;"* and Dr. Daniel Drake went so far as to point out the danger of spontaneous combustion in the human body from the ingestion of too much animal fat and spirituous liquor: "As a general fact, the people of the Valley (Mississippi) eat too much. The bodies of corpulent inebriates, when asleep, have, in several instances, taken fire, by the accidental contact of a burning coal or candle, and all the soft parts have been reduced to ashes, or driven off in clouds of thick smoke. To conceive of the possibility of this revolting catastrophe, we need only recollect the combustible nature of fat, and the still more inflammable quality of ardent spirits."*

Nomenclature-minded physicians classified the types of ague. Dr. William Daily's categories included Continued, Remitting, and Intermitting — with the paroxysms differentiated into Quotidian (morning-occurring), Tertian (noon-occurring), and Quartan (afternoon-occurring) not to mention such further confounding reductions as Simple and Double, Anticipated and Postponed.

Ague victims shook! Sometimes so hard as to rattle the dishes on the shelves! One family shivered so violently in unison that workmen shingling their roof were frightened off by the vibration. Babies were born quaking! Even the cattle were not immune but shuddered so vehemently that they had to lean against the fences for support.

For a vicarious fit of the ague the imaginative reader has only to peruse a partial description by one articulate victim:

"You felt as though you had gone through some sort of collision, thrashing-machine or jarring-machine, and came out not killed, but next thing to it. You felt weak, as though you had run too far after something, and then didn't catch it. Your back was out of fix, your head ached and your appetite crazy. Your eyes had too much white in them, your ears had too much roar in them, and your whole body and soul were entirely woebegone. You didn't think too much of yourself and didn't believe that other people did, either; and you didn't care. About this time, if you had the strength and means, you picked up Hannah and the baby, and your traps, and went back 'yander' to 'Old Virginny,' the 'Jerseys,' Maryland or 'Pennsylvany.' "*

A few pioneers did return whence they had come. But the hardiest stayed on.

when agitation

accompanies

spasm of the

'G. I.' tract.

Butadonna

BUTABARBITAL SODIUM 15 MG. [illegible]
[illegible] MAY BE HABIT FORMING
BELLADONNA EXTRACT [illegible]

provides gentle,

intermediate sedation and

relaxes 'G. I.' spasm.

Butadonna quiets the "brain-on-gut" influences by providing the smooth, intermediate sedative, butabarbital sodium, desirable in combination with the proven antispasmodic, belladonna extract. Butabarbital sodium is more rapidly eliminated than phenobarbital, and avoids the latter's cumulative effect.

Indications: Antispasmodic-sedative. Useful in the treatment of peptic ulcer, gastritis, duodenitis, irritable colon syndrome, ulcerative colitis, regional enteritis, and other conditions associated with gastrointestinal spasm. Also may be useful in functional dysmenorrhea.

Usual adult dosage is one tablet 3 or 4 times daily as needed.

Caution: Contraindicated in glaucoma and urinary retention. Reduce dosage or discontinue use in event of blurring of vision, dryness of mouth, tachycardia, or excessive drowsiness. Continued use of butabarbital sodium may be habit forming.

after surgery

B and C vitamins are therapy: Therapeutic amounts of B and C in stress formula vitamins often are vital during periods of physiologic stress. STRESSCAPS capsules, designed to meet increased metabolic demands, aid in achieving a more comfortable convalescence, a more rapid recovery. After surgery, as in many stress conditions, STRESSCAPS vitamins are therapy.

Stresscaps®
Stress Formula Vitamins Lederle

FOR PROFESSIONAL
RECOMMENDATION ONLY

Each capsule contains:

Vitamin B_1 (Thiamine Mononitrate)	10 mg
Vitamin B_2 (Riboflavin)	10 mg
Vitamin B_6 (Pyridoxine HCl)	2 mg
Vitamin B_{12} Crystalline	4 mcgm
Vitamin C (Ascorbic Acid)	300 mg
Niacinamide	100 mg
Calcium Pantothenate	20 mg

Recommended intake: Adults, 1 capsule daily, for the treatment of vitamin deficiencies. Supplied in decorative "reminder" jars of 30 and 100; bottles of 500.

Curbstone Consultation

Pulmonary Function Test

QUESTION: What is the best method of doing a pulmonary function test in the doctor's office without employing expensive equipment?

ANSWER: Vital capacity can be determined with a simple spyrometer or other available device. Though it is usually reduced during attacks, and especially when interim asthma continues, a normal or higher value does not rule out emphysema even of the destructive type.

When vital capacity returns to normal with relief from bronchial asthma, resulting from the control of inhalant and especially of food allergy, irreversible obstructive emphysema has not occurred.

A more accepted office test is the first second volume of forced expiration below 45% of the vital capacity. Franklin and Lowell favor determination of the E 50-75, which is the expiratory flow rate in the 3rd quarter of forced expiration, expressed in cc./second. Abnormal values are below 1300 cc. in patients over 40 years of age. In severe, obstructive emphysema the values often are between 300 and 700 cc.

When bronchial asthma, associated with reversible emphysema is relieved by control of inhalant and especially of chronic food allergy, these tests return to normal. When destructive emphysema has occurred, especially when an allergic or asthmatic predisposition is present, improvement in these tests may be slight or absent.

The good or excellent relief in symptoms in such destructive emphysema, usually with chronic bronchitis, which we reported at the meeting of the A.M.A. in June resulted from the control of inhalants and especially of food allergy, was not associated with corresponding improvement in these tests. This indicates that the benefit was due to the relief of bronchospasm, edema in the airways, and bronchorrhea arising from chronic allergy and not from a reduction in the destructive changes in the lungs. This relief continues with or without minimal oral or inhalant bronchodilators and corticoid therapy, providing the allergy, especially to foods, is rigidly controlled. These results challenge every physician to study and control food, and to a lesser extent inhalant allergy in all these cases with emphysema.

When offered a penny for their thoughts, few people are honest enough to admit they can't make change. — Mundy Smith

SQUIBB NOTES ON THERAPY

MOLECULAR REMODELING–

laboratory exercise or clinical necessity?

More than twenty-five years have passed since the discovery of the diuretic activity of sulfanilamide started pharmacologists on a succession of molecular remodelings to find the ideal diuretic.

Diuresis–a sought-after clinical effect from an unwanted side effect

It started in 1937 when a clinician reported that the administration of a sulfonamide was sometimes accompanied by an unexplainable side effect–metabolic acidosis.[1] Three years later the side effect was explained. The sulfonamide radical of sulfanilamide inhibited carbonic anhydrase,[2] the enzyme responsible for converting carbon dioxide and water to hydrogen ions and bicarbonate ions.

Later, other investigators showed by dog experiments that metabolic acidosis probably resulted when the inhibition of carbonic anhydrase upset the exchange of hydrogen and sodium ions, causing increased excretion of sodium as the bicarbonate.[3]

It was twelve long years after the first report of the unexplainable side effect (metabolic acidosis) that it was finally shown that large doses of sulfanilamide administered to edematous patients were indeed capable of promoting diuresis.[4] However, the possibility of toxic effects from its prolonged use and its relatively weak diuretic action made it impractical for clinical use as a diuretic.[5]

Because the inhibition of carbonic anhydrase seemed to be the key to effective diuresis, investigators began to look for more potent enzyme inhibitors —in the hopes that they would be more effective diuretics.

The most important of these early compounds, acetazolamide, enjoyed several years of fairly wide clinical use.

Its carbonic anhydrase inhibitory activity was several hundred times greater than that of sulfanilamide.[6] The increase in inhibitory activity, however, increased not only the excretion of sodium and bicarbonate ions, but also the excretion of potassium.[7] And, like its predecessor, acetazolamide precipitated mild acidosis. Its prolonged use could result in hypokalemic acidosis.[7]

The 'thiazides'–an answer to the metabolic acidosis caused by carbonic anhydrase inhibition

Despite the fact that the sulfonamide group appeared to be responsible for carbonic anhydrase inhibition which in turn appeared to be responsible for diuresis, investigators began to synthesize compounds with structural alterations to the sulfonamide group.

The first major breakthrough came with the synthesis of chlorothiazide. Altering the sulfonamide group did indeed alter the ability of chlorothiazide to inhibit carbonic anhydrase–it was only 1/10th as potent as acetazolamide in inhibiting the enzyme.[8] Despite the drop in inhibitory potency, however, chlorothiazide proved to be an effective diuretic–an observation that led to the conclusion that its diuretic action was due to some mechanism other than its action on carbonic anhydrase.[9, 10]

For effective diuresis, chlorothiazide was administered in daily dosages ranging from 250 to 2000 mg.[11] It increased the excretion of sodium and chloride; and, to a lesser extent, potassium and bicarbonate.[11] The excretion of potassium appeared to be maximal at higher dose levels at which, theoretically, the carbonic anhydrase inhibitory effect is more active.[11] Its prolonged use, therefore, could sometimes result in metabolic hypokalemic, hypochloremic alkalosis.[7]

Naturetin–effective diuresis with more favorable electrolyte balance

Other thiazides followed—with improvements being aimed at two particular areas: 1. attempts to increase diuretic action in relation to the milligram potency of the drug, and 2. attempts at a more favorable sodium/potassium ratio in the urine, i.e., to decrease the excretion of potassium while maintaining the excretion of sodium.[12]

One of these, Naturetin, Squibb Bendroflumethiazide, has made advances on both these points. "By adding a 3-benzyl radical to hydroflumethiazide a rather dramatic reduction in dose range is accomplished. With this drug, effective sodium excretion is obtained with doses between 2.5 and 10 mg., which is a 200 to 1 ratio as compared to chlorothiazide..."[13]

Moreover, due probably to its virtual lack of carbonic anhydrase inhibition, Naturetin (bendroflumethiazide) has been shown to cause less potassium and bicarbonate loss and less alteration in urinary pH than either chlorothiazide or hydrochlorothiazide.

Naturetin is outstandingly effective not only in establishing, but also in maintaining, excretion of retained fluid in edematous patients. And its duration of action is sufficiently prolonged to allow a single daily administration in most patients. Naturetin is also an effective antihypertensive agent.

Contraindications: Severe renal impairment; previous hypersensitivity.

Warning: Ulcerative small bowel lesions have occurred with potassium-containing thiazide preparations or with enteric-coated potassium salts supplementally. Stop medication if abdominal pain, distension, nausea, vomiting, or G.I. bleeding occur.

Precautions: The dosage of ganglionic blocking agents, veratrum, or hydralazine when used concomitantly must be reduced by at least 50% to avoid orthostatic hypotension. Electrolyte disturbances are possible in cirrhotic or digitalized patients.

Side Effects: Bendroflumethiazide may cause increases in serum uric acid, unmask diabetes, increase glycemia and glycosuria in diabetic patients and may cause hypochloremic alkalosis, hypokalemia; cramps, pruritus, paresthesias, and rashes may occur.

Supplied: Naturetin (Squibb Bendroflumethiazide) 5 mg. and 2.5 mg. tablets. Also available Naturetin c̄ K [Squibb Bendroflumethiazide (5 or 2.5 mg.) with Potassium Chloride (500 mg.)]. For full information, see Product Brief.

SQUIBB 'The Priceless Ingredient' of every product is the honor and integrity of its maker.

The Viewing Box

Metastatic Carcinoma to the Brain

A 60-YEAR-OLD white male was admitted to the University of Minnesota Hospitals with a chief complaint of severe right frontal and retro-orbital headaches of five weeks' duration. He had also noted intermittent blurring of vision and dizziness. Significant past history included a partial bladder resection two years earlier for carcinoma.

Physical examination revealed an emaciated individual with a slight left-sided hemiparesis. Reflexes were normal and symmetrical. Examination of the eyegrounds showed a minimal degree of papilledema. There was no evident visual field cut.

A right carotid angiogram was performed.

Roentgenographic Findings

The plain film examination of the skull was normal. The pineal gland was not calcified.

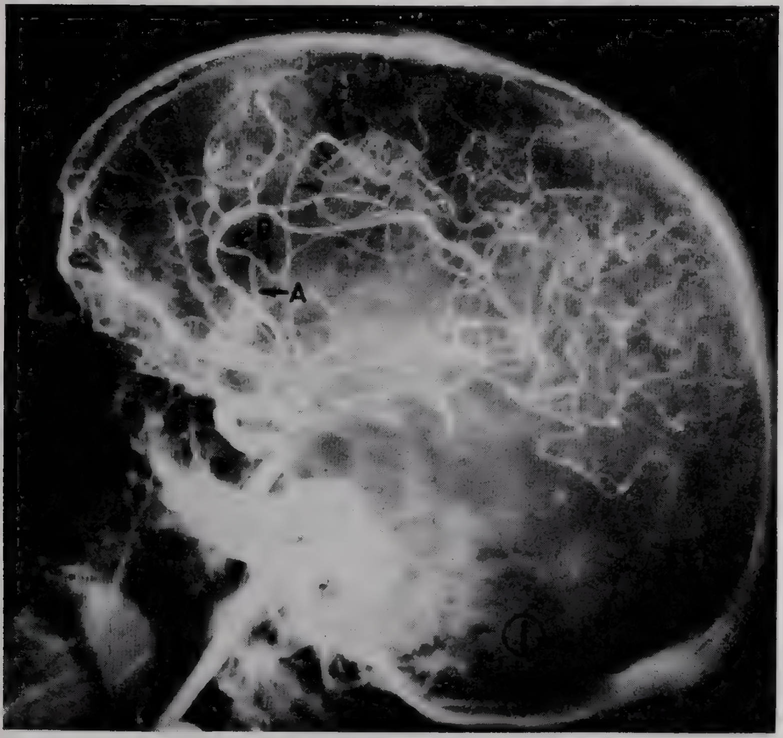

Figure 1

The initial film of the right carotid angiogram (Figure 1), made in the arterial phase of circulation, shows depression of the branches of the middle cerebral artery in the anterior portion of the Sylvian fissure. The ascending frontoparietal branch of the middle cerebral artery (labelled "A") divides into two main branches ("B"), each of which proceeds upward over the convexity of the frontal lobe and then ("C") gives off a number of terminal branches in an abnormal configuration (unlabelled arrows).

Continued

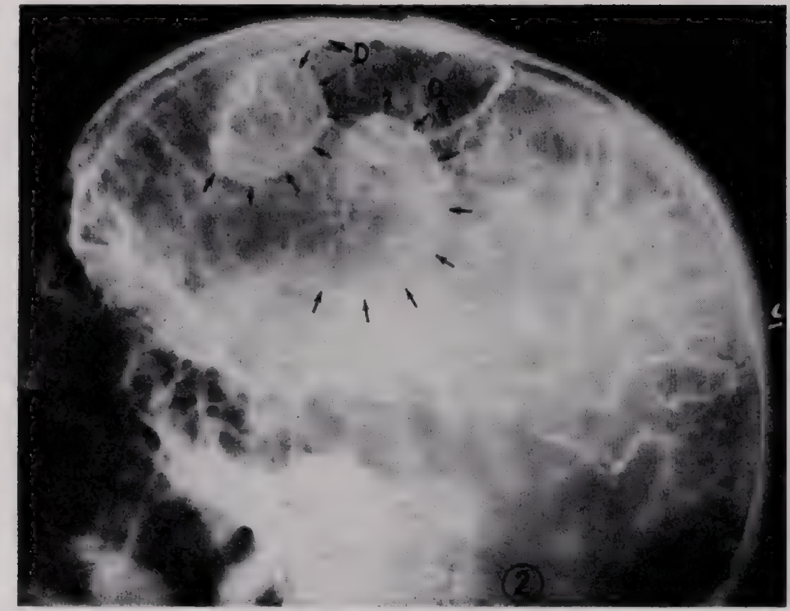

Figure 2

A film made later in the arterial phase (Figure 2) shows two well defined vascular masses (unlabelled arrows) in the same areas as the terminal branches described in Figure 1. The tiny vessels clustered mainly on the periphery of these masses drain into large veins ("D") which flow upward over the convexity of the frontal lobe to drain into the superior sagittal sinus. Note that the remainder of the brain is still in the arterial phase, emphasizing the rapid circulation of contrast medium through these masses.

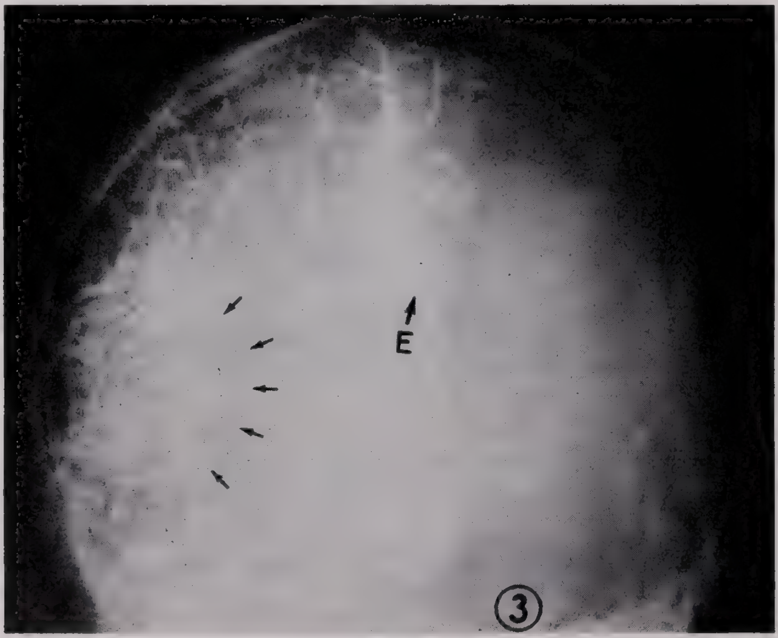

Figure 3

Figure 3, an anteroposterior projection, shows displacement of the anterior cerebral artery to the left of the midline. When the branches of this artery reach the falx, they abruptly return to the midline ("E"). The larger of the two vascular masses is outlined on its medial aspect by the line of unlabelled arrows.

DIAGNOSIS: METASTATIC CARCINOMA TO THE BRAIN.

Comment

About five per cent of all patients dying with malignant disease have cerebral metastases. These tumors comprise about twenty per cent of all neoplasms of the brain.[1] At time of diagnosis, either by angiography or at necropsy, they are usually multiple, although about thirty per cent of cases in reported series had only solitary metastases in the brain.

Small metastases are usually found near the junction of the cortex and the white matter of the brain, a point in common with emboli in general. This is likely due to the sudden transition from the vascular gray to the relatively avascular white matter. Since metastasis to the brain is commonly accepted to be via the arterial route, this abrupt transition in size and number of vessels would provide a logical stopping point for blood-borne emboli of tumor cells.

The most common source of cerebral metastases is the lung. Over one half of the patients in the large series reported by Russell and Rubinstein[1] and by Chason, Walker, and Landers[2] had their primary carcinoma in the lung. One rationale for this predominance is that these tumors, by invading and seeding into the pulmonary venous system, can bypass the filter of the lung, through which blood-borne cells from other tumors must pass before reaching the brain. Other fairly common sources of cerebral metastases include breast, kidney, and melanoma. The latter tumor, though rarer by far than cancer of the lung, kidney, or breast, shows a remarkable predilection to metastasize to the brain. A primary in the bladder, as in this case, is relatively rare.

The diagnosis of cerebral metastasis by angiography is not always an easy one.[3,4] Multiplicity of lesions, as in this patient, is perhaps the best sign. Metastases generally are well defined rounded masses with peripheral vascularity, usually situated in the terminal region of a given artery. They are often surrounded by extensive edema. Circulation through these usually highly vascular tumors is rapid with early venous filling, as seen above. The differentiation from a vascular astrocytoma or glioblastoma on the basis of angiography may be difficult, emphasizing the importance of demonstrating multiple tumors.

Treatment of these patients is generally palliative and usually includes the administration of systemic corticoids to reduce the accompanying cerebral edema.[5] Surgical removal of solitary lesions or external radiation therapy of the cerebrum in patients with angiographically demonstrated multiple lesions may be of some benefit.

Neuro-Pediatrics Conference

*Hyperactivity, Behavior Problems**

Minimal Organic Cerebral Dysfunction or Environmental Deficit?

THIS EIGHT-YEAR-OLD girl was first seen at the University Hospital on June 18, 1965, at the request of Dr. J. Havel because of school adjustment problems.

Dr. Ted Buselmeier**

Although the initial visit was precipitated by hyperactivity and lack of attentiveness in school it was soon apparent the patient has been somewhat of a problem at home since late infancy. The mother says the child has always been somewhat nervous, has had difficulty getting along with her sibs, and has difficulty forming friendship relationships with other children her age. She has been on Hydroxyzine hydrochloride (Atarax) 1-10 mg. tablet four times daily since early fall. The mother has noted no improvement with this treatment until the last two to three weeks coincident with a change to two tablets twice daily.

The child had frequent "colds," skin eruptions (apparently associated with ingestion of tomato), and uncomplicated measles at 3½ years. If not awakened she also wets the bed once during the night. Past history is otherwise unremarkable.

Examination revealed a pleasant but apprehensive blond girl with no significant physical deficits. She responded to some questions with an anxious "I forgot." Neurological examination revealed poor hand coordination, poor left-right discrimination, and number and letter reversal.

Many eosinophiles were noted on nasal smear; urinalysis revealed 1 plus albumin on one occasion (culture negative), and an electroencephalogram was interpreted as mildly abnormal because of some diffuse and localized slowing in the left mid and posterior temporal area.

---

*Sponsored by the U. S. Public Health Service Grant N2502A63. These conferences are an integral part of the Comprehensive Clinic Program at the University of Minnesota Hospitals. The pediatric conferences are held weekly from 1 to 2 p.m. every Wednesday. The adult conferences are held every Thursday at 4 p.m. Co-ordinators for the project are Dr. Edward C. Defoe and Dr. Charles Branthaver in Pediatrics and Dr. Robert Soll in Adult Neurology.

**Student physician, University of Minnesota Hospitals.

Continued

Dr. Bernard Lemieux*

I had the opportunity of seeing this child only once. Her head circumference was 57 cm., which is normal for a child of this weight and height. Her cranial nerves were intact and gross motor examination was normal with regard to strength and tonus. She is right-handed; however, when asked she is unable to discriminate between right and left. (Ability to so discriminate is usually developed at the age of six years.) As might be expected with a right-handed person, she was less well coordinated on the left than the right. Some choreiform movements of the fingers (particularly on the right) were demonstrable with the arms outstretched. Finger discrimination was performed less well on the left than on the right. Less use of the left arm was noted with running.

Moderate bilateral synkinesis or mirror movements were observed, which may have a developmental origin, if bilateral, or may be a manifestation of mild pyramidal hemisyndrome, if unilateral.

The history of immediate postnatal complications manifested by cyanotic spells and minor seizures and the above subtle neurological findings left me with an impression that she has a static minimal cerebral dysfunction of "organic nature manifest by a hyperkinetic behavior."

The minimal neurological findings may also be developmental in nature, which might be confirmed in a subsequent examination. A Bender or a WISC test often helps to substantiate this clinical impression.

A recent report notes abnormal slow wave frequencies as being the most consistent electroencephalographic changes in association with hyperkinesis in children. However, this tracing which showed mild diffuse and localized slowing in the left mid-posterior temporal area does not correlate well with the left-sided physical findings. All we can say about this particular electroencephalogram being specific is that the pattern is consistent with that which may be seen in hyperkinetic children of organic origin.

Dr. Edward Defoe**

What points do you use for differentiating a hyperkinetic syndrome secondary to minimal organic brain damage from the clinically similar one which relates primarily to a decrease in environmental input?

Dr. Lemieux

We perform all of the standard neurological tests including assessment of walking and running gait, fine coordination, recognition, etc. Usually the functionally hyperactive children perform well for their mental age. The child with organic disease is somewhat more clumsy, does not demonstrate bilateral coordination proficiency to the degree that he should, does not use one arm as much as usual with running, or has mild pyramidal findings. Environmental factors may be superimposed and, if so, act as uninhibited incoming sensory stimuli distressing the disorganized and immature brain, thereby contributing to the earlier appearance and the amplification of the hyperkinesis.

The hyperkinetic syndrome† should be considered under at least four different possible origins: developmental, environmental, psychiatric, and finally organic (see minimal cerebral dysfunction). Seen alone or in combination, those etiologies should as far as possible be dissociated, and no single cause should be disregarded to the detriment of any other.

Dr. Defoe

It is important for us to recognize that hyperkinesis is found in children with no evidence for organic dysfunction. It is equally important to recognize that the hyperkinesis found in the child with evidence for organic cerebral dysfunction is often only indirectly related. We have a tendency to treat initially with drugs and ignore other factors in the presence of definable organic disease. Yet it is obvious that the child with cognitive and coordination difficulties is the one in whom environmental input may be less than optimal. Careful investigation of environmental factors which may be etiologically significant is indicated regardless of the presence or absence of history or subtle neurological variation suggestive of organic disease.

Dr. Robert Havel*

The mother's pregnancy was uneventful. (However, she did have some problems with fatigue and with "blacking-out and fainting spells" for a time after the pregnancy.) Delivery was uneventful after an intravenous pitocin induction.

Difficulty with respiration and several spells of cyanosis and hypertonicity for the baby in the neonatal period were attributed (by a pediatric consultant) to airway obstruction from excess mucus. Following discharge from the hospital the infant did reasonably well. When seen at six weeks her weight was 9 lbs. 5 oz. and she was reported to be somewhat fussy. She was not seen again until 10 months of age, at which time she weighed 20 lbs. 4 oz. and was having no difficulty.

Aside from several brief visits for minor complaints the child was not seen again until March 1965, because of the school difficulties, nervousness and hyperactivity. At that time we found nothing remarkable on physical examination. Examination by an ophthalmologist was also unremarkable. An electroencephalogram was reported as unsatisfactory because of hyperactivity.

Mrs. Helen Tressel**

From the beginning this child was considered by her kindergarten teacher to be strange and difficult to understand. I think the children also thought she was a little odd. She had a difficult time in the first grade, particularly with other children, with whom she fought a good deal. In the second grade we were able to do a little more and at this time we noted she had difficulty getting words straight. When we tried using different colors for a word, she made some improvement. She was quite difficult to manage and to keep contented. She liked to roam and investigate. However, she did learn to read somewhat and doesn't appear significantly below class-room intelligence level. Miss Moore now has her in the third grade.

Miss Shirley Moore†

Although she seems to enjoy reading, her performance is below the

Continued

average in the group. She has considerable difficulty with arithmetic and demands my help even to the point of crying out across the room, "You have to help me." She does not seek help from other children. She works pretty well by herself when she knows what to do. If she fails to understand things she just falls apart. She is easily hurt by the other children and will cry and come to the teacher for reassurance and approval. However, she has improved a good deal since the beginning of the year. I understand the mother has changed the medication; this may be a big factor. Perhaps she knows that I accept her the way she is and that the children also accept her; so she may not be so frustrated.

Dr. Harold Ireton*

What do you think are the specific reasons for this change? How have you handled troublesome situations such as her hollering across the room?

Miss Moore

The children in the room pay little attention to this now. She receives a minimum of attention for negative behavior.

Mrs. Tressel

Last year she received a good deal of attention for negative behavior (fighting with another girl in the class). However, this year the two have been separated. I believe the grouping of the children this year has made a difference.

Miss Eleanor Brandtner**

I have observed change and improvement which seems to be due to understanding by the mother and to the fact that the teacher is not threatened by what she does. She is more relaxed not only because of the medication but also because of the feeling of security.

Dr. Defoe

I suspect you have put your finger on the real reason for improvement. Actually, as far as drugs are concerned, she has not had an increase in dosage but rather a change in time of administration. In addition there is little objective evidence that this particular drug (Hydroxyzine hydrochloride-Atarax) is useful in the treatment of hyperkinetic states. I do not believe we can attribute improvement to a change in the medication.

Mrs. Carolyn Mowery†

We have had an interrupted, unsteady kind of contact with this family since April, 1965. The mother who is in her eighth month of pregnancy has missed several visits because of illness and for other reasons. The father seems to have lost interest in coming, due in part at least to his father's illness and a peculiar dependent relationship which appears to exist between the patient's father and paternal grandfather. There are also problems with the fourteen-year-old and the ten-year-old boys. The teacher has pointed out that the latter is making "animal noises" to the extent that they are quite disturbing to the school. I am also impressed with the inconsistency of the parents' management of the chil-

dren. The mother is certainly a nervous type of person, primarily involved in the discipline responsibility.

Miss Maxine Boyd*

Although she enjoys coming and has no trouble sitting for an hour or so, this child has trouble sticking with things that are difficult for her. Anxiety and anger tend to make her forget. She has obvious need for gratification. She eats a good deal and always notices when anyone has candy or food. Although she doesn't ask directly she constantly tries to create situations which will permit her to participate directly in food consumption.

Mrs. Rachel Watt**

The oldest boy in the family is 15 years old and in the tenth grade. He was somewhat upset when the family moved to their present address three years ago.

The other boy is ten years old and in the fifth grade. The patient is eight years old and in the third grade. The youngest child is now two years old, and the mother is expecting the birth of their fifth child about December 17, 1965. The parents plan to stay permanently in their present home. It has four bedrooms, three up, one down; a living room, dining room, kitchen and full basement. Their financial situation is understandably tight. The mother would like to stay in the hospital longer than three days when the baby is born, but her husband has only three days vacation and there is no money to engage full or part-time help. They are preparing the older boys to be of as much help as possible.

The patient apparently is getting along well in her present neighborhood. There are plenty of children to play with, and the mother does not feel she has to be constantly supervising, as the child is now more reliable and obeys regulations as to play areas, crossing the street, etc. She still has some odd behavior activities, however, such as emptying all the ice-cube trays into an end table drawer and "wasping" up toilet paper into big balls. The mother is irritated by this; but the father gives the impression of almost tactile identification with his daughter's enjoyment in this.

Impression:

These parents have been coping in a rather blind and limited fashion with child-rearing responsibilities. Married when very young, they still have many unsatisfied ego needs, and both appear to be somewhat anxious and apprehensive. Added to this are the financial pressures and a fifth child expected about December 17. Both parents have responded well to family counseling at Lutheran Welfare and are able to use suggestions and guidelines effectively. This family is continuing with Lutheran Social Service and expressed much relief and satisfaction with the casework service they are receiving there.

Dr. Harold Ireton

Current and past psychological evaluations yield the picture of a child with reasonably average intellectual ability (verbal-abstract skills) but

Continued

with significant perceptual and perceptual-motor problems. Intelligence testing in March, 1965, with the Wechsler Intelligence Scale for children indicated a verbal I.Q. of 92, but with a performance I.Q. of only 83. This below-average performance I.Q. is consistent with her performance on other largely non-verbal tests, where she is somewhat inferior for her age. This pattern of findings is suggestive of some central nervous system involvement.

Problems seem to center on her management in classroom and home environments and her learning difficulties, especially as they are related to reading.

Generally, we assume that when a child enters first grade he will have certain "pre-academic" skills, such as paying attention, following simple directions, and sitting still for the periods of time necessary for concentration. Regarding peers, he will have learned to share, to take turns and to "cooperate" in a variety of ways. If certain of these skills have not been mastered, classroom operations will be chaotic; much "deviant" behavior will be demonstrated, and the child will be rejected by peers. While it is tempting to classify these children as emotionally disturbed, what they need most is training in the skills they lack. Such skills are best taught by the teacher — defining, for herself, what is necessary and acceptable behavior and what is deviant behavior and then rewarding appropriate behavior with praise and attention in order to reinforce it, while at the same time ignoring deviant behavior or punishing it where there is no reasonable alternative. Deviant "unacceptable" behavior is often persistent because it is inadvertantly strengthened through the teacher's attention via sympathy or punishment as well as by attention on the part of the peers.

Whenever such deviant behavior develops we are faced with the difficult but possible project of starting at the child's level and reinforcing simple adaptive skills to build an increasingly large adaptive repertoire while at the same time diminishing negative maladaptive behavior. Ultimately the child learns that sufficient attention can be obtained through the practice and performance of adaptive skills and that attention-seeking through deviant behavior is less necessary.

Mrs. Tressel

Would you approve of her being put in a small group such as we now have for special learning problems?

Dr. Ireton

These children tend to be disturbed by large classrooms, not because they have short attention spans but because they are distractible. Although she was perfectly cooperative and paid attention when I tested her, she might not have done this if something had been going on next door. If she functions well in a large regular classroom, fine; if not, a less distracting environment should be arranged.

Mrs. Judy Edmands*

Generally understanding and expression of language appeared to be adequate for her age level. Behavior was characterized by some inattentiveness and distractibility, and she seemed rather tense and uncomfortable.

---

*Speech Pathologist, University of Minnesota Hospitals.

Visual-Perceptual Development. There were no obvious perceptual deficits; figure-ground discrimination was excellent for her age level. However, in the other areas of visual-perceptual development she did not perform as well as might be expected considering her general intellectual level. Visual motor coordination form constancy (ability to recognize a circle as a circle no matter what the size, color, etc.) was her poorest area of performance. Ability to judge position in space and spatial relationship was also somewhat below her age level. It was my opinion that these performances could have been affected either by a developmental delay related to central nervous system immaturity or by anxiety.

Reading. No formal rating was done of grade-level reading ability. However, it was obvious that she did not read up to age or grade level.

Visual recognition of alphabet letters (both capital and small) presented no difficulty for her. However, analysis of phonic abilities revealed practically no ability to associate the phonetic sounds with a letter (either vowel or consonant) unless the phonetic sound was the same as the name of the letter.

Impressions and suggestions:

1. There were no obvious perceptual deficits, although development in areas of visual motor coordination form constancy and understanding of directional and spatial relationships seemed not as mature as might be expected.
2. Most obvious deficit in reading skill was lack of phonetic knowledge.
3. Any efforts at remedial reading help should be aimed at (a) a complete analysis of phonetic knowledge and a due and organized attack on that area of reading skill, and (b) a progressive program of activities designed to promote understanding of direction and positions in space and relationships of things in space.

The work should be done on a one-to-one (tutoring) basis if possible.

Dr. Defoe

In summary, this is an eight-year-old girl with a neonatal history of cyanotic spells and minor seizures, subtle neurologic deficits, and an abnormal electroencephalogram suggesting fairly definite (although of minimal intensity) organic brain dysfunction. This may contribute directly to the hyperkinetic behavior and adjustment problems which promoted the referral. However, there is evidence in the family and total environmental history which suggests certain environmental factors as major contributors to her hyperkinesia. It is unlikely the medication she is receiving is contributing significantly to her welfare other than through placebo effect. The recent progress noted in modification of her behavior is more likely attributable to the understanding approach taken within the school and the parental guidance obtained through Lutheran Welfare. It is logical she should be weaned from the drug over the next few months. Efforts in family support and counseling should be continued along with maintenance of a school environment which maximizes feedback for positive and minimizes feedback for negative behavior. Lutheran Welfare is making a significant contribution to the family from the standpoint of support and disciplinary guidance and

Continued

should continue to play the primary role here. All are in agreement that the present approach as outlined by the school is sound.

The parents have expressed enthusiasm for having Dr. Havel function as the professional who should offer total ongoing medical support and guidance. We are pleased to have him here today to contribute and carry away the content of the conference for interpretation to the parents. We will not plan to see the patient at the University Hospital again unless further consultation is deemed advisable by Dr. Havel.

Trends in Neurological Therapy

November 9-11, 1966

A continuation course in Trends in Neurological Therapy will be presented by the University of Minnesota from November 9 to 11, 1966, at the Nolte Center for Continuing Education. This course is designed to bring the practicing physician up to date on the newer diagnostic and therapeutic measures available for the evaluation of neurologic disorders. Particular attention will be directed towards the management of the patient who has had a stroke or a similar chronic neurologic disorder.

Guest speakers will be *Doctors Simon Horenstein,* Assistant Professor, Division of Neurology, Western Reserve University School of Medicine, Cleveland, Ohio; *M. Wright Van Allen,* Associate Professor, Department of Neurology, State University of Iowa College of Medicine, Iowa City, Iowa; and *Charles Van Buskirk,* Neurologist, York, Pennsylvania.

The course will be presented under the direction of *Doctors A. B. Baker,* Professor and Director, Division of Neurology; and *Robert W. Soll,* Instructor, Division of Neurology. The remainder of the faculty will include members of the faculties of the University of Minnesota Medical School and the Mayo Graduate School of Medicine. Tuition: $75.00. Approved A.A.G.P. hours: 20.

Contact: Department of Conferences and Institutes, Nolte Center for Continuing Education, University of Minnesota, Minneapolis, Minnesota 55455.

Medical Seminar

Thrombophlebitis and Embolic Phenomena in Pregnancy

Relationship to the Clotting Mechanism

Presented as a Seminar
Sponsored by
The Faculty of the Mayo Graduate School of Medicine

THROMBOEMBOLIC DISEASE in obstetric patients, with its possible serious consequences for both mother and baby, presents a challenge to the physician.

Ullery[1] has said, "Until recently little could be done for thrombosis except to observe with respect and humility the devastating effects of this disease." However, with the discovery of anticoagulant drugs and the aid of new laboratory methods as well as the advancement in surgical techniques, much progress has been made in the prevention and treatment of thromboembolism.

Virchow,[2] in 1856, pointed out that three things were important for intravascular clotting: (1) stasis of blood flow, (2) injury to the vascular endothelium, and (3) hypercoagulability (increased clotting tendency).

Since obstetric patients meet all these predisposing requirements, it is not surprising that thrombophlebitis is a fairly frequent complication of the pregnant state.

Current Concept of Blood Coagulation[3,4]

In the light of present knowledge, clotting can be considered to occur in four steps: phase 1, generation of thromboplastin; phase 2, activation of thromboplastin; phase 3, conversion of prothrombin to thrombin, and phase 4, conversion of fibrinogen to fibrin. A more detailed consideration of the various coagulation factors is necessary in order to understand the action of the anticoagulant drugs (Figure).

In the first phase, coagulation is initiated in the presence of calcium by the combined action of four prothromboplastic factors (Hageman, PTA, PTC, and AHG) with platelet material (a phospholipid) to form plasma thromboplastin.

In the second phase, the plasma thromboplastin is activated by accelerator factors, V and X. Most investigators consider the stable factor (VII) unnecessary for activation of plasma thromboplastin but necessary for activation of tissue thromboplastin.

Activated thromboplastin as well as calcium is required for the formation of thrombin from prothrombin that occurs in the third phase.

Coagulation mechanism. (From Kazmier, F. J., and Spittell, J. A., Jr.: Oral Anticoagulant Drugs. Heart Bull 14:64, 1965, with permission of the publisher, Medical Arts Publishing Foundation.)

Continued

Thrombin, even in trace amounts, finally converts soluble fibrinogen to the insoluble gel fibrin.

It has been said, "When the fact that blood is a suspension of particles in a liquid that contains all the necessary ingredients to change it from a liquid to a solid in a matter of several minutes is considered, one can not be anything but awed at the delicate balance that must exist to maintain its fluidity."[4]

In normal, well individuals there is a perfect balance of the involved factors which encourage or prevent the clotting of blood so that its fluid state is maintained; but in other individuals, because of changes in this mechanism, a hypercoagulable state is reached.[5]

The Relationship of Coagulation Factors and Pregnancy

Clotting Factors

Most investigators agree that certain coagulation factors increase in concentration as pregnancy progresses. Todd and associates[6] found, in 43 coagulation studies on 28 women at various stages of pregnancy, a marked increase in activity in factors VII and X and a moderate increase in concentration of fibrinogen.

Pechet and Alexander[7] reported that factor IX was also increased in pregnancy.

The higher the concentration of factors V, VII, or X, either individually or collectively, the shorter is the prothrombin time.[6] The increases in these clotting factors and the changes in fibrinogen, fibrinolysin, platelets, and phospholipids constitute a truly hypercoagulable state in a pregnant woman and provide an ominous setting for thromboembolism.[7]

It has been stated[8] that all the factors that require vitamin K for their synthesis and are depressed by coumarin compounds — namely, factors II (prothrombin), VII (stable factor), IX (plasma thromboplastin component), and X (Stuart-Prower factor) — are increased during pregnancy.

The clotting defect induced by coumarin and indandione is identical to that seen in vitamin K deficiency.[5] This suggests that oral anticoagulants and vitamin K are competitive. Also, vitamin K is used as an antidote for the oral anticoagulants and restores the prothrombin level to normal in three to six hours.[3]

In pregnancy, factors IX, X, VII, and II are increased.[6-8] These same factors are dependent on vitamin K for synthesis,[5] and these are the factors depressed by coumarin drugs.[5,9]

Quick Test

The one-stage prothrombin test of Quick measures the time required for a fibrin clot to form after the addition of thromboplastic material and calcium ions to oxalated plasma.[3] Normally, formation of the fibrin clot requires 12 to 19 seconds, the time depending on the thromboplastin used. If only calcium ions are added, 90 to 110 seconds are required for the clot to form.

The prothrombin test does not reflect any changes in the clotting activities of the first phase, including factor IX. However, other studies of the clotting factors affected by oral anticoagulants have shown that factor IX closely parallels factor VII. Therefore, because the one-stage prothrombin time accurately demonstrates changes in factor VII, it is believed that the Quick test continues to be a reliable test of anticoagulant effect.[3,4]

Other Predisposing Factors in Pregnancy

In addition to the increased clotting tendency in pregnancy, other circumstances predisposing to thromboembolic disease are those that produce stasis, such as prolonged rest in bed, immobility of the lower extremities, tight abdominal binders, pressure on the popliteal spaces from improperly fitted leg holders or stirrups, obesity, and varicose veins.[5] Other factors are anesthesia, infection, dehydration, nutritional deficiencies, anemia, and hemorrhage.[1,4]

In Ullery's[1] report of 172 cases of thromboembolic disease in the Pennsylvania Hospital, 77% had a hemoglobin value of 9.4 Gm. or less, thus emphasizing the importance of anemia as a predisposing cause. He also found that the hazard of venous thrombosis is increased after abdominal delivery or any difficult operative procedure such as version or midforceps. The incidence of venous thrombosis was also greater for patients who had had general anesthesia. Pulmonary embolism was diagnosed in 17% of the cases. None of the patients treated with anticoagulants died.

Management

It is Ullery's[1] opinion that elevation of the extremity, heat, and elastic bandages may be used in the treatment of postpartum venous thrombosis, but only in conjunction with anticoagulants or surgery.

Spittell[10] has stated the belief that superficial thrombosis may be treated without anticoagulants. However, if the thrombophlebitis becomes more extensive and progresses in spite of conservative treatment, anticoagulant therapy should be employed. For those with marked periphlebitic reactions, he recommends treatment with phenylbutazone.

Anticoagulants

The problem of using anticoagulant therapy in pregnancy is not one of value — since the value has already been proved in the nonpregnant state — but one of safety.[11]

In the early days of investigation into "spoiled sweet clover disease" of cattle, it was found that calves born of cows fed dicoumarin-containing fodder died of hemorrhage a few hours after birth. Thus, in cattle, the calf was more susceptible to dicoumarin poisoning than was the cow, and the hemorrhage-producing principle was capable of passing across the placental barrier.[12]

Wright[12] reported on nine pregnant patients whose venous thrombosis was treated with dicoumarin and in whom there was careful control of the prothrombin concentration at 30 to 40% of normal. A maximum of 18 days of anticoagulant therapy was adequate to relieve all the symptoms. There was only one infant death. In this case, the anticoagulant had been stopped 48 hours before labor began.

Epstein[13] reported three patients whose pregnancies were complicated by antepartum thrombophlebitis and pulmonary embolism and who were treated with coumarin drugs. In all three patients the pregnancies ended with intrauterine fetal death about five weeks after anticoagulant therapy was instituted.

It has been said that with the use of anticoagulants, the maternal mortality rate has been reduced. However, several authors have reported fetal hemorrhage and loss after such treatment.[5,14]

Aaro and associates[15] reported eight patients with antepartum thrombosis who were treated with anticoagulants for periods that varied from six days to 24 weeks. All eight patients were delivered of normal infants at term. The anticoagulant drug was stopped temporarily prior to labor, and vitamin K_1 was given to two patients to reduce further their prothrombin deficiency.

When oral anticoagulants such as the coumarin drugs are used, careful laboratory control is needed to steer the difficult course between ineffective dosage and a generalized hemorrhagic state. For this reason heparin alone is recommended in the antepartum period if one is not sure of the reliability of prothrombin determination or is not skilled in the use of the coumarin drugs.[11]

In the regulation of anticoagulant therapy, Nichol[16] has suggested a formula whereby the optimal therapeutic range of prothrombin deficiency is between 2 to 2½ times the normal prothrombin time in seconds. If the normal prothrombin time is 18 seconds, the optimal range is 27 to 45 seconds.[4]

In the series of Aaro and his associates[15] of 38 postpartum patients with deep venous thrombosis, all of whom were treated with anticoagulants, only one patient had significant postpartum vaginal bleeding. The prothrombin time of this patient was in normal therapeutic range (25% of normal). She was given vitamin K_1 as one of the therapeutic measures in order to help control her bleeding.

Of equal importance as an effective anticoagulant is heparin,[2,4] a mucopolysaccharide. Heparin acts immediately on contact with blood: (1) It forms an antithrombin that neutralizes thrombin and therefore inhibits the conversion of fibrinogen to fibrin; (2) it has an inhibitory action on the earlier stages of clotting; (3) it prevents the

Continued

agglutination of platelets; and (4) it carries a strong, negative electric charge which may be protective against thrombosis. Its anticoagulant effect is based on interference with the function of the coagulation factors rather than a depression of their concentration. Because of its higher molecular weight, heparin probably does not cross the placental barrier. Heparin must be given parenterally and its duration of action is short. At the Mayo Clinic it is given intravenously every four hours and is mainly used in the initiation of anticoagulant therapy or in short-term anticoagulant treatment. Its effect is measured by the whole-blood coagulation time. Protamine sulfate is used as an antidote to bring the coagulation time to normal.

Dextran

Recently, there have been reports of the use of dextran of high molecular weight (75,000) in order to prevent clot formation. Studies at the University of Maryland[17] have shown that dextran is very effective if used in the early stages of the disease but that it is much less satisfactory if the thrombophlebitis has been present for more than 48 hours.

In one report,[17] 39 patients with acute thrombophlebitis were given dextran. Thirty-five had dramatic improvement of symptoms within 24 hours, after which time they could walk without discomfort.

Sawyer and associates[17] suggested that infusion of dextran into the circulation causes physical changes in the blood and vascular system that prevent thrombus propagation and may hasten thrombus resolution. The amounts of dextran used do not result in any bleeding tendencies; so it is not necessary for clotting times to be measured or other laboratory procedures to be made on patients receiving dextran. Only a single administration in 24 hours is required.

Fibrinolytic Agents

The primary function of fibrinolytic agents is to promote the rapid dissolution of an intravascular thrombus.[18] However, the clinical trials of this form of treatment so far have been disappointing. There is also some toxicity shown in the form of mild-to-severe febrile response,[19] along with chills, nausea, vomiting, and hypotension. These fibrinolytic agents have not yet found a place in routine management.[4,19]

Thrombophlebitis

According to Mahorner,[20] venous thrombosis can be classified functionally into three groups: (1) superficial (involving the great and small saphenous veins); (2) deep — this type is potentially lethal — (involving the sural, popliteal and femoral, and ileofemoral veins); and (3) pelvic (in puerperal sepsis).

Superficial Thrombophlebitis

The characteristic appearance[10] is a red, painful, tender, nodular, or linear area. The thrombosed vein can be felt as a raised cord.[4]

In his discussion following the paper by Sawyer and associates,[21] Lilly suggested immediate surgical treatment for this condition. He stated that proximal interruption of the superficial vein should be done as an emergency procedure. This would prevent the development of a propagating thrombus; such a thrombus has occurred in a small percentage of cases.[22] Interruption[21] at the junction between the saphenous and femoral veins can be done under local anesthesia in a few minutes. The patient has a three-hour hospital stay and can return to work the next day.

Sawyer and his associates[21] have noted that patients who have had thrombophlebitis are prone to recurrence and have suggested that a single episode of superficial phlebitis in a leg is a reasonable indication for surgical excision of the involved saphenous veins.

Deep Thrombophlebitis[4,10]

Sural Veins. — Thrombophlebitis that involves the veins of the calf muscles is characterized by pain and tenderness and slight enlargement of the calf. Homan's sign (discomfort on forced dorsiflexion of foot) is positive. From his phlebography investigations, Bauer[23] concluded that 98% of the thrombosis of deep veins begins in the veins of the calf.

Popliteal and Femoral Veins. — Thrombophlebitis of these veins is usually an extension of sural thrombophlebitis, and the findings are similar, along with increased edema and tenderness on palpation of the popliteal space and frequently over the distal portion of Hunter's canal. The leg below the knee is enlarged, and the superficial veins are prominent.

Iliofemoral Veins. — In thrombophlebitis of these veins there is moderately severe pain in the thigh and groin and throughout the entire leg. The superficial veins are distended; the entire leg is enlarged, and the skin may be slightly cyanotic.[4,10,14]

When iliofemoral thrombophlebitis occurs in the postpartum state, this is the familiar "milk leg" or phlegmasia alba dolens.[24] Mahorner[20] stated the belief that when this is diagnosed, prompt operation is indicated, with incision of the femoral vein, removal of the clot, and restoration of the venous flow. Heparin is given intravenously. There is a dramatic relief of symptoms, and good results have been reported. However, McCallister and co-workers[25] evaluated the results of medical therapy in 132 patients with ileofemoral thrombophlebitis who were seen at the Mayo Clinic from 1950 through 1959. This medical treatment consisted of rest in bed, administration of anticoagulants, elevation of leg, warm stupes, and elastic supports. The comparison of the reported results of the treatment with thrombectomy indicates that the incidence of thrombophlebitic sequelae is similar whether patients are treated conservatively or with thrombectomy.

Other surgical procedures used for the purpose of preventing pulmonary emboli are ligation of femoral vein, ligation of the vena cava, and plication of the vena cava.[26,27] However, these are major procedures — often with unfortunate sequelae such as incapacitating venous insufficiency, edema, and leg pains — and they are reserved for instances when more conservative measures have failed.

Pelvic Thrombophlebitis

Collins and associates[28] have reported good results from ligation of the vena cava in women with pelvic venous thrombosis associated with puerperal sepsis.

Pulmonary Embolism

Although part of the treatment for deep venous thrombosis aims at preventing a pulmonary embolus, sometimes the first sign of thrombotic disease is pulmonary embolism.

In 100 autopsies involving dissections of the veins of the pelvis and lower extremities, McLachlin and Patterson[29] observed that, in every case in which a pulmonary embolus was found, a gross thrombus was demonstrated in the veins of the pelvis or lower extremities.

Depending on the size of the embolus, the clinical manifestation of pulmonary embolism may vary from slight pleuritic pain or hemoptysis with restlessness to sudden crushing pain beneath the sternum with dyspnea, cyanosis, and shock.

Wingate[30] wrote that pulmonary embolus is one of the first conditions to be considered in the differential diagnosis on the sudden onset of breathlessness in a pregnant or postpartum patient.

The treatment of pulmonary embolism should include the measures outlined for deep venous thrombosis. Oxygen is indicated for respiratory difficulty and atropine is helpful to relieve the bronchial spasm.[10]

Anticoagulant treatment is started with heparin and should be continued until the prothrombin time is within therapeutic range after therapy with oral anticoagulants has been instituted. Treatment with anticoagulants should be continued for several days after the patient is ambulatory.

Pulmonary embolectomy — the Trendelenburg operation — using the cardiopulmonary bypass is done occasionally.[17] Selection of patients for this operation depends on the accuracy and promptness of diagnosis and the availability of operative facilities and personnel for immediate operation. A ligation of the vena cava is done at the same time in order to prevent further emboli from forming.

Because of the serious consequences of thromboembolic disease, the best treatment of this disease is prophylactic.

Summary

Significant thrombophlebitis occurring

Continued

during and after pregnancy should be treated promptly with local heat, rest in bed, elevation of the extremity, and anticoagulants. Other methods of treatment such as use of dextran, thrombectomy, venous ligation, embolectomy, and fibrinolytic therapy are of limited or questionable value.

GREEN MEDICINALS*

Herbs for the Heart

Ecclesiasticus said: "The Lord hath created medicines out of the earth and a wise man will not abhor them."

For the heart, the blood, and its circulation herbalism prescribes daisy wine to be prepared as follows:

Daisy Wine

Over four quarts of daisies, picked off the stalks, pour one gallon of boiling water. Let it stand at night, then drain the liquid off and boil it for ten minutes. When it is lukewarm add one yeast cube, dissolved in a little warm water, two lemons and two oranges sliced, a cupful of raisins and three pounds of white sugar. Cover the crock with a cloth and let it stand three weeks to ferment. Skim it, strain and bottle it. In about a month it can be used. — The Gentle Art of Cookery

Other plants beneficial to the circulatory system are acanthus, cucumber, hawthorne, lettuce, nasturtium, olive leaves, and sow thistle.

Drive Safely

Every motorist should remember it is better to be late than to be *the* late. — Springfield Republican

Antibacterial Management of Infection Due to Gram-Negative Bacilli *

Part VI. Some Infections of the Nervous System, Skeletal System, Hematopoietic System, Skin, and Soft Tissues and Comment*

WILLIAM J. MARTIN, M.D.**
Rochester, Minnesota

TUBERCLE BACILLI excluded, the most common bacterial causes of meningitis are meningococci, pneumococci, and type b *Haemophilus influenzae.*[1] Influenzal meningitis is uncommon in persons over 10 and rare in those over 20 years old. Meningitis due to Enterobacteriaceae is common in infants but is uncommon in adults in the absence of penetrating trauma to the central nervous system or underlying diseases such as diabetes and lymphoma. Enterobacteriaceae are responsible in about 75% of cases in neonatal meningitis, and of these *Escherichia coli* is most common. Meningitis from Mimeae organisms is rare. Smears of spinal fluid may indicate a particular regimen, but until cultural reports are available, combined penicillin-G chloramphenicol-sulfonamide therapy has given good coverage. Some workers have used only penicillin and chloramphenicol under such circumstances, and ampicillin alone is currently being investigated in this regard. If *H. influenzae* is causative, chloramphenicol or a combination of streptomycin and a tetracycline is often used, but ampicillin warrants further investigation; the sulfonamides are not commonly used in the definitive treatment of influenzal meningitis today. Management of meningitis due to Enterobacteriaceae depends on the in-vitro susceptibilities; and streptomycin-tetracycline, chloramphenicol, kanamycin, ampicillin, cephalothin, polymyxin B, or colistin may have use. In meningitis from *Pseudomonas,* polymyxin B, or colistin is the drug of choice. In meningitis from Mimeae a tetracycline combined with kanamycin or with polymyxin B, or with colistin is considered.

Cerebritis, brain abscess, and spinal epidural abscess of nontuberculous origin are most often due to staphylococci; however, enterococci and gram-negative bacilli can be causative and, among the latter, *Bacteroides* organisms are not rare. Combined penicillin-G kanamycin-chloramphenicol therapy may be given until microbiologic data are known. Cerebritis may resolve with antibiotic treatment if it is begun early enough. About 10 days are required for encapsulation of a brain abscess and, preferably, surgery is deferred until such is likely. Antibiotic therapy usually is continued for two to three weeks after operation in patients having brain abscess or spinal epidural abscess.

Cavernous sinus thrombosis is rarely due to *H. influenzae* and, in such cases, chloramphenicol has been preferred. Ampicillin warrants investigation.

Although so-called hepatic encephalopathy does not represent an infection of the central nervous system, it is theorized that the condition reflects increased levels of ammonia in the blood since this product of the activity of the intestinal flora on dietary protein may be absorbed systemically from the intestine

**Mayo Clinic and Mayo Foundation: Section of Medicine.

without hepatic detoxification. As aforementioned, neomycin, kanamycin, and paramomycin are the three antibacterial agents most commonly given by the oral route in attempts to decrease the activity of intestinal bacteria in this regard. More recently, alteration of the intestinal flora has been attempted by oral administration of *Lactobacillus* organisms in the form of acidophilus milk. Hypothermia decreases ammonia formation in the intestines of experimental animals and may have potential clinical use in selected cases.

Some Infections of the Skeletal System

Acute Bacterial Arthritis

Acute bacterial arthritis — tuberculosis and specific diseases excluded — is most commonly due to staphylococci, streptococci, and Enterobacteriaceae.[2] Therapy with cephalothin or the conjoint use of a semisynthetic antistaphylococcal penicillin and colistin provide initial coverage. When microbiologic data are known, therapy is modified accordingly. *H. influenzae* may be causative in children, and among the regimens which may have use are streptomycin-tetracycline, chloramphenicol, ampicillin, or cephalothin. If, within 72 hours, the infection has not responded dramatically, surgery is probably required.

Chronic Bacterial Arthritis

In chronic bacterial arthritis, antibacterial therapy is usually ineffective unless bony fragments and fibrous tissue can be removed. When further operation is inappropriate, instillation of proteolytic enzymes may help remove detritus and cleanse the region to allow less hindered action of antibiotics given locally and systemically. Good results are also described with use of local antibiotics in a detergent solution; the penetrating action of the detergent may enable the antibiotics to reach bacteria buried in pus and necrotic tissue. The solution containing the antibiotics and the detergent is irrigated intermittently either by syringe or by an electrically driven suction pump. Hyperbaric oxygenation may have application in the management of certain chronic skeletal infections. Regional perfusion via arterial and venous catheters of such agents as neomycin and colistin is being investigated.

In brucellar osteomyelitis, synovitis, and bursitis, streptomycin-tetracycline is effective when combined with aggressive surgical treatment.[3] In brucellar spondylitis, the antibiotic regimen without surgical intervention may suffice. Acute hematogenous osteomyelitis due to type b *H. influenzae* has been described. Use of ampicillin should be considered.[4]

Intervertebral Disk Infection

Infection of an intervertebral disk after urologic instrumentation appears to result from septic emboli lodging in the spinal column via the vertebral venous plexus. Staphylococci, Enterobacteriaceae, or *Pseudomonas* organisms are commonly responsible. In some patients, abdominal pain may overshadow the distress in the back. Pain may precede roentgenographic evidence of spinal disease by several days or more. A semisynthetic penicillin such as nafcillin plus colistin gives initial coverage if such appears desirable.

Some Infections Associated With Hematopoietic Diseases

Leukemia, lymphoma, multiple myeloma, aplastic anemia, and agranulocytosis predispose to bacteremia due to gram-negative bacilli.[5] In acute leukemia, chronic myelogenous leukemia, aplastic anemia, and agranulocytosis, deficiency of effective neutrophils may be responsible. In chronic lymphatic leukemia, lymphoma, and multiple myeloma, there may be lack of efficient gamma-globulin. In some cases iatrogenic factors such as therapy with adrenocorticosteroids, radiomimetic drugs, and irradiation may be causative. A possible additional factor in some leukemic patients, especially those having chronic lymphatic leukemia, may involve impaired phagocytosis of the leukocytes; however, the impaired phagocytosis may represent a serum (? globulin) defect. Regimens such as nafcillin-streptomycin-tetracycline or penicillin-G kanamycin-chloramphenicol give initial coverage. However, if response is incomplete after 12 hours or so, polymyxin B or colistin is often substituted for streptomycin and kanamycin because of the propensity for pseudomonal bacteremia to develop. Also, since polymicrobic bacteremia is not rare among these patients, penicillin-G or an allied drug is often given initially.

As aforementioned, patients having certain underlying conditions such as sickle-cell disease, Hodgkin's disease, and liver disease may thereby be predisposed to infection from *Salmonella* organisms.

Hypogammaglobulinemia

Hypogammaglobulinemia, unassociated with such diseases as lymphoma, leukemia, and myeloma, may be characterized by increased susceptibility to infection. Among these infections, those of the respiratory tract are often caused by various cocci, but *H. influenzae* has also been implicated, especially in patients having an acquired form of the defect. In the latter patients, administration of gamma-globulin and perhaps conjoint use of a tetracycline or ampicillin may be helpful.

Contaminated Transfusions

Transfusion of contaminated blood is fatal to more than 50% of recipients, and the mechanism of death usually is profound, persistent shock. Contamination of banked blood most commonly is due to endotoxin-producing gram-negative bacilli which grow well at refrigerator temperatures. A centrifuged sample of the blood when smeared and gram-stained will reveal the organisms. Vasopressors and tetracycline-streptomycin or chloramphenicol-kanamycin is given immediately. Renal shutdown is common.

Splenectomy

Because splenectomy has been performed in the management of certain hematopoietic diseases such as thrombocytopenic purpura and congenital hemolytic anemia, the question has arisen whether the patient is thereby predisposed to infection. Studies in this regard were initiated because it was feared that infections, especially those involving the bloodstream, might prove overwhelming in the absence of the clearing function of the spleen. It appears to be the current consensus that the underlying disease for which splenectomy had been performed, rather than the absence of the spleen, is more likely responsible for any increased incidence of infection. In those conditions for which splenectomy may be performed and which do not intrinsically enhance the likelihood of infection, the incidence and extent of future infections may not differ significantly from normal.

Some Infections of the Skin and Soft Tissues

Synergistic bacterial gangrene may be caused by a microaerophilic streptococcus plus either *Staphylococcus aureus* or gram-negative bacillus. Some workers believe that *Streptococcus pyogenes* alone is capable of causing a gangrenous reaction and that the additional organisms which may be cultured represent contaminants.[6] Regimens such as nafcillin-tetracycline or penicillin-G chloramphenicol give coverage until microbiologic data are known.

Peripheral Gangrene

Multiple peripheral gangrene,[7] wherein rapid necrosis of acral parts (most commonly digits) occurs, can be of varied causes. Vascular diseases, hematologic abnormalities, ergotism, cold injury, and numerous other causes may be responsible, but one should also consider overwhelming infection. Diphtheria, as well as meningococcal, pneumococcal, rickettsial, and tuberculous infections have been causative, but endocarditis due to gram-negative bacilli, cholera, and shigellosis must be considered.

Cellulitis

Cellulitis most commonly is streptococcal or staphylococcal in origin but on rare occasions is caused by other organisms including type b *H. influenzae*.[8] Influenzal cellulitis is more likely to occur in children, usually involves the face, and may leave a characteristic bluish-purple discoloration. Bacteremia is

Continued

usually present, and often nose and throat cultures are also positive for *H. influenzae*. Combined streptomycin-tetracycline therapy or use of chloramphenicol or ampicillin is considered.

Tularemia

Cutaneous tularemia reflects contact with the carcasses of wild animals, particularly rabbits, or with a biting arthropod, usually a tick or fly, and the appearance of a skin ulcer within 48 to 72 hours. Tender regional lymph nodes and fever are characteristic. Conjunctival or nasopharyngeal involvement, pneumonia, and bacteremia may occur. Classically, streptomycin is recommended, but one of the tetracyclines is often used in ambulatory patients. When at least 10 days of therapy is given, relapse is rare. A persistent or recurrent bubo may require surgical drainage.

Rat-Bite Fever

Rat-bite fever is of two pathogenic types: that caused by *Streptobacillus moniliformis* and that also known as sodoku which is caused by various spirilla, including *S. minus*. In the United States, the streptobacillary type is more common. The disease may occur after the bite of an infected animal such as a rat, mouse, cat, dog, or weasel. In addition to the local lesion, the two pathogenic types usually share the common manifestations of chills, rash, and intermittent fever. Streptobacillary infection also occurs via the gastrointestinal tract, and is known as Haverhill fever, as when contaminated milk is ingested. Streptobacillary infection may be complicated by endocarditis, arthritis, pulmonary infection, and abscess formation. Complications, including endocarditis, are rare in the spirillary form. In both streptobacillary and spirillary infection, penicillin is preferred, but streptomycin, a tetracycline, or erythromycin may also be effective.

Superficial Ulcers

Superficial ulcers such as those of the lower extremities are of multiple origin — for example, from trauma, varicose veins, and ischemia. Numerous organisms, such as *Staphylococcus* and *Pseudomonas*, may take up residence and it is often difficult to assay their clinical significance. Antibacterial therapy varies with the individual case and the microbiologic findings. Some authorities advise against local antibacterial therapy since it may incite an allergic reaction, thereby aggravating the lesion. Systemic antibacterial therapy in selected patients may help control spreading or ascending infection and contribute to the salvage of a limb or permit amputation at a lower level. Bacteremia is an occasional complication.

Wound Infection

Postoperative wound infections are usually due to *S. aureus*, but Enterobacteriaceae and *Pseudomonas* organisms sometimes require use of pertinent drugs when they appear to represent significant invasion. The more toxic agents like streptomycin, kanamycin, and chloramphenicol are avoided if possible. One is also reluctant to employ a tetracycline because of the conjoint or potential presence of staphylococci. Cephalothin and colistin are often considered if microbiologic data indicate their applicability.

Burn Infections

In victims of severe burns, in addition to debridement and various isolation procedures, numerous regimens have been proposed to lessen the likelihood of infection. Weekly use of a vaccine of heat-killed phenol-preserved *Pseudomonas* plus daily use of hyperimmune plasma from previously vaccinated persons constitute such a regimen. Immersion in silicone fluid and use of silicone-soaked dressings is another. Treatment with dressings kept wet with a 0.5% solution of silver nitrate and changed once or twice daily, combined with intermittent baths in Locke's solution, has its advocates.[9] Exposure, occlusive dressings, and topical application of various antibacterial agents, including sulfonamides, are among the therapeutic techniques advised by other workers. Surface cooling, instituted as soon as possible after the burn and continued for at least 30 minutes, may decrease local reaction to the injury. Systemic antibacterial therapy appears best limited to the first few days and is to be given thereafter only when there are proper clinical and microbiologic indications. It may be that bacteremia due to *Pseudomonas* organisms, staphylococci and so forth, occurs because antibiotic-induced floral changes encourage the invasion of these resistant organisms when unnecessarily prolonged systemic antibacterial therapy is given. Local and systemic use of gentamicin is being investigated against *Pseudomonas* infection.

Comment

In the preceding two decades, advances have been made in the treatment of infections due to gram-negative bacilli, and consequently there is available a more satisfying approach to the individual problem at hand.

In the management of infections due to gram-negative bacilli, in addition to microbiologic considerations, the individual situation may influence selection of the drug to be used; vomiting may disallow use of usual therapy if that therapy ordinarily is given orally. Previous untoward reactions or current intolerance of an agent may disqualify it for use.

Combinations of antibacterial agents should be reserved for situations demanding coverage while microbiologic data are awaited, for polymicrobic infections, and for instances of infections in which there are indications that an enhanced effect is possible. The use of multiple agents in the definitive management of infections due to gram-negative bacilli not only is unnecessary in many cases, but may increase bacterial resistance more than if patients were treated with a single drug. Indiscriminate use of multiple agents may increase bacterial resistance, since such resistance appears to be a direct function of the total amount of a given antibacterial drug used in a given community.

Before antibacterial drugs can become effective, surgical procedures such as drainage of an abscess are occasionally necessary. Adequate surgical attacks in such cases may bring about cure of an infection, but more often eradication of pathogens requires conjoint antibacterical therapy.

Impaired renal function makes mandatory the careful use of certain drugs that are either nephrotoxic or potentially toxic to other organ systems. When resistant organisms are encountered, the intrinsic severity of the infection is the key for deciding whether the risk associated with the use of more toxic antibacterial agents is justified. If renal function is less than normal, the doses of such drugs should be correspondingly reduced.

It should be constantly recalled that antibacterial agents are a mixed blessing because, in addition to resulting in untoward reactions, they may cause emergence of resistant organisms, their use may result in a diagnostic loss if they are employed before diagnosis is established, and they are expensive.

Adequate management of infection due to gram-negative bacilli requires close cooperation between the clinician and the microbiologist. Careful clinical and microbiologic analysis of the individual infection and the use of discrimination in attempts at therapy are mandatory; there is little place for diagnostic or therapeutic dogma in the management of serious infections due to gram-negative bacilli. It may be necessary at any stage in the management of gram-negative bacillary infections to re-evaluate, re-examine, and alter the regimen.

Not all infections due to gram-negative bacilli can be eradicated any more than can all disease in any sphere of medical endeavor. Failure in the management of a given patient should prompt consideration of the nature of a possible underlying lesion, since certain diseases like leukemia, multiple myeloma, and metastatic malignancy, which are likely to be complicated by infection due to gram-negative bacilli, may make recovery impossible. The prognosis may also be influenced by the duration of infection before institution of appropriate management, and the occurrence of complications such as endotoxin shock and superinfection. In regard to superinfection, periodic microbiologic study of the sputum and stools during ther-

Continued

apy may reveal floral changes in time to avert clinical manifestations of superinfection.

Medical Men and Music*

"I could not stamp out the intense love of music which at my birth was implanted in me. I whistled as a child early, and at all times. My earliest impressions were of the notes I produced; they came as freely as they came from the bobolink who, dancing on the dry mullein stalk, warbles forth his rich notes in our spring days."**

Thus did the eminent clinician, Henry Ingersoll Bowditch (1808-1892), reminisce on his boyhood. Though he never learned to play an instrument, having once tried the bassoon and failed to elicit more than a few whoops thereon, appreciation of music was his lifelong joy and inspiration.

Among earlier medical men who loved music was physician Felix Platter (1536-1614) of Basel, who collected instruments and performed proficiently on several of them, among which was the lute, wherewith he serenaded his sweetheart.

Seventeenth century medical men noted for their love of music included Hermann Boerhaave (1668-1738) of Leyden and John Arbuthnot (1667-1735), Alexander Pope's medical advisor, who composed sacred anthems, one of them the still extant "As Pants the Heart." Of Boerhaave one of his biographers says:

"When business was over, he took the exercise of riding or walking, and when weary, revived himself with music, his most delightful entertainment, being not only a good performer on several instruments, particularly the lute, which he accompanied also with his voice, but a good theorist likewise in the science, having read the ancient and best authors on the subject, as appears by the lectures he gave on sound and hearing."**

In order to form an immaculate member of a flock of sheep one must, above all, be a sheep. — Albert Einstein

when congestion is complicated by sulfa-susceptible bacterial invaders in the upper respiratory tract...

re-enforce your decongestant therapy

prescribe economical Trisulfaminic®

Each tablet contains: Triaminic® 25 mg. (phenylpropanolamine hydrochloride 12.5 mg., pheniramine maleate 6.25 mg., pyrilamine maleate 6.25 mg.); Trisulfapyrimidines, U.S.P. 0.5 Gm. (sulfadiazine 0.167 Gm., sulfamerazine 0.167 Gm., sulfamethazine 0.167 Gm.)

PHARMACOLOGY: Triaminic decongests and promotes drainage of nasal and paranasal passages, and prevents any further histamine-induced damage; the triple sulfonamides inhibit susceptible bacterial invaders. INDICATIONS: For congestion and infection of the upper respiratory tract caused by sulfa-susceptible organisms. DOSAGE: Adults: 2 to 4 tablets initially, followed by 2 tablets every 6 hours. Medication should be continued until patient has been afebrile for 3 days. ADVANTAGES: The advantages of Trisulfaminic in upper respiratory infections are: freedom from narcotics or alcohol; therapeutic reliability; safety; economy; ease of administration; freedom from potential sensitization to broad-spectrum antibiotics which may be reserved for lower respiratory or other infections caused by susceptible organisms. CONTRAINDICATIONS: Contraindicated in sulfonamide and antihistamine sensitivity, impaired renal function, pregnancy approaching term, and in premature infants and newborn infants during the first month of life. Do not use in patients with glaucoma, prostatic hypertrophy, stenosing peptic ulcer, pyloroduodenal or bladder neck obstruction. WARNING: Use only after careful evaluation in patients with liver or renal damage, urinary obstruction, or blood dyscrasias. Deaths have been reported from hypersensitivity reactions with administration of sulfonamides. In intermittent or prolonged therapy, blood counts and liver and kidney function tests should be performed periodically. Sulfonamide therapy may potentiate the hypoglycemic action of sulfonylureas. PRECAUTIONS: Use with caution in patients with histories of significant allergy or asthma. Assure an adequate fluid intake. Because the antihistamines may cause drowsiness of varying degree, warn patients about activities requiring alertness such as driving a car or operating dangerous machinery. Use with caution in the presence of hypertension, hyperthyroidism, cardiovascular disease and diabetes. ADVERSE REACTIONS: As in all sulfonamide therapy, the following reactions may occur: headache, nausea, vomiting, diarrhea, icterus, hepatitis, pancreatitis, urticaria, rash, fever, cyanosis, hematuria, crystalluria, proteinuria, blood dyscrasias, petechiae, purpura, neuropathy and injection of the conjunctiva and sclera. If one or more of these reactions occur, the drug should be discontinued. With antihistaminic therapy there have been reports of sedation varying from mild drowsiness to deep sleep, dizziness, lassitude, inability to concentrate, fatigue, incoordination, tinnitus, blurred vision, diplopia, euphoria, nervousness, insomnia, tremors, palpitation, hypotension, headache, chest tightness, urinary frequency, dysuria, tingling of the hands, dryness of the mouth, throat, and nose, gastrointestinal disturbances such as epigastric distress, anorexia, nausea, vomiting, constipation and diarrhea and very rarely, leukopenia and agranulocytosis. Adverse reactions reported with the use of sympathomimetic amines include anxiety, tension, restlessness, nervousness, tremor, weakness, insomnia, headache, palpitation, tachycardia, angina, elevation of blood pressure, sweating, mydriasis, anorexia, nausea, vomiting, dizziness, constipation, and dysuria due to vesicle sphincter spasm. PACKAGE INFORMATION: Trisulfaminic Tablets: Supplied in bottles of 100 tablets. CAUTION: Federal law prohibits dispensing without prescription.

DORSEY LABORATORIES • *a division of The Wander Company* • **LINCOLN, NEBRASKA**

Diagnosis:

cystitis?
pyelonephritis?
pyelitis?
urethritis?
prostatitis?

in any case,
usually gram-negative*

Therapy:

two 500 mg. Caplets® q.i.
(initial adult dose)

NegGram

Brand of
nalidixic aci

a specific anti-gram-negative

eradicates most urinary tract infections...

- Low incidence of untoward effects; no fungal overgrowth, crystalluria, ototoxic or nephrotoxic effects have been observed.
- "Excellent" or "good" response reported *in more than 2 out of 3* patients with either chronic or acute gram-negative infections.[1]

*As many as 9 out of 10 urinary tract infections are now caused by gram-negative organisms: E. coli, Klebsiella, Aerobacter, Proteus, Paracolon or Pseudomonas[2]... However, infections of the urethra and prostate caused by non-gonococcal gram-negative organisms are believed to be less prevalent.

Indications: Urinary tract infections caused by gram-negative and some gram-positive organisms.

Side effects: Mainly mild, transient gastrointestinal disturbances; in occasional instances, drowsiness, fatigue, pruritus, rash, urticaria, mild eosinophilia, reversible subjective visual disturbances (overbrightness of lights, change in visual color perception, difficulty in focusing, decrease in visual acuity and double vision), and reversible photosensitivity reactions. Marked overdosage, coupled with certain predisposing factors, has produced brief convulsions in a few patients.

Precautions: As with all new drugs, blood and liver function tests are advisable during prolonged treatment. **Pending further experience, like most chemotherapeutic agents, this drug should not be given in the first trimester of pregnancy. It must be used cautiously in patients with liver disease or severe impairment of kidney function.** Because photosensitivity reactions have occurred in a small number of cases, patients should be cautioned to avoid unnecessary exposure to direct sunlight while receiving NegGram, and if a reaction occurs, therapy should be discontinued. The dosage recommended for adults and children should not arbitrarily be doubled unless under the careful supervision of a physician. Bacterial resistance may develop.

When testing the urine for glucose in patients receiving NegGram, Clinistix® Reagent Strips or Tes-Tape® should be used since other reagents give a false-positive reaction.

Dosage: Adults: Four Gm. daily by mouth (2 Caplets® of 500 mg. four times daily) for one to two weeks. Thereafter, if prolonged treatment is indicated, the dosage may be reduced to two Gm. daily. Children may be given approximately *25 mg. per pound* of body weight per day, administered in divided doses. The dosage recommended above for adults and children should not arbitrarily be doubled unless under the careful supervision of a physician. Until further experience is gained, infants under 1 month should not be treated with the drug.

How supplied: Buff-colored, scored Caplets® of **500 mg. for adults,** conveniently available in bottles of 56 (sufficient for one full week of therapy) and in bottles of 1000. **250 mg. for children,** available in bottles of 56 and 1000.

Grand Rounds

*Intestinal Amebiasis**

WILLIAM TORP, M.D.
Medical Resident

OF THE SEVERAL species of amebae which inhabit the G.I. tract of man, only one, Endamoeba histolytica, is pathogenic. In spite of this the diagnosis may be quite difficult to establish, and the investigator may find this ameba to be extremely elusive.

Amebiasis, intestinal and extra-intestinal, has virtually a world-wide distribution but is most prevalent in subtropical and tropical environs, especially in areas where the populace lives under primitive conditions.

Incidence

Incidence of the disease in the United States has been the subject of some discussion (Table 1). McGoth, in 1960, published results of a study done at the Mayo Clinic in which he arrived at an average figure of 2.1 percent over a 20-year period, with annual incidence varying from 1.1 to 3.8 percent.[2] This was based on findings of stool examinations in patients with gastrointestinal symptoms, approximately 3 percent of the Mayo Clinic patient load from 1937 to 1957. Sepulveda from the University of

TABLE I
Incidence of Intestinal Amebiasis in the United States

1913	Giffin — Mayo Clinic	1,700 patients	4.6%
1916	Sanford — Tulane	5,000 patients	10.7%
1923	Boech and Stiler Federal and State Hospitals	8,000 patients	4.1%
1926	Craig — United States		10.0%

*Presented as a Medical Grand Rounds at Hennepin County General Hospital, June 7, 1966.

Continued

Mexico states that 15 to 30 percent of the adult population in Mexico has intestinal amebiasis.[3] Many of these people are asymptomatic. Faust, in a study done in Columbia, reports an incidence of 33.5 percent positive stool specimens in 651 low-income city dwellers over a five-month period. None of these had a frank case of amebic dysentery.[4] In contrast to this he found the incidence of positive stool specimens to be 6.4 percent among 93 patients in a private clinic. Elsden-Dew reported an incidence of approximately 26 percent in a study from Durban, South Africa.[5] Armas-Cruz reports an incidence of almost 40 percent based on a two-year study of 3,500 clinic patients in Chile.[6]

It is apparent from these figures that the incidence of amebiasis in the United States is probably much lower than the stated 10 percent and that the incidence in endemic areas is quite high.

The Organism

While man has been troubled with dysentery for centuries it has been only in the past 90 years that E. histolytica has been identified as one of the causes. In 1870 amebae were found in the stool of cholera patients, but no etiological relationship was established.[4] A few years later Losch, in Russia, found amebae containing red blood cells in the stool of a patient with "relapsing dysentery". He then produced dysentery in dogs by giving dysenteric stool by mouth and rectum. He also observed the organism in autopsy specimens but did not make the observation that these amebae, which he called "Amoeba coli", were the causative agents of the disease. At the turn of the century Endamoeba histolytica and Endamoeba coli were differentiated, and in 1913 Walker and Sellards, working in the Philippine Islands, showed that E. histolytica would produce dysentery in some volunteer patients while E. coli would not.[7]

In 1919, Dobell described and illustrated five species of ameba found in man,[7] only one of which, Endamoeba histolytica, is pathogenic. Some of the characteristics of these organisms are shown in Table 2. If the trophozoite forms are preserved well enough to be active, the diagnosis can be made on this basis. However, identification of cysts is usually easier.

The life cycle of E. histolytica is interesting and should be understood. Man, several species of monkeys, dogs and rats may serve as natural reservoirs for this organism, and the kitten, guinea pig, hamster and rabbit are all good laboratory hosts.[1,5]

Mode of Infection

In order to become infected one must ingest the cystic form which, with proper environmental conditions, can be very hardy. The cyst passes to the proximal portion of the small bowel where the cyst wall is discarded and the metacyst emerges. A short time later the cytoplasm divides and each of the nuclei forms very small metacystic trophozoites. These reach the cecum and may invade the mucosal layer causing tissue infection. They continue to multiply by binary fission. The trophozoites may continue moving through the large bowel, and as the stool becomes dehydrated the organism eliminates all undigested inclusion bodies and takes on a round form, the precystic stage. It then forms a thin covering around itself and becomes a cyst. The single nucleus that is present divides until there are four nuclei, and the cyst is then said to be mature. This maturity may take place in the rectum or after the stool has been passed. It is interesting to note that trophozoites in diarrhea stools do not encyst.

The trophozoites usually invade the intestinal mucosa between rugae, in the lumen of a vertical gland or between glands. They then migrate toward the muscularis mucosae, at the same time establishing a pyramidal-shaped colony. The opening on the surface is usually quite small and discrete and may be hemorrhagic or have a large amount of exudate. They are easily visible to the naked eye. Cross section of the ulcer shows much more activity than appears evident from the surface.

Bacterial Flora

There seem to be other factors necessary for infection in addition to ingestion of material containing amebic cysts. It is apparently important to have certain bacterial flora present. Raffensperger relates an experiment done by Westphal in 1937 in which he swallowed washed cysts of E. histolytica. He showed cysts and trophozoites in his stool in two days but did not develop any symptoms until after he ingested 50 cc. of ameba-free stool suspension from a patient with amebic dysentery.[7] Phillips and his associates go so far as to say that more widespread use of broad-spectrum antibiotics may be partially responsible for some decline in incidence of the symptomatic disease.[9] In a study of stool specimens from 1773 hospital patients and staff, they demonstrated E. histolytica in 23. Of these 23 persons, 22 had no previous exposure to broad-spectrum antibiotics. This was compared to 100 with negative stools, 12 of whom had previous broad-spectrum antibiotics.

TABLE 2

Ameba Found in Human G.I. Tract

Name	Stages	Trophozoite	Cyst
E. histolytica	5 (Trophozoite, pre-cystic, cystic, meta cystic, meta cystic trophozoite)	Large race 18-30 micra Small race 9-15 micra May contain bacteria, leukocytes or RBC. Rapid protruding and retracting of pseudopodia.	11-18 micra 6-11 micra 1-4 nuclei depending on maturity
Endamoeba coli	3 (Trophozoite, pre-cystic, cystic)	20-30 micra Pseudopodia small, blunt and not as prominent as E. histolytica. Slow movement, may contain bacteria but usually no RBC.	12-35 micra 1-32 nuclei
Endolimax nana	3 (Trophozoite, pre-cystic, cystic)	6-15 micra	7-8 micra oval shape 1-4 nuclei
Iodamoeba butschlii	2 (Trophozoite and cystic)	10-15 micra	Single nucleus irregular shape
Dientamoeba fragilis	1 (Trophozoite only)	8-9 micra Active	

Continued

Dietary Influence

Elsden-Dew in his study of amebiasis in South Africa found that among the Indians and Europeans the disease was asymptomatic or mild, while in the African it was acute and fulminant.[5] He feels that this may be due to dietary differences in that the Africans he studied had diets with much maize and little milk. He also refers to a study done on two communities in Tennessee, both of which used large amounts of corn in the diet, but one of which had milk and vegetable supplements. The latter group had a much lower incidence of acute amebiasis than the other group. Elsden-Dew feels that the areas of the world with high incidence of amebiasis are also areas in which corn is a major part of the diet.

Trauma to Intestines

It has also been shown that traumatizing the bowel may make a laboratory animal more susceptible to infection. Faust makes the point that travelers may make themselves more amebiasis-prone by eating new types of fruits or condiments or by taking abnormal amounts of alcoholic beverages, causing irritative trauma to the bowel.[1]

Infested Food

The disease is spread directly by several vehicles. Prior to the Chicago epidemic in 1933, water was not considered a source of contamination and most attention was focused on infected food handlers.[10] This epidemic resulted in at least 52 deaths and complete revision of the plumbing in the hotel which was the source of infection.

Other modes of transmission include vegetables fertilized with human excreta, flies, cockroaches, fomites and clothing.

Diagnosis

Diagnosis can be extremely difficult. Not only can the organisms be very difficult to isolate and identify, but the clinical picture of the disease may be extremely variable.

Armas-Cruz reports that less than 10 percent of the patients in his study with positive stool specimens for E. histolytica showed clinical signs of the disease.[6] Faust did not have a frank case of dysentery in a group of over 200 with positive stools.[4] Many of the cases in Table 1 were picked up on routine studies of stool specimens in asymptomatic persons.

Most of the published series referred to in this paper had very rigid criteria for diagnosis. All emphasized the need for expert staff in interpreting findings in stool specimens, biopsy material, rectal smears, etc.

For diagnosis Juniper[11] required active colonic ulceration with acute symptoms which responded to anti-amebic therapy and typical trophozoites on a permanent stain prep. Fifty-two of his patients had diarrhea with eight to 20 stools per day; 33 had gross, bloody stools, and 22 had stools with blood-streaked mucous. The three patients without diarrhea had several formed stools per day. Many had other gastrointestinal symptoms which included mild nausea and vomiting, abdominal cramps, and weight loss averaging 20 pounds.

Proctoscopy and Biopsy

Proctoscopic examination was done on 46 patients, 40 of whom showed scattered ulcerations in otherwise normal appearing mucosa. Rectal biopsy was done on 22 of the 46 proctoscopic examinations; on 18 of these trophozoites were demonstrated.

In an earlier report on use of rectal biopsies, Juniper cited 14 cases, all of which were positive.[12] He emphasizes the necessity for care in handling and fixing the specimen. It is extremely important to study the exudate overlying the ulcer, as this is where trophozoites are most commonly found. The patient should not have an enema before the proctoscopy and the biopsy, as the exudate will be washed out. Serial sections were done on the biopsy material in spite of the fact that all but one of the patients had trophozoites on a single slide. Half of the patients showed trophozoites in all 15 of the serial sections of the biopsy.

The recommended method of obtaining exudate from a rectal ulcer is to scrape the surface or to use suction and a small pipette.

Ellenberg published a report on sigmoidoscopic findings in 176 symptomatic and asymptomatic cases and found typical lesions in 125 of the 176 patients.[13]

Stool Examination

In examining stool specimens care must be taken to get a proper sample. If stool is formed one will find cysts only; if the stool is dysenteric E. histolytica will be in the trophozoite stage. Faust states that unformed stool must be examined within one hour and preferably within thirty minutes so that trophozoites will still be mobile. Formed stools on the other hand may be held for 24 hours at 70 degrees F. or for seven to 10 days in refrigerator without affecting the characteristics of the cyst. Faust states that the yield of a positive result on a single specimen is not more than 20 to 27 percent; but using a concentrating technique with zinc sulfate can double this yield. Because trophozoites and cysts are not excreted in a uniform manner, Faust recommended examination of three to four stool specimens which are passed every second or third day for better and more reliable results.

Saline purge may be helpful if the lesions are primarily in the cecum, as the trophozoite may disintegrate rather than encyst during passage through the large bowel.

Laboratory Procedures

Culture methods are available, but the technique is apparently quite difficult even in expert hands. Juniper was unable to culture the organism in any of a series of 27 documented cases of amebic colitis.[11]

Complement fixation titers are also available but the method is apparently still somewhat experimental.

Barium enema may be helpful. Juniper had positive results in eight of 28 patients (ulceration, ameboma, conical spasticity of the colon).

Non-specific findings that may be helpful include mild fever, mild elevation of the white count, mild anemia. There may be a slight increase in eosinophils.

Treatment

The methods of treatment of intestinal amebiasis are many and varied and depend on whether a patient is an asymptomatic carrier or is having an acute episode.

Continued

There are three categories of drugs used in treatment: (1) tissue amebicides, (2) those amebicides which act mainly in the gut, and (3) broad-spectrum antibiotics. Common tissue amebicides are emetine and chloroquine, while diiodo-hydroxyquinoline (diodoquine) and the arsenical derivatives (e.g., carbarsone) act mainly in the gut. Wilmot presents a very concise view of these agents in Current Therapy.[14] Emetine has some definite drawbacks in that it is toxic to myocardium and other muscle; but it is none the less used by many investigators.

Tissue Amebicides

Wilmot suggests using one of the amebicides which acts in the gut for treatment of an asymptomatic patient. He makes the point that most cases of amebiasis will have parasites in the tissue as well as in the gut and therefore must be treated with that in mind. For amebic dysentery he recommends either a regimen in which tetracycline, diodoquine and chloroquine are given simultaneously; otherwise, emetine, tetracycline and diodoquine are used. Juniper suggests a similar program but feels antibiotics are not routinely indicated.[11] In his study of 55 patients in which 54 were treated, there were six deaths, with the rest responding to therapy.

Elsden-Dew, in Africa, uses emetine during the hospital stay, and the patient is discharged on carbarsone.

Amebicides Acting in the Gut

Most[15] recommends use of an amebicide that acts in the gut for the asymptomatic carrier and mild case. He feels diodoquine is best and gives a 75 percent cure. Carbarsone may be used if necessary. For the acute case he gives emetine and tetracycline followed by diodoquine and then by chloroquine to remove any ameba in the liver not eliminated by emetine.

Antibiotics

There has been some discussion as to whether antibiotics (namely tetracycline) have a place in this therapy.[11] Juniper feels that they should be reserved for control of symptoms in children when they are unable to take the oral arsenicals. Most also reserves antibiotics for the more severe cases, while Wilmot uses them more liberally.

The feeling has been that tetracycline, probably the most commonly used antibiotic, acts on the intestinal flora only; but McHardy and Frye in 1954 did some in-vitro studies which showed that fumagillin, carbomycin and tetracycline had some direct action on the ameba.[16] Fumagillin acts directly on the organism and has no antibacterial effect. McHardy showed excellent results with fumagillin in a study of 175 patients.[17] The drug is not widely used today; this may be partially due to its side effects of gastrointestinal symptoms and skin eruptions.

Complications

Complications of the disease include extra-intestinal infection, bleeding, perforation and stenosis.

Kean analyzed 149 of the 240 fatal cases of amebiasis from the Armed Forces Institute of Pathology.[18] It is interesting to note that a correct clinical diagnosis was made in only one third of the cases prior to death, and of those with liver abscesses only half were recognized. The causes of death are summarized in Table 3.

Most common extra-intestinal sites of infection are (in descending order) the liver (acute amebic hepatitis and abscess), the lungs and pleura, the intracranial areas, and the skin, although these are extremely rare.

Summary

In summary, we have a disease which is caused by a protozoan, the identification of which is often difficult. The severity of the disease may vary from that of an asymptomatic carrier to that of acute, fulminating, possibly fatal proportions. It may be successfully treated with a combination of amebicidal drugs, one of which acts in the gut and the other in the tissues. Tetracycline may be used against ameba in the gut. Extra-intestinal infections may occur and require more rigid therapy than that outlined above. This disease continues to be a major public health problem in undeveloped areas of the world as well as in any area where proper sewage disposal is not carried out.

Case Report

The patient, a 22-year-old negro female, stated that she was feeling well until approximately one year prior to admission when she developed diarrhea during an illness which she called "flu". She was having up to ten stools a day which she described as watery and varying in quantity. The stool pattern persisted through her time of admission. Four months after her onset of diarrhea the patient noted bloody stools which varied in color from light red at onset to dark red at time of admission. During this time she has had a 32-pound weight loss and intermittent episodes of nausea and vomiting.

She has been living in Minneapolis but has visited Chicago and Denver. She is not aware of any exposure to infectious disease. She admits to smoking one package of cigarettes and drinking one bottle of beer each day. Her eating habits have been irregular.

Physical examination showed a thin, negro female. Proctoscopic examination revealed grossly normal mucosa with the exception of many small, punctate craters,

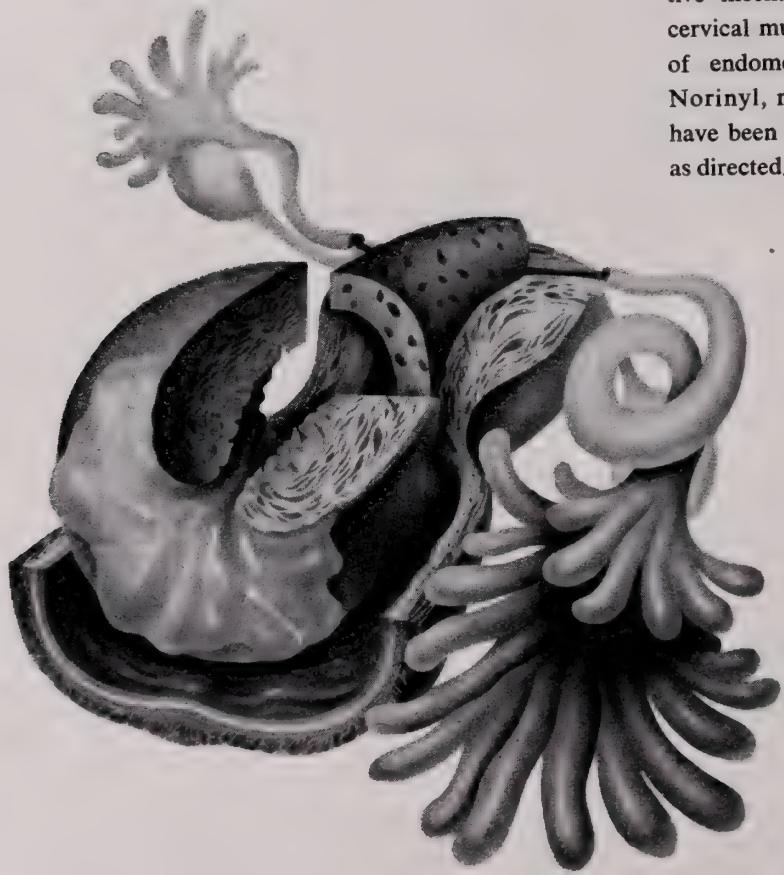
Norinyl® tablets
(norethindrone 2 mg. $\bar{c}$ mestranol 0.1 mg.)

for multiple contraceptive action that has produced a record of unexcelled effectiveness

inhibition of ovulation by means of 2 time-proved hormonal agents

production of a cervical mucus hostile to sperm motility and vitality

creation of an endometrium unreceptive to egg implantation



no unplanned pregnancies
Norinyl provides multiple action for maximum assurance of success. It does not depend on ovulation inhibition alone for contraceptive effectiveness. The mechanism of action of combined hormonal therapy results in ovulation inhibition reinforced by other protective mechanisms, including a hostile cervical mucus[1-13] and an acceleration of endometrial changes.[1-3,7-16] With Norinyl, no unplanned pregnancies have been reported to date when used as directed.

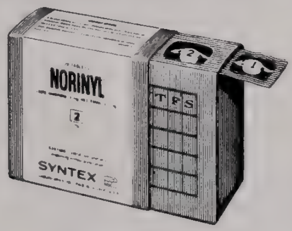
plus important supportive benefits that help her through those critical early months of oral contraception

low incidence of side effects

Low incidence of BTB and spotting, nausea and amenorrhea tends to minimize side effect problems and increases patient cooperation.

no confusion about dosage

An unbreakable "confusionproof" package makes it easy to adhere to prescribed dosage schedule: individually sealed tablets numbered from 1 through 20 *plus* monthly calendar record enables patient to double-check dosage intake by day and corresponding tablet number.



Contraindications: Thrombophlebitis or pulmonary embolism (current or past). Existing evidence does not support a causal relationship between use of Norinyl and development of thromboembolism. While a study which was conducted does not resolve definitively the possible etiologic relationship between progestational agents and intravascular clotting, it tends to confirm the findings of the Ad Hoc Advisory Committee appointed by the Food and Drug Administration to review this possibility. Cardiac, renal or hepatic dysfunction. Carcinoma of the breast or genital tract. Patients with a history of psychic depression should be carefully studied and the drug discontinued if depression recurs to marked degree. Patients with a history of cerebral vascular accident.

Warning: Discontinue medication pending examination if there is sudden partial or complete loss of vision, or if there is a sudden onset of proptosis, diplopia or migraine. If examination reveals papilledema or retinal vascular lesions, medication should be withdrawn.

Precautions: By May 1963, experience with norethindrone 2 mg.—mestranol 0.1 mg. had extended over 24 months. Through miscalculation, omission or error in taking the recommended dosage of Norinyl, pregnancy may result. If regular menses fail to appear and treatment schedule has not been adhered to, or if patient misses two menstrual periods, possibility of pregnancy should be resolved before resuming Norinyl. If pregnancy is established, Norinyl should be discontinued during period of gestation since virilization of the female fetus has been reported with oral use of progestational agents or estrogen. When lactation is desired, withhold Norinyl until nursing needs are established. Existing uterine fibroids may increase in size. In metabolic or endocrine disorders, careful clinical preevaluation is indicated. A few patients without evidence of hyperthyroidism had elevated serum protein-bound iodine levels, which in the light of present knowledge, does not necessarily imply hyperthyroidism. Protein-bound iodine increased following estrogen administration. Bromsulphalein retention has occurred in up to 25% of patients without evidence of hepatic dysfunction. Studies from 24-hour urine collections have shown an increase in aldosterone and 17-ketosteroids and decrease in 17-hydroxycorticoid levels. Thus, Norinyl should be discontinued prior to and during thyroid, liver or adrenal function tests. Because progestational agents may cause fluid retention, conditions such as epilepsy, migraine and asthma require careful observation. Thus far no deleterious effect on pituitary, ovarian or adrenal function has been noted; however, long-range possible effect on these and other organs must await more prolonged observation. Norinyl should be used with caution in patients with bone, renal or any disease involving calcium or phosphorus metabolism.

Side Effects: Intermenstrual bleeding; amenorrhea; symptoms resembling early pregnancy, such as nausea, breast engorgement or enlargement, chloasma and minor degree of fluid retention (if these should occur and patient has not strictly adhered to medication plan, she should be tested for pregnancy); weight gain; subjective complaints such as headache, dizziness, nervousness, irritability; in a few patients libido was increased. In a total of 3,090 patients, 2.2% discontinued medication because of nausea.

NOTE: See sections on contraindications and precautions for possible side effects on other organ systems.

Dosage and Administration: One Norinyl tablet orally for 20 days, commencing on day 5 through and including day 24 of the menstrual cycle. (Day 1 is the first day of menstrual bleeding.)

Availability: Dispensers of 20 and 60 tablets; bottles of 100.

Oliver Wendell Holmes on Elbow Grease

You are now fresh from the lecture-room and the laboratory. You can pass an examination in anatomy, physiology, chemistry, materia medica, which the men in large practice all around you would find a more potent sudorific than any in the Pharmacopoeia. These masters of the art of healing were once as ready with their answers as you are now, but they have got rid of a great deal of the less immediately practical part of their acquisitions, and you must undergo the same depleting process. Hard work will train it off, as sharp exercise trains off the fat of a prize-fighter.

Medical Men on Postage Stamps*

Andreas Vesalius (1514-1564), Dutch physician who modernized anatomy by his 'odious' dissection of human bodies and so revolutionized the practice of surgery, was honored for his achievements by the issuance of a commemorative Belgian postage stamp in 1964.

Book Reviews

That is a good book which is opened with expectation and closed with profit. —
Alcott

HERITABLE DISORDERS OF CONNECTIVE TISSUE — Book Review, McKusick, Victor A., Third Edition, C. V. Mosby Company, St. Louis (1966).

This is an exceptional book which is worthy of study by any practitioner of medicine, be he a generalist or specialist, a researcher or clinician. The author attempts and succeeds in correlating widely scattered clinical observations on the inherited disorders of connective tissue, i.e., the Marfan syndrome, osteogenesis imperfecta, alkaptonuria, pseudoxanthoma elasticum, the mucopolysaccharides — and other rarer syndromes. The multitude of observations from all areas of clinical medicine and research, as well as genetics and pathology, make the book of widespread interest for all practitioners of medicine. In particular, specialists in internal medicine, pediatrics and general practice will find the book to be valuable. The correlation of the complications and variations in these diseases and the many excellent photographs and illustrative case histories make reading or scanning this book a pleasure.

Those readers who read the first two chapters on the clinical behavior of hereditary syndromes and the biology of the normal connective tissue as well as the detailed discussions of the diseases will become convinced of Dr. McKusick's conviction "that clinical investigation of pathological states is as legitimate a method as any other for studying biology". Hopefully, they will be encouraged to make further observations and ultimately, contributions to the literature on these or other diseases.

The final virtue of this excellent book is the comprehensive bibliography which accompanies each of the diseases discussed. These bibliographies make it possible for anyone interested in further study to have easy access to the important literature on each of these diseases.

TWINS: TWICE THE TROUBLE, TWICE THE FUN — Betsy Holland Gehman, J. B. Lippincott Co., Philadelphia and New York, 1965, 223 pages.

This field manual for mothers of twins cascades from the pen of Betsy Gehman — a former woman's magazine editor. She wrote it, she says, because there were few books to consult when she struggled with the problems of her own twins. Out of her experiences Mrs. Gehman welds a personal and practical guidebook for distraught or curious mothers. She devotes about one third of the space to the medical aspects of twins. The high-spirited, spockian narrative rests on well ordered facts sifted from experts. Statistical probabilities, physiology of fraternal and identical twins, techniques of breast feeding, articles in medical periodicals — all come under maternal scrutiny. Physicians who treat or advise mothers of twins will enjoy the book.

FERMENT IN MEDICINE: A STUDY OF THE ESSENCE OF MEDICAL PRACTICE AND ITS NEW DILEMMAS — Richard M. MaGraw, W. B. Saunders Co., Philadelphia and London, 1965. 273 pages, $8.50.

Richard MaGraw, a psychiatrist and internist, who heads the Comprehensive Care Clinic at the University of Minnesota, generates both heat and light in this blunt dissection of modern medicine. MaGraw sallies forth with a series of vignettes on such sensitive issues as financial third parties, fragmented care by specialists, doctor-administrator conflicts, the town-gown muddle, the dimming of professional prestige, the impact of automation, and the encroachment of government.

The picture that MaGraw paints is not flattering. Medicine emerges as a ponderous, shambling creature who has had blinders on in the past and is nearsighted for the future. Through all discussions runs the recurrent theme that times have changed and that doctors will have to resolve their grief complex about loss of status if they are to effectively contribute to society and medicine.

The ideas for this book were born and nurtured during 15 years of giving seminars for medical students. At times, MaGraw's academic idealism outruns his tact. Many practitioners will find the book's professorial flavor distasteful and unrealistic. Those active in medical politics will probably be offended. But most doctors, I believe, will admire MaGraw for his courage in speaking his mind. He is a provocative critic whose facts are well ordered and well documented. The book ends with a frankly emotional appeal for a new set of attitudes by the next leaders of medicine.

now...introducing a new high-strength dosage forn

SIGNEM

A 'MAXIMUM SECURITY' ANTIBIOTIC*

* THE BROAD RANGE DEPENDABILITY OF TETRACYCLINE
long established as the broad-spectrum agent of first choice in a wide variety of infections

* WITH THE ADDED SECURITY OF MEDIUM-SPECTRUM REINFORCEMENT
triacetyloleandomycin is highly active against the common 'coccal' pathogens, including certain strains of staphylococci resistant to penicillin and tetracycline

* ESPECIALLY VALUABLE IN U.R.I.
provides decisive therapy in acute respiratory infections and other conditions in which staphylococci, streptococci or mixed flora are frequently encountered

* NOW AVAILABLE IN NEW STRENGTH FOR NEW CONVENIENCE AND ECONOMY
Signemycin 375—high-potency capsules for simpler administration, greater patient economy

YCIN® 375

(tetracycline 250 mg.
triacetyloleandomycin 125 mg.)

Indications: Indicated in the therapy of acute severe infections caused by susceptible organisms and primarily by bacteria more sensitive to the combination than to either component alone. In any infection in which the patient can be expected to respond to a single antibiotic, the combination is not recommended. Signemycin should not be used where a bacteriologically more effective or less toxic agent is available. *Triacetyloleandomycin, a constituent of Signemycin, has been associated with deleterious changes in liver function.* See precautions and adverse reactions.

Contraindications: Contraindicated in individuals who have shown hypersensitivity to any of its components. Not recommended for prophylaxis or in the management of infectious processes which may require more than 10 days of continuous therapy. If clinical judgement dictates therapy for longer periods, serial monitoring of liver function is recommended. Not recommended for subjects who have shown abnormal liver function tests, or hepatotoxic reactions to triacetyloleandomycin.

Precautions and Adverse Reactions: Triacetyloleandomycin, administered to adults in daily oral doses of 1.0 gm. for 10 or more days, may produce hepatic dysfunction and jaundice. Adults requiring 3 gm. of Signemycin initially should have liver function followed carefully and the dosage should be reduced as promptly as possible to the usual recommended range of 1.0 to 2.0 gm. per day. Present clinical experience indicates that the observed changes in liver function are reversible after discontinuation of the drug. Use with caution in lower than usual doses in cases with renal impairment to avoid accumulation of tetracycline and possible liver toxicity. If therapy is prolonged under such circumstances, tetracycline serum levels may be advisable. In long term therapy or with intensive treatment or in known or suspected renal dysfunction, periodic laboratory evaluation of the hematopoietic, renal and hepatic systems should be done. Formation of an apparently harmless calcium complex with tetracycline in any bone forming tissue may occur. Use of tetracycline during tooth development (3rd trimester of pregnancy, infancy and early childhood) may cause discoloration of the teeth. Reversible increased intracranial pressure due to an unknown mechanism has been observed occasionally in infants receiving tetracycline. Glossitis, stomatitis, proctitis, nausea, diarrhea, vaginitis and definite allergic reactions occur rarely. Severe anaphylactoid reactions have been reported as due to triacetyloleandomycin. Photosensitivity and photoallergic reactions (due to the tetracycline) occur rarely. Medication should be discontinued when evidence of significant adverse side effects or reaction is present. Patients should be carefully observed for evidence of overgrowth of nonsusceptible organisms including fungi, which occurs occasionally, and which indicates this drug should be discontinued and appropriate therapy instituted. Steps should be taken to avoid masking syphilis when treating gonorrhea.

Abstracts, Briefs and Commentaries

FEEDING METHODS

The relation between the feeding method used during infancy and later personality structure has been debated by generations of physicians. Although breast feeding is believed to have psychological advantages over bottle or cup feeding, it is difficult to find evidence to support this view.

Four groups of 20 babies were studied by Drs. Davis and Ruiz. One group was fed by bottle, one by breast, one by cup, and one by mixed methods. Twelve to 18 years later, the subjects (now adolescents) were evaluated on a questionnaire which included requests for information about physical health, height, weight, scholastic achievement, and presence of certain "oral" habits such as eating, drinking, talking, chewing, and smoking. The questionnaire also included three items involving "dependency" strivings, viz., need to be around people, inability to control temper, and submissiveness. Finally, each of the subjects completed a Minnesota Multiphasic Personality Inventory (MMPI).

Extensive analysis of the data obtained did not reveal significant differences among the four groups with respect to physical characteristics, personality type, or academic achievement. No difference with respect to orality or dependency was found between subjects who had sucked as infants and subjects who had been fed by methods that did not allow them to suck. The only significant finding on the MMPI was that cup-fed girls were better adjusted than breast-fed girls; however, this finding must be cross-validated before any inferences can be made. In sum, this investigation provided no evidence that method of feeding during infancy is related to subsequent physical or psychological health.

CHRONIC ALCOHOLISM

This article adds another woe to the growing list of potential problems for the heavy drinker. Heretofore, most physicians thought only of the liver as a target area for alcohol.

Continued

Recently heart disease and hypoglycemia were recognized, and now an acute muscular syndrome joins the ranks. The syndrome is made up of muscle aches, cramps, and weakness with variable constellations of laboratory findings—myoglobin and related proteins in the urine; increased serum creatine phosphokinase activity; poor lactic acid response to ischemic exercise; and variable muscle phosphanylase activity. The authors made their observations on 21 patients within 48 hours after acute intoxication. They speculate on the pathogenesis, but conclude their paper by saying that the only established facts are that the syndrome is brought on by heavy drink and is reversed when drinking stops.

SPHINCTEROTOMY

A circular band of muscle fibers extending for more than five millimeters longitudinally along the common duct, at the level of the outer fenestra where the duct enters the duodenal wall, is the most important element of the sphincter of Oddi. Sphincterotomy is required occasionally in acute cholecystitis or in patients who have been known to have gallstones for many years, and also when a patient has a post-cholecystectomy syndrome characterized by recurring attacks of pain. The third class of patients includes those who have attacks of recurring pancreatitis associated with biliary tract disease.

The technique of sphincterotomy is described, and it is pointed out that a ureteral catheter is passed preferably through the cystic duct and through the ampulla. A mosquito forceps is then placed through the opening of the sphincter alongside the catheter and the crushed tissue under the mosquito forceps is excised, removing a triangular wedge which includes the choledochal sphincter. On occasions the pancreatic duct can be visualized entering from the left and posteriorly.

Partington obtained good results in approximately 70 percent, fair in 20 percent, and poor results in the remainder. He pointed out that drainage of the common duct is not necessary if the duct has not been opened and if the common duct has been catheterized through the cystic duct.

ENDOMETRIAL CANCER

The 610 patients reported were treated for 27 different modalities of cancer. Five hundred seven patients were followed five years or more, with a crude survival rate of 54%. Two hundred twelve patients were treated with preliminary radium followed by hysterectomy, with a five-year survival of 68%; 152 were treated with primary hysterectomy, with a five-year survival rate of 65%. This treatment has been used with increasing frequency in the past decade. The prognosis depends on whether the cancer is confined to the uterus or has gone beyond it. During the 40 years covered by the study, the incidence of cases with disease limited to the uterus has increased from 40% to 70%. The mean age of the patients was 52 years for stage 0 (limited to endometrium) and 59 years for stage 4 (cases with carcinomatosis). The incidence of vaginal metastases had no relation to the use of radium; it was highest in patients with advanced disease. A second malignancy developed in 14 cases.

INFERIOR VENA CAVA

This report shatters the long held belief that inferior vena cava ligation stops pulmonary emboli arising in the legs. In a two and a half year period the authors were confronted with nine patients with recurrent emboli after vena cava ligation. All were documented clinically, and two were confirmed at autopsy. All had typical signs and symptoms of pulmonary embolism; seven had elevated lactic dehydrogenase levels; and all had some form of x-ray confirmation. The group of nine patients represented a recurrence rate of 20 per cent — far above the rate quoted in the literature. Large collateral veins were demonstrated by venography in six patients. These veins were probably the pathway for the recurrent emboli.

RHINOPHYMA

The terminology, history, pathology, etiology, and treatment of rhinophyma are discussed. Rhinophyma is rare in women. Of 57 patients with rhinophyma 14 were operated on, 2 under local anesthesia and 12 under general anesthesia. Since 2 of the patients were brothers, attention was attracted to the hereditary aspect. Family histories of the other patients, however, were completely negative for rhinophyma. The authors used the simple shaving technique and think that this procedure is safe if care is taken not to expose the underlying cartilages. Subsequent retraction of scar tissue was no problem and if the deformity is not overcorrected during the surgical procedure, the formation of scar tissue will not adversely influence the final result. It is important to bevel the incision around the rhinophyma to avoid a step effect. With this technique, healing occurred smoothly and the transition between the re-epithelialized area and the normal nasal skin became almost undetectable. The entire epithelialization process took about 2 or 3 weeks, at which time the shaved area was covered with a smooth and delicate epithelium. Tissue culture studies of rhinophymatous tissue showed a marked reduction in the onset and speed of growth as compared with normal skin of the same patients. While acne rosacea, seborrhea, and adenoid cystic epithelioma may cause humps and enlargement of the nose, they are considered to be separate and distinct disease processes and are not actual precursors of true rhinophyma.

GASTRIC POLYPS

Gastric polyps, either solitary or multiple, have been studied in 14 cases. Three of these were benign, 2 denoted some cellular atypia, 6 revealed carcinoma "in situ," and 3 were invading carcinomas. All but one of the transformed polyps were over 1.5 cm. in diameter. The association with other primary carcinoma was encountered in two patients, and one patient had the association of benign polyposis with pernicious anemia. If only the glandular polyps are included in the material one gains the impression that gastric polyps are of important interest as a precancerous lesion and should be dealt with as such.

NEWER TREATMENTS OF STROKE

Cerebral infarction due to occlusive vascular disease is being studied enthusiastically with the idea of providing benefit to patients who in the past were considered to be beyond effective medical help.

Anticoagulants, fibrinolytic agents and surgical excision of occlusive lesions in the extra-cranial arteries are the most commonly used procedures in this new approach to the problem of stroke.

Among 73 patients, most of whom were in the sixth decade, there was an operative mortality of 8%, and there was an incidence of complication of 19%. The complications included local hemorrhage, local infection, transient hypoglossal nerve palsy, permanent Horner's syndrome, and postoperative hypotension.

In the mortality figures, it was considered that technical errors, which can now be avoided, were a major factor. For the postoperative thrombosis or embolization that occurred after the operation, it was considered that if cerebral protection can be provided during the clamping of the artery, better results are predictable.

It was suggested that embolization can be minimized by the use of a distal occluding clamp prior to mobilization of the carotid vessel. It was also suggested that the venous oxygen saturation demonstrating the adequacy of cerebral circulation should be practiced meticulously in order to minimize if not completely banish the need for a shunt procedure, which in itself increases the danger of postoperative thrombosis. The use of oxygen-rich gas mixtures, hypercarbia, and system hypertension to 180 mm. of mercury is urged.

Pediatrics

I am an optimist in my philosophy of life. I became a pediatrician because pediatrics is full of interesting and important problems. It has the added advantage of bringing you in contact with youth and its stimulation. Furthermore, children are our future. I have never regretted the step. The more I have studied the child the more I have admired nature for accomplishing this miracle of creation. — Bela Schick

Special Article

Noninvasive Neurological Changes in Systemic Malignancy*

ETER JAMES DYCK, M.D.**
ochester, Minnesota

THIS IS A review of some of the neurological syndromes found to be associated with cancer but in which there is no actual invasion or compression by the tumor of the central nervous system, of peripheral nerves, or of muscle. These neurologic syndromes have only recently been recognized by neurologists, and much of the material in this review comes from a recent monograph edited by Lord Brain and Norris.[1]

Various neurological syndromes have been known to occur in association with malignant lesions; for example, in his textbook, Oppenheim[2] mentioned carcinomatous cachexia as a cause of neuritis. Others have reported cases in which there was both a neurological condition and cancer. In 1929 Casper[3] described a patient who had subacute cerebellar degeneration with carcinoma, and Parker and Kernohan[4] described a similar case in 1933. In 1948 Denny-Brown[5] stated that the coincidence of development of bronchogenic carcinoma in two similar cases of a sensory neuropathy and muscle degeneration "was more than a chance association." According to Lennox and Prichard[6] these cases had been initially reported to the Royal Society of Medicine by Kendall and, subsequently, also by Denny-Brown. Along with a third case, they were also included in Wyburn-Mason's[7] paper in 1948.

Since these early reports, British investigators have reported cases of carcinoma associated with such neurological syndromes as peripheral neuritis, a myasthenia gravis-like illness, and subacute cerebellar degeneration. Lennox and Prichard[6] reviewed the records of 299 consecutive patients with bronchogenic carcinoma at the Hammersmith Hospital and found five who had, in addition, a peripheral neuritis. This incidence, 1.7%, was considerably higher than

the incidence of neuritis in the general admissions to the hospital. These authors recognized that their argument for an association between these two conditions rested on a statistical basis. In 1956 Lambert and coworkers[8] described a group of patients who had an unusual and distinctive defect of neuromuscular transmission different from myasthenia gravis, and most of whom also had small-cell bronchogenic carcinoma. In 1958 Aström and co-workers[9] described progressive multifocal leukoencephalopathy.*

The interest in the association between certain neurological syndromes and various carcinomas lies not only in the proper identification of these disorders but, more important, in the information it may give regarding the relationship between the carcinoma and the neurological syndrome. The strongest case for a significant relationship can be made when the neurological syndrome itself is distinctive and is always associated in time with one kind of malignancy. Unfortunately, none of the neurological syndromes associated with carcinoma fulfill these criteria completely. The three that seem to come closest are the sensory neuropathy of carcinoma, the myasthenic syndrome of Lambert, Eaton, and Rooke,[8] and the progressive multifocal leukoencephalopathy of Aström, Mancall, and Richardson.[9] It should be pointed out that two of these neurological syndromes cannot be identified with certainty clinically but depend on electrophysiological tests in the case of the myasthenic syndrome and on pathological examination of the brain in the case of the progressive multifocal leukoencephalopathy.

The case for a significant association between other neurological syndromes and cancer seems to be less substantial. The syndromes are in themselves not as distinctive, being seen most frequently associated with diseases other than malignancy. The malignancies with which they are associated are of many types, and there is no correlation between severity of the neurological syndrome and the severity and extent of the malignancy. In these cases the argument for a significant relationship rests mainly on the higher frequency of association between neurological syndrome and malignancy.

---

*See Test Your Word Score Page 1573.

Progressive Multifocal Leukoencephalopathy

This condition is discussed first because the criteria, proposed earlier, for establishing an association between malignancy and a neurological syndrome are reasonably well satisfied here, and there is a possible explanation for the mechanism of production of the neurological syndrome.

Neuropathological Findings

The diagnosis of this condition is based on neuropathological findings, as shown in Figure 1. Note the demyelinated white and adjacent gray matter of this coronal section of the cerebral hemisphere, with adjacent smaller areas which are also demyelinated. Occasionally, similar changes have been noted in the spinal cord. Richardson[10] thought that the appearance of the lesion and the clinically progressive course suggest that these smaller lesions enlarge and coalesce. The myelin breakdown is sudanophilic with preservation of the axis cylinders. Striking features are the gigantic astrocytes and the unequivocal multipolar mitotic figures (Figure 2).

Clinical Features

This distinctive neuropathological picture occurs in association with lymphomas in more than one half of all cases (Table). In the remainder of the cases it occurs in association with chronic disease. Furthermore, it appears to be a disease of late adult life. The clinical features are not distinctive except for the rapidly progressive course, of three to six months. Hemiparesis progressing to quadriparesis, visual field defects or blindness, aphasia, ataxia, dementia, confusional state, and, finally, coma are said to be typical manifestations. Certainly, when such a neurological picture is noted in association with lymphoma, the correct diagnosis should be strongly suspected.

Richardson[10] postulated that the most likely explanation of this neurological syndrome is a virus infection. (There is a higher

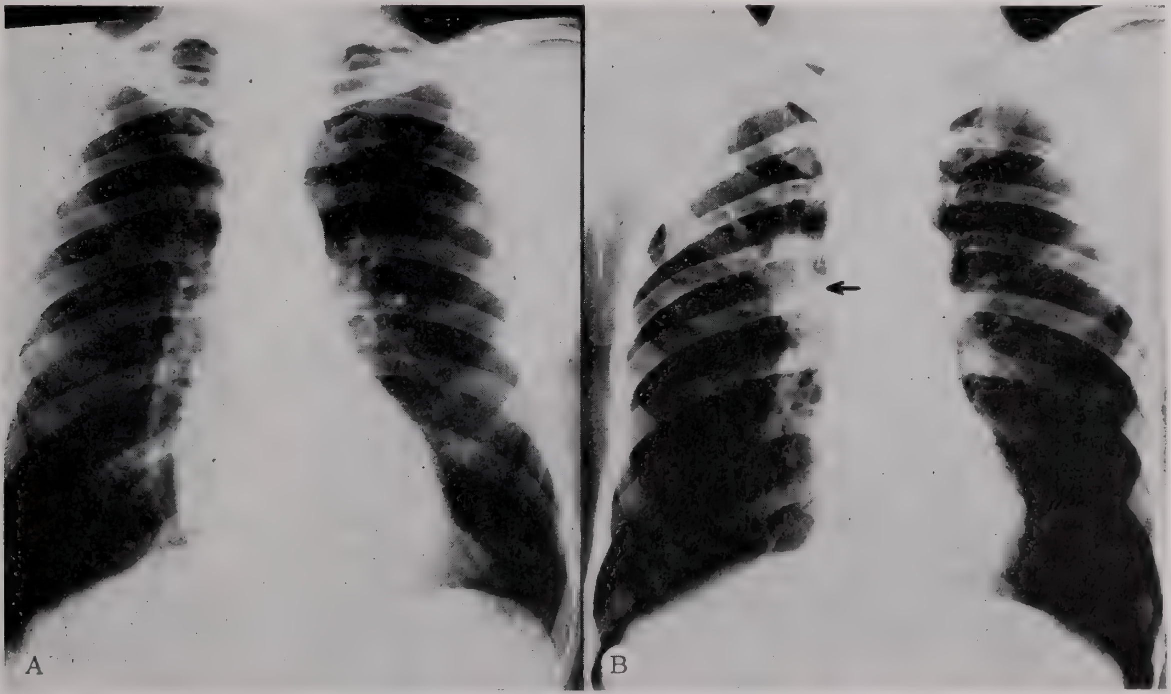

Fig. 3 — *(a)* Normal thoracic roentgenogram 22 months after the onset of the neuropathy. *(b)* Mass in the right hilum apparent 3½ years after the onset of symptoms. (From Dyck, P. J., Bailey, A. A., and Olszewski, Jerzy: Carcinomatous Neuromyopathy: A Case of Sensory Neuropathy and Myopathy with Onset Three and One-half Years Before Clinical Recognition of the Bronchogenic Carcinoma. Canad Med Ass J 79:914, 1958. By permission of the publisher, Canadian Medical Association Journal.)

Continued

incidence of herpes zoster infection [also viral] associated with lymphomas.) ZuRhein and Chou[11] recently reported having seen virus-like particles in oligodendroglial cells from small demyelinated regions in a case considered to be progressive multifocal leukoencephalopathy. The presence of these virus particles in demyelinated regions of the brain in this condition raises the possibility that this demyelinating disorder may be caused by a viral infection. If a virus can be grown from brains in cases of progressive multifocal leukoencephalopathy and if the virus can be transmitted with the production of similar lesions, the viral etiology will be established. However, it is possible that such a virus might not grow except in brain tissue which, biochemically or otherwise, has been altered by the presence of chronic disease such as lymphoma. A baffling point about these cases is the fact that, contrary to what one expects in a viral encephalitis, there is no pleocytosis reflected in the spinal fluid and the time course is different.

Myasthenic Syndrome and Lung Cancer

Lambert and co-workers[8] have defined this syndrome. Of 30 patients who fulfilled the electrophysiological criteria, 22 had, then or subsequently, intrathoracic tumors. Seventeen of 19 bronchogenic carcinomas were of the small cell type — the criteria of a unique syndrome invariably associated with a specific malignancy being almost fulfilled. Furthermore, improvement of the neurological state in association with apparent successful treatment of the bronchogenic tumor has been noted in some of the cases.

†One patient had both sarcoidosis and pulmonary tuberculosis.

Clinical Features

The clinical features in themselves have not been distinctive enough to permit a firm diagnosis in most cases. The syndrome occurs mainly in men more than 40 years of age; weakness and fatigability are the most common initial symptoms. In contrast to myasthenia gravis, the bulbar muscles are less affected than are proximal limb muscles, and thus diplopia, weakness of facial muscles, and chewing weakness are less dominant symptoms in the myasthenic syndrome. Dryness of the mouth was a presenting symptom in one half of the patients. Peripheral paresthesia and loss of potentia were also found in approximately one half of the patients.

Electrophysiological Tests

On clinical testing of muscle strength it was possible to detect, in some of these patients, the unusually slow buildup of the muscle contraction, developing during one to several seconds. Tendon reflexes tended to be absent or diminished, especially in the lower extremities. Two salient features of the distinctive electrophysiological tests are:

1. The amplitude of the action potential from muscle and the amplitude of the muscle twitch from a single supramaximal stimulus of the appropriate nerve are unusually small, although the voluntary contraction of the muscle is almost normal in strength.
2. At slow rates of repetitive stimulation (three per second) a decrease, from an already low amplitude, in the action potential occurs. However, at rapid rates (at 50 per second) marked facilitation occurs. This facilitation explains the fact that voluntary strength is normal or almost so, but the twitch response from a single electrical stimulus is very low.

Lambert and co-workers[8] thought that this syndrome is best explained by a defect at the neuromuscular junction and, furthermore, that it is distinct from myasthenia gravis both by clinical and by electromyographic features. They found that quanidine hydrochloride has been more effective than anticholinesterases in the management of these cases.

Carcinomatous Sensory Neuropathy

Approximately 10 cases of sensory neuropathy with degeneration of dorsal root ganglion cells have now been described. Dr. William Karnes,[12] a neurologist at the Mayo Clinic, has recently reviewed these and has found a new case. He has not found any reports of this syndrome associated with any condition except bronchogenic carcinoma. From the clinical point of view, these cases have been distinctive enough so that, in some of them, the finding of a bronchogenic carcinoma was anticipated on the basis of the neurological state. It should be pointed out that other varieties of sensory neuropathy, such as familial, diabetic, amyloid, arsenic, and unexplained neuropathies, can simulate this neuropathy; but in these cases the family history, the evident diabetes, the increased excretion of arsenic, or the presence of deposits of amyloid in the dorsal ganglia permits differentiation. In addition, the course of these other sensory neuropathies tends to be much more prolonged.

History and Pathological Findings

The history and pathological alterations of this condition are illustrated by a case (Case 1) reported in 1958 in collaboration with Bailey and Olszewski.[13]

A 49-year-old farmer had progressive, prickling, numbness of his feet and hands for three and one-half years before the first evidence of bronchogenic carcinoma was recognized roentgenographically. Thoracic roentgenograms taken 22 months after the onset of symptoms of the sensory neuropathy did not show the carcinoma (Figure 3*a*), although its presence was anticipated on the basis of the neurological syndrome. Three and one-half years after the onset of the sensory neuropathy, the patient was in a cachectic state and had lost 30 pounds; the thoracic roentgenogram now showed the hilar tumor (Figure 3*b*). He had severe distal numbness and shooting pains in all extremities and, on examination, generalized muscle weakness and wasting, areflexia, and severe distal sensory loss. Death occurred almost four years after the onset of symptoms of neuropathy. The bronchogenic carcinoma was anaplastic with local extension and metastasis, but no metastatic lesions were found in central or peripheral nerves. Striking histologic alterations were found in the posterior root ganglia: The ganglion cells were degenerated and replaced by the cap cells forming the residual nodules of Nageotte (Figure 4), and the posterior columns and the dorsal root distal to the ganglia were also demyelinated (Figure 5).

Continued

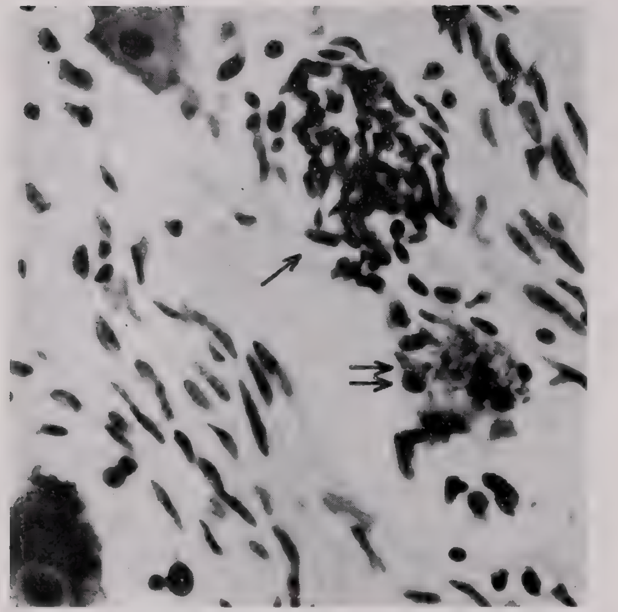

Fig. 4 — Dorsal root ganglia with residual nodules of Nageotte *(single arrow)* and early stages of neuronal degeneration *(pair of arrows)*. (Gomori iron stain, x120.) (From Dyck, P. J., Bailey, A. A., and Olszewski, Jerzy: Carcinomatous Neuromyopathy: A Case of Sensory Neuropathy and Myopathy with Onset Three and One-half Years Before Clinical Recognition of the Bronchogenic Carcinoma. Canad Med Ass J 79:915, 1958. By permission of the publisher, Canadian Medical Association Journal.)

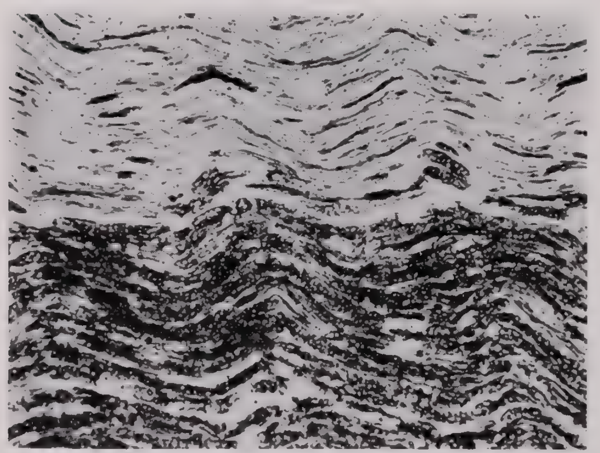

Fig. 5 — T3 spinal nerve just after the junction of fibers from the spinal ganglia, in upper half of picture, with the anterior root, in lower half of the picture. Note the demyelinization of the dorsal root fibers. (Heidenhain stain; x120.) (From Dyck, P. J., Bailey, A. A., and Olszewski, Jerzy: Carcinomatous Neuromyopathy: A Case of Sensory Neuropathy and Myopathy with Onset Three and One-half Years Before Clinical Recognition of the Bronchogenic Carcinoma. Canad Med Ass J 79:915, 1958. By permission of the publisher, Canadian Medical Association Journal.)

Denny-Brown[5] thought that the primary involvement in this condition is in the dorsal root ganglion and that the posterior column and sensory root demyelinization are secondary.

Carcinomatous Polio-Encephalopathy

A carcinomatous polio-encephalopathy has been described as being characterized by a rapid deterioration in memory, sometimes associated with cerebellar ataxia. In another group of cases the rapidly progressive cerebellar ataxia, sometimes associated with lesser mental changes and brain-stem and long-tract signs, is predominant. In still another group, the main changes are in the brain stem. In the cerebellar group the points which distinguish it from other causes of progressive cerebellar ataxia are: (1) the patient is older than the usual patient at the onset of multiple sclerosis, and (2) the progression of the disability is much more swift than is usually seen in degenerate cerebellar disorders.

Carcinomatous ALS

Norris and Engel[14] described a carcinomatous amyotrophic lateral sclerosis because they found a significant carcinoma in 10% of 130 consecutive cases of amyotrophic lateral sclerosis. However, Mulder[15] did not find any significant malignancy in the 100 consecutive patients with amyotrophic lateral sclerosis whom he saw in 1954 at the Mayo Clinic and whom he followed until their death (in all but a few cases). I have briefly reviewed the coded diagnosis in the first 200 consecutive cases (from 1949 to 1954) diagnosed as amyotrophic lateral sclerosis by the neurologists at the Mayo Clinic. Only two of these cases included recognized, significant tumors, and in both cases the tumors seemed to be unrelated to the amyotrophic lateral sclerosis in time, having been treated successfully and without evidence of recurrence — by radical mastectomy in one case and resection of sigmoid carcinoma with end-to-end anastomosis in the other — four years before the onset of symptoms of amyotrophic lateral sclerosis.

This striking difference in incidence of significant malignancy in patients with amyotrophic lateral sclerosis is hard to explain. It may be related in part to differences between the patients referred to the National Institutes of Health and the University of Rochester and those seen at the Mayo Clinic. Another difference may be in the criteria used to diagnose amyotrophic lateral sclerosis — for example, Case 2 of Norris and Engel would probably not have been included as an amyotrophic lateral sclerosis case at the Mayo Clinic. Finally, another difference may be in the criteria used for the diagnosis of significant malignancy; in Norris and Engel's Cases 7, 9, and 13 no evidence had been found of recurrence of an earlier malignant lesion in spite of intensive investigation, and in their Case 11 even postmorten examination did not disclose it. Therefore, the association between amyotrophic lateral sclerosis and significant malignancy does not seem to be a closed question.

Some difference of opinion also exists regarding the incidence of malignancy in polymyositis and dermatomyositis. Christiansen and co-workers[16] reviewed 270 cases of dermatomyositis at the Mayo Clinic and found approximately 7% with an associated malignancy. In a group of 104 patients with polymyositis or dermatomyositis, Mulder and co-workers[17] found an incidence of malignancy of almost 7%. In striking contrast to these data are those of Shy[18] who found an over-all incidence of carcinoma of 18 to 30% in myopathies of late onset. Among patients more than 50 years of age, the incidence was 39%. The association was even more striking in men, with carcinoma found in 71% of cases.

Mechanisms

Nutritional

Historically, it was thought that cachexia explained the neuropathy of carcinoma. As pointed out by Denny-Brown,[5] a posterior ganglion degeneration does occur in experimental animals deficient in pantothenic acid. However, administration of vitamin supplements to subsequent patients with carcinomatous sensory neuropathy was of no benefit. It is still possible that some of the neurological syndromes are the result of a deficiency of a vitamin, amino acid, or other essential biochemical factor.

Viral Infection

Another mechanism may be the coexistence of a viral infection — for example, herpes zoster infection in the lymphomas and possibly a glial virus in progressive multifocal leukoencephalopathy. Another explanation of the relationship between neurological syndrome and carcinoma might be the hypothesis that an environmental carcinogen produces both. Prehn[19] has argued that it is even possible that a carcinogen might release antigens which then precipitate auto-immune disease. Wilkinson[20] found organ-specific complement-fixing antibodies to antigens in unmyelinated dorsal roots and central nervous system gray matter in a case of carcinomatous sensory neuropathy. This then may be the counterpart of experimental allergic encephalitis and experimental allergic neuritis seen in the experimental animal.

Toxic Substance

There is also the possibility that the neurological symptoms are caused by a toxic substance produced by tumors. Recently, several cases have been described in which a tumor appeared to be responsible for the excretion of excessive amounts of porphyrins. Since marked central and peripheral nervous system derangements are associated with another well-known condition in which there is excessive porphyrin excretion — intermittent porphyria — this mechanism should be kept in mind. Finally, the medications and radiation treatments used may themselves be toxic to the normal nervous system.

Summary

This review lists and discusses some of the neurological disorders found to be associated with malignant lesions but not due to actual invasion of nerve tissue by tumor. The strongest case for a significant relationship between a neurological disorder and a ma-

Continued

lignant lesion occurs when the neurological state is distinctive and is always associated in time with one kind of malignant lesion. Three syndromes come close to fulfilling these criteria: sensory neuropathy, myasthenic syndrome, and progressive multifocal leukoencephalopathy. With polio-encephalopathy, polymyositis and dermatomyositis, and amyotrophic lateral sclerosis, the association with carcinoma is less striking. These neurological syndromes are most frequently seen unassociated with malignant lesions and, when associated with malignant lesions, the lesions may be of many types. Finally, the high incidence of carcinoma in patients with amyotrophic lateral sclerosis reported by Norris and Engel has not been confirmed in this report.

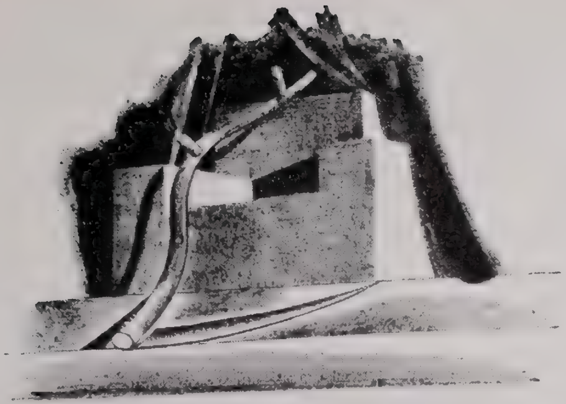
Security

You cannot bring about prosperity by discouraging thrift. You cannot strengthen the weak by weakening the strong. You cannot help the earner by pulling down the wage payer. You cannot further the brotherhood of man by encouraging class hatred. You cannot help the poor by discouraging the rich. You cannot establish sound security on borrowed money. You cannot keep out of trouble by spending more than you earn. You cannot build character and courage by taking away man's initiative and independence. You cannot help men permanently by doing for them what they could and should do for themselves. — Abraham Lincoln

---

The only competition worthy of a wise man is with himself. — Washington Allston



In Memoriam

To neglect, at any time, preparation for death, is to sleep on our post at a siege; to omit it in old age, is to sleep at an attack. — Johnson

LEROY M. EKSTRAND, M.D.

Dr. Leroy M. Ekstrand, 50, member of the Wabasha Community Clinic staff, died August 17. He had practiced medicine in Wabasha since 1946. Born in Waukegan, Illinois, Dr. Ekstrand was a graduate of the University of Illinois School of Medicine.

He was a member of the Wabasha County Medical Society, American Medical Association, Minnesota State Medical Association, American Academy of General Practitioners and American Legion Post 50.

He is survived by his wife and five sons.

JOHN J. CATLIN, M.D.

Dr. John J. Catlin, 85, former Buffalo physician, died August 20 in Macomb, Illinois. Born in Delano, he obtained his medical degree at the University of Minnesota.

Dr. Catlin was a former officer of the Wright County Medical Society and a member of the American Medical Association. He was a life and 50 Club member of the Minnesota State Medical Association.

He is survived by his wife, four daughters and a son, Dr. Theodore J. Catlin of Buffalo.

S. MARX WHITE, M.D.

Dr. S. Marx White, 93, Minneapolis heart and tuberculosis specialist and public health official, died August 30. Born in Hokah, Minnesota, Dr. White received his medical degree at the Northwestern University Medical School in Chicago.

He came to the University of Minnesota as a pathology instructor in 1898 and after 44 years of teaching at the school, was made professor emeritus.

A cofounder of the Nicollet Clinic in Minneapolis, Dr. White had been a member of the Board of Regents of the American College of Physicians, serving as national president from 1931 to 1932. He founded and directed the Glen Lake Tuberculosis Sanatorium and had been director of the Hennepin County Tuberculosis Association. In 1951 he received the Distinguished Community Service Award of the Community Chest and an award from the Junior Chamber of Commerce.

He was a member of the Hennepin County Medical Society and American Medical Association and a life and 50 Club member of the Minnesota State Medical Association.

He is survived by two daughters and a son, Dr. Asher A. White of Minneapolis.

ALFRED T. BAKER, M.D.

Dr. Alfred T. Baker, 82, Minneapolis physician, died September 2. Born in Ida Grove, Iowa, he graduated from the Chicago College of Medicine and Surgery and received his B.S. and M.D. degrees from the University of Minnesota. Dr. Baker was one of the original six members of the closed staff of Eitel Hospital in Minneapolis. He also was a former chief-of-staff at Eitel Hospital.

He was a member of the Hennepin County Medical Society and American Medical Association and a life and 50 Club member of the Minnesota State Medical Association. In 1954 he retired from private practice because of illness.

He is survived by his wife and a daughter.

SYMPOSIUM ON ADOLESCENCE

NEW ORLEANS, LOUISIANA **DECEMBER 1-3, 1966**

Approved for 15 hours credit by the American Academy of General Practice
Sponsored by the
DIVISION OF PSYCHIATRY and COMMUNITY MENTAL HEALTH CENTER
OF TOURO INFIRMARY
supported by a National Institute of Mental Health Grant

GUEST LECTURERS INCLUDE:

Dana Farnsworth, M.D., Director of Student Health Services at Harvard University, Cambridge, Mass.
Irvin Kraft, M.D., Professor of Child Psychiatry at Baylor Medical School, Houston, Tex.
John Schimel, M.D., Associate Director of William Alanson White Institute of Psychiatry, Psychoanalysis and Psychology, New York, N. Y.
George Tarjan, M.D., Professor of Psychiatry and Program Director of Mental Retardation Project at University of California in Los Angeles, Calif.
Carroll Witten, M.D., President-Elect of American Academy of General Practice, Louisville, Ky.

AMONG TOPICS TO BE DISCUSSED:

"The Physician's Role in Mental Retardation"
"Parents of Problem Children"
"Handling of Adolescents by General Practitioners"
"Sexual Morality — A College Dilemma"
"Drugs in the Treatment of Children and Adolescents"
"Learning Problems of the Adolescent"
"Adolescence and Social Mores"
"Talking About Sex with Adolescents"
"Religious — Psychological Conflicts"

Symposium will be held at the Fontainebleau Motor Hotel, 4040 Tulane Ave. Early hotel reservations are recommended.

Gene L. Usdin, M.D.
Director of Psychiatric Services
Touro Infirmary
1400 Foucher Street
New Orleans, Louisiana 70115

Enclosed is my registration fee of $20 for the SYMPOSIUM ON ADOLESCENCE to be given December 1-3, 1966 at the Fontainbleau Motor Hotel. (Checks should be made payable to Touro Infirmary.)

Who will do it? The colleges of course! They educate leaders to meet the challenges America faces in business, science, government, everyday living.

But the colleges need help. Quality education is expensive, and more Americans require a college education.

College is America's best friend. Give to the college of your choice —keep our leaders coming.

Published as a public service in cooperation with The Advertising Council and the Council for Financial Aid to Education.

Cinderella Story

It's a modern Cinderella story. Almost every woman who develops uterine cancer can be cured—*if* the cancer is discovered early and treated promptly. The "Pap" test—a simple, painless examination which your doctor can make in his office—can detect uterine cancer in this early, curable stage.

Make the "Pap" test part of your annual health checkup. Fight cancer with a checkup—and a check, sent to CANCER, c/o Postmaster.

(allobarbital and acetaminophen CIBA)

Indications: For relief of pain and discomfort of simple headache; neuralgia, myalgia, and musculoskeletal pain; dysmenorrhea; bursitis; sinusitis; fibrositis. Also indicated to reduce fever and to relieve discomfort due to respiratory infections, influenza, and other febrile conditions.

Contraindication: Not recommended during pregnancy.

Caution: May be habit-forming. Do not use in patients sensitive to barbiturates or in those with moderate to severe hepatic disease.

Side Effects: Nausea, transitory dizziness, rash. Overdosage of allobarbital produces symptoms typical of acute barbiturate excess.

Dosage: *Adults:* 1 or 2 tablets every 4 hours. Not to exceed 8 tablets in 24 hours. *Children 6 to 12:* ½ to 1 tablet every 4 hours. Not to exceed 4 tablets in 24 hours.

Supplied: *Tablets* (white, scored), each containing 15 mg allobarbital and 300 mg acetaminophen; units of 3 bottles of 30.

For your convenience — prescription-size bottle of 30.

CIBA Pharmaceutical Company, Summit, N.J.

Partnership Life Insurance

Frequently the question arises in medical partnerships as to whether the purchase of a partner's interest upon his death should be funded by the purchase of insurance on the lives of the partners. Briefly, this is accomplished by a system of cross-insurance whereby a policy is carried on each partner's life. Each policy on a partner's life is owned by all the other partners who are also beneficiaries of that policy. For example, in the "A, B, C" partnership, "A" and "B" own a policy on "C"; "A" and "C" own a policy on "B"; and "B" and "C" own a policy on "A." Due to varying ages and rates, the insurance premiums are generally totaled and charged to the partners on an equal basis. These premiums represent personal nondeductible expense to the partners.

Since the policy on a partner's life is owned by the other partners, this insurance is not included in his estate in case of death. The proceeds of a policy, in case of death, are tax free to the beneficiary partners.

What are some of the advantages of such a plan?

1. It provides immediately available cash upon the death of a partner for liquidation of his capital interest.
2. It eliminates any risk of a partner's estate not getting its money from the remaining partners.
3. It eliminates any financial burden on the partners in the case of death of one or two members and it insures the continuation of the partnership. Often without such insurance, it is necessary to liquidate the partnership in order to pay off a deceased member's interest.

The major disadvantages are:

1. Each partner finances the liquidation of his own capital account indirectly by paying his pro rata share of the cost of the insurance. This benefits his partners but not his own family.
2. Advanced age and insurability often make the cost of such an insurance program extremely high.
3. For partners who are financially independent, this may represent an unnecessary expenditure.

What then is the best approach to determining whether or not a partnership should purchase life insurance on its members?

1. A determination should be made of just what the capital investment is in a partnership and whether or not this investment is adequate to necessitate an insurance program. In many manufacturing and retail firms the capital investment is extremely high and represents all the assets of the partners. This is not generally true of professional partnerships.
2. A review should be made of ages, insurability and financial status of each partner involved. This will reveal both the cost of an insurance plan and, combined with paragraph "1," the need for an insurance plan.
3. A study should be made of workable alternatives to an insurance plan. These include such things as available credit for financing (building, equipment, et cetera), payment of a partner's interest in accounts receivable as collected, and installment payments to an estate in settlement of the remaining capital interest.

As an example of a partnership insurance problem and its solution, let us consider the "A, B and C" partnership. These Doctors own an office building and equipment valued at $54,000 and have accounts receivable of $39,000. The per-man cost of liquidating would be $31,000 in the event of death. Doctor "A" is 57 years of age and independently wealthy. He has a physical condition that would increase his life insurance cost by 20%. Doctor "B" is 41 and could easily borrow funds to purchase his share of a partner's interest. Doctor "C" is 29 and has no resources whatsoever. His maximum credit would be about $5,000.

Here is the solution they chose. Accounts receivable were made self-liquidating; in case of death, they would be frozen and each partner paid his interest as they were collected. In their partnership agreement a clause provides that surviving partners have the option of paying off the deceased partner's interest, either in full or over a period of five years, with minimum payments of $300 per month at 5% interest. As added protection, each doctor has his own credit and resources and the surviving doctors also have a mortgagable building which could provide $25,000-$30,000 purchase money at 5½%.

In this case, we feel that their solution is much more workable than an extremely high-cost insurance plan. In summary, we feel that large life insurance programs *generally* are not necessary for professional partnerships and that the insurance premiums can be used by the doctors with less resources to provide much needed insurance protection for their own families.

Since this is only *generally true*, there are individual exceptions; therefore, an extensive individual study should be made by the partners, their attorneys and their financial advisers before a program of life insurance is adopted. Such a study will determine whether a need exists for partnership life insurance and, if so, how large a program is necessary.

GENERAL PRACTITIONER wanted to join well-established practitioner. New clinic building — 90 miles east of St. Paul — city of 14,000. Early partnership with full hospital facilities. Ideal location. L. W. Picotte, M.D.; Chippewa Falls, Wisconsin.

GENERAL PRACTITIONER: Four-man group desperately needs fifth physician. 3,300 growing rural town with three good industries. 50-bed hospital with 50-bed nursing home attached. Salary first year then full partnership. Contact: R. W. Gustafson, M.D.; Granite Falls, Minnesota.

A THREE MAN GROUP needs a fourth general practitioner in a fast-growing West St. Paul area. Begin with salary and join partnership with full participating advantages. Write: MINNESOTA MEDICINE — 305, 496 Lowry Medical Arts Building, St. Paul 55102.

FOR SALE: Mattern x-ray unit K.V.-60. Good for chest and extremity work. Also an examining table, instrument cabinet, E.K.G., and other equipment. Contact L. A. Whitesell, Jr., M.D. 207 South 1st Street, Buffalo, Minnesota 55313.

EASTERN WISCONSIN CLINIC in rapidly growing community of 40,000 desires board-eligible or certified physicians in pediatrics, obstetrics and gynecology and internal medicine. Well-equipped clinic and excellent hospital facilities. Lake shore location offers ample recreational facilities. Attractive financial plan leading to early full partnership. Full expenses paid for applicants invited to interview. Call or write: F. L. Hildebrand, M.D., Riverside Clinic, Menasha, Wisconsin.

INTERNIST for 20-physician-clinic in prosperous Minnesota city. Salary negotiable first year, then full partnership. East Range Clinic, Virginia, Minnesota.

INTERNIST AND GENERAL PRACTITIONER wanted to join a five-man clinic group in Minneapolis. Complete laboratory and X ray with board roentgenologist. Excellent hospital staff associations. Salary arrangement to start with early partnership. Write: MINNESOTA MEDICINE — 289; 496 Lowry Medical Arts Building; St. Paul, 55102.

OFFICE SPACE now available in busy Bloomington. 713 square feet of new space in building with busy group of G.P.'s, dentist and suburban OB-GYN office. Ideal for ophthalmology, ENT or pediatrics. 8040 Penn Avenue South. 888-9211.

WANTED: young general practitioner to join six-man group consisting of 4 GPs, a general surgeon, and radiologist. College town of 22,000, 30 miles from Twin Cities. Also need LOCUM TENENS in general practice. Contact: Ed Jenkins, Mgr., River Falls Medical Clinic, River Falls, Wisc. Phone 425-5322.

WANTED — Internist, board certified or qualified, to associate with two board certified internists. Ten man multi-specialty group. (Lenont Peterson Clinic, Virginia, Minnesota) — Heart of the expanding taconite industry.

PSYCHIATRIC RESIDENCY POSITIONS AVAILABLE: July, 1967, for three year accredited program PRMP. A dynamically oriented broadly-based well-balanced opportunity for sound training. Meadowbrook Hospital is Nassau County General Hospital and is centrally located in the most desirable and beautiful area in the country. Easy commuting distance to New York City. 2800 inpatient psychiatric admissions per year. 24 hour walk-in clinic, and all psychiatric modalities. Abraham S. Lenzner, M.D., Director, Psychiatric Education, Meadowbrook Hospital, P.O. Box 175, East Meadow, Long Island, New York, 11554.

WANTED: Young internist and pediatrician, board certified or eligible, to join 6-man group consisting of 4 GP's, a general surgeon, and a radiologist. College town of 22,000 only 30 miles from Twin Cities. Salary open with early partnership opportunity. Write or call collect: Ed Jenkins, Mgr., River Falls Medical Clinic, River Falls, Wisc., phone 425-5322.

GENERAL PRACTITIONER, associate, urgently needed. Unopposed practice established 20 years. 32 bed new hospital with additional 20 bed chronic unit. Good anesthesia coverage, lab. facilities. Excellent clinic one block from hospital. Salary with early partnership. Locum tenens also considered. Call collect 218-782-4725 or write Klefstad Clinic, Greenbush, Minnesota.

WANTED: GP to join clinic serving population area of 12,000. City has new hospital, new clinic building, two nursing homes, new Jr-Sr high school, new swimming pool, rich farming area in Red River Valley. Fishing and hunting nearby; metropolitan city close by. Salary open and partnership if interested. Write or call Warren Clinic, Warren, Minnesota 742-6231, area code 218.

LARGE GROUP WITH OFFICES IN TWO CITIES is looking for General Practitioner to add to a two-man general practice clinic. Practice limited only by your abilities and interests with ready consultation from specialty partners in other office located in adjacent city. Full partnership after first year. Write: MINNESOTA MEDICINE — 358; 496 Lowry Medical Arts Building, St. Paul, 55102.

WANTED: PHYSICIAN to associate with two General Practitioners, 30 miles from Twin Cities, salary open, with early partnership. New clinic and hospital. Call 835-3129 or 835-2722, or write Doctors Clinic, Forest Lake, Minnesota.

PHYSICIAN WANTED to take over practice in the future. 7,500 population with increase of 3,000 after 3-M plant expansion. Modern, fully-equipped office with complete diagnostic equipment including X-ray and electric cardiogram. Excellent hospital facilities. Ample room for two or three doctors. Contact: E. W. Lippmann, M.D.; 26 Washington Avenue West; Hutchinson.

GENERAL PRACTITIONER WANTED for small town practice with two other general practitioners. Practice to include surgery and obstetrics within your own capabilities. Eligible for partnership after first year. Write: MINNESOTA MEDICINE — 359; 496 Lowry Medical Arts Building, St. Paul 55102.

FOR RENT—Modern, air-conditioned building readily adaptable for a group of doctors or clinic located near 44th and France in highly desirable Edina-Morningside of Minneapolis. Adjacent parking. Contact owner, Ted Shirley, 926-3460.

WANTED: OB-GYN in well established group in city of 15,000. Good hunting and fishing, we have over 1,000 lakes in county. Excellent hospital and clinic facilities. Write: V. I. Hanson, Business Manager, Park Region Medical Center, Fergus Falls, Minnesota.

PSYCHIATRIC RESIDENCIES—positions available January and July 1967. Fully approved; balanced didactic and clinical program. Three programs from which to choose; three-year program, $8,352 to $9,500; five-year career program, $9,500-$17,184: N.I.M.H. General Practitioner stipends, $12,000. Located in Michigan's Water Winter Wonderland. Contact Dr. Paul Kauffman, Director of Training, Traverse City State Hospital, Traverse City, Michigan. An equal opportunity employer.

DON'T OVERLOOK THIS . . . 3 months' rent free in modern medical clinic—successful location in N.W. suburb of Minneapolis. Come see anytime—36th and Noble Avenue North. Noble Drug, Ju 8-9449, Ben or Lou.

WANTED: a general practitioner—present physician retiring after fifty years. Good community, churches, school, stores and bank. New Hospital. Write: MINNESOTA MEDICINE-360, 496 Lowry Medical Arts Building, St. Paul.

LOCUM TENENS for January and February or at least January 15 through February 15. Southeastern Minnesota. $1500 stipend per month. Write: MINNESOTA MEDICINE-363, 496 Lowry Medical Arts Bldg., St. Paul 55102.

AVAILABLE SOON: Fascinating General Practice Partnership for sale in pleasant central California community just two hours from the ocean on high Sierras. Gross over $160,000 although each partner off 30% of the time in the past six years. Excellent duck, pheasant and deer hunting nearby. Profitable hospital laboratory and X-ray service included. Office conveniently located in hospital with open staff. Homes available if desired. Also, lake and ski cabin in North Shore Lake Tahoe Area. Terms negotiable near fair value. Write: MINNESOTA MEDICINE — 362; 496 Lowry Medical Arts Building, St. Paul 55102.

WANTED: G.P. or Internist willing to do some G.P. Twin-towns totalling 12,000, Western Minnesota Group Now three G.P.'s and one FRCS surgeon. Modern clinic building with eleven assistants. X-ray and minor laboratory. 125-bed accredited hospital. Rotating calls one night a week and every fifth week-end. Hunting, fishing, golfing available. Initial salary $1500 per month. Opportunity for partnership in one or two years. Apply: C. W. Jacobson, M.D., Breckenridge, Minnesota.

GENERAL PRACTITIONER WANTED to associate with solo practitioner currently doing over $100 M annual volume. Guaranteed minimum salary, plus bonus. Central Minnesota Lake Region. Write: MINNESOTA MEDICINE-364, 496 Lowry Medical Arts Building, St. Paul 55102.

THREE MAN group in North West Wisconsin Resort, State Conservation and Retirement Area needs two more physicians adequately to serve their practice. Facilities offered are three-room physician suites, X-ray and lab under AMT technician, RN-only nursing personnel. New accredited thirty-two bed hospital and forty-six bed nursing home. Deer and duck hunting, fishing within five minutes of town. Internist most needed; generalists welcomed. Will meet any reasonable salary request. Partnership after one year. Write: MINNESOTA MEDICINE-365, 496 Lowry Medical Arts Building, St. Paul 55102.

RESIDENTS IN PSYCHIATRY — Opening for January 1, 1967 and July 1, 1967. Stipend $11,400 for physicians just completing internship. Federal stipend available to physicians with 4 years non-psychiatric training or experience following internship amounting to $12,000 annually with an extra $3600 tax exemption. Graduates of American schools must be eligible for Iowa licensure. Foreign graduates must have ECFWG certificate. Hospital has 450 in-patients, large out-patient dept., children's unit with Board-certified Child Psychiatrist. Eclectic program with emphasis on community and existential psychiatry. Thirteen senior staff members including ten Board certified. Numerous consultants. Authorized for 12 residents. Affiliation with University of Iowa. Enthusiastic and dynamic training and treatment programs that are best understood by a personal visit. Write or call collect: W. C. Brinegar, M.D., Supt., or John Worthington, M.D., Mental Health Institute, Cherokee, Iowa.

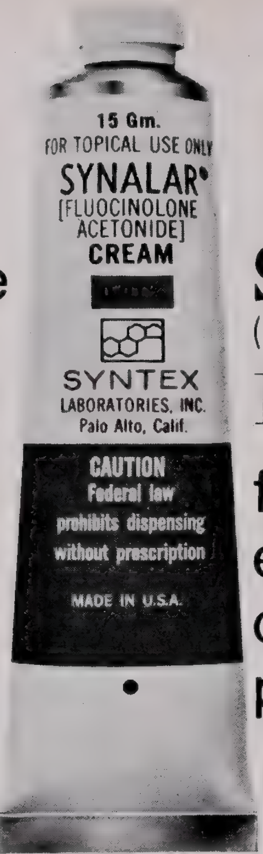
G. P., age 31, two years experience, married with family, would like to relocate, limiting practice to medicine and pediatrics. Write: MINNESOTA MEDICINE — 361; 496 Lowry Medical Arts Bldg., St. Paul 55102.

General practitioner Wanted — Present physician retiring due to illness. New office Building, Call or write Anton Pharmacy, 879 S. Smith Ave., W. St. Paul. Phone 222-5700.

FOR RENT: Space available for surgical subspecialists. Excellent location. Near Unity Hospital, 10 minutes from Mercy. Share space with General & Thoracic Surgeon and 2 interns. Call Mrs. Winkel — 560-1700, Fridley.

PATHOLOGIST — Certified by the American Board of Pathology. Desires location in the Twin Cities area, large or small hospital. Four years experience. All openings considered. Write: MINNESOTA MEDICINE-366, 496 Lowry Medical Arts Building, St. Paul 55102.

new small size



Synalar® 0.01

(fluocinolone acetonide) **cream**

15 Gm.

for even greater economy in office or hospital practice

the superiority topica with the

Now you can prescribe as little or as much Synalar Cream 0.01% as is needed for a particular therapeutic problem in a size that permits the greatest economy for your patient. The new 15 Gm. tube, for example, is best suited for short-term therapy and for small sites. For more extensive body areas prescribe the 45 Gm. tube—a size that's also ideal for your treatment table. And the 120 Gm. jar is most economical for hospital use. Thus, with Synalar Cream 0.01%, you have the superiority of a modern topical corticosteroid shown to be more effective than 1% hydrocortisone[1-3] plus the economy that makes therapy practical for use in more dermatologic conditions, in long-term maintenance, with occlusive dressings in resistant cases, and in extensive area involvement.

Contraindications: Tuberculous, fungal, and most viral lesions of the skin (including herpes simplex, vaccinia, and varicella). Not for ophthalmic use. Contraindicated in individuals with a history of hypersensitivity to any of its components. **Precautions:** 1. *General*—Synalar Cream 0.01% is virtually nonsensitizing and nonirritating. Where severe local infection or systemic infection exists, the use of systemic antibiotics should be considered, based on susceptibility testing. While topical steroids have not been reported to
have an adverse effect on pregnancy, the safety of their use on pregn
females has not absolutely been established. Therefore, they should not
used extensively on pregnant patients, in large amounts, or for prolon
periods of time. 2. *Occlusive dressing method*—With occlusion of extens
areas, systemic absorption of the corticosteroid may occur, and suita
precautions should be taken. Occasional patients may show contact se
tivity to a particular dressing material or adhesive. Miliaria, folliculitis
pyodermas have been seen infrequently with the use of this technique.
development of infection requires appropriate antibacterial therapy and
continuation of the occlusive dressing method. Local atrophy and st
have been reported with protracted occlusive dressing therapy. While les
relapses can be expected to occur in many psoriatic patients, remissi
may persist for several weeks to several months in favorable cases.
patient whose psoriasis is in an active stage, with recent appearance of
lesions, may not be a good candidate and may show early relapse. S
plastic films may be flammable, and due care should be exercised in t
use. Similarly, caution should be employed when such films are used o
left near children to avoid the possibility of accidental suffocation.
Effects: Side effects are not ordinarily encountered with topically app
corticosteroids. As with all drugs, however, a few patients may react
vorably to Synalar under certain conditions. **References:** 1. Cahn, M. M.,

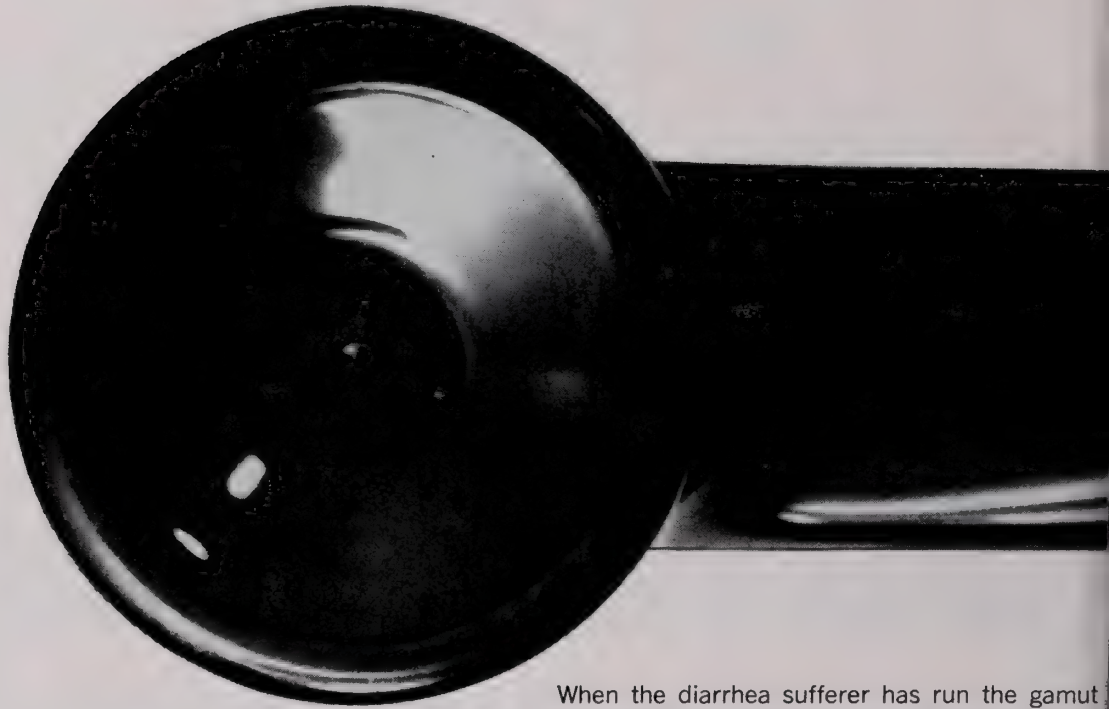
When uncontrolled diarrhea brings a call for help



When the diarrhea sufferer has run the gamut
home remedies without success, pleasant-tasti
CREMOMYCIN can answer the call for help. It can
counted on to consolidate fluid stools, soothe int
tinal inflammation, inhibit enteric pathogens, a
detoxify putrefactive materials — usually withir
few hours.

CREMOMYCIN combines the bacteriostatic agen
succinylsulfathiazole and neomycin, with the
sorbent and protective demulcents, kaolin and p
tin, for comprehensive control of diarrhea.

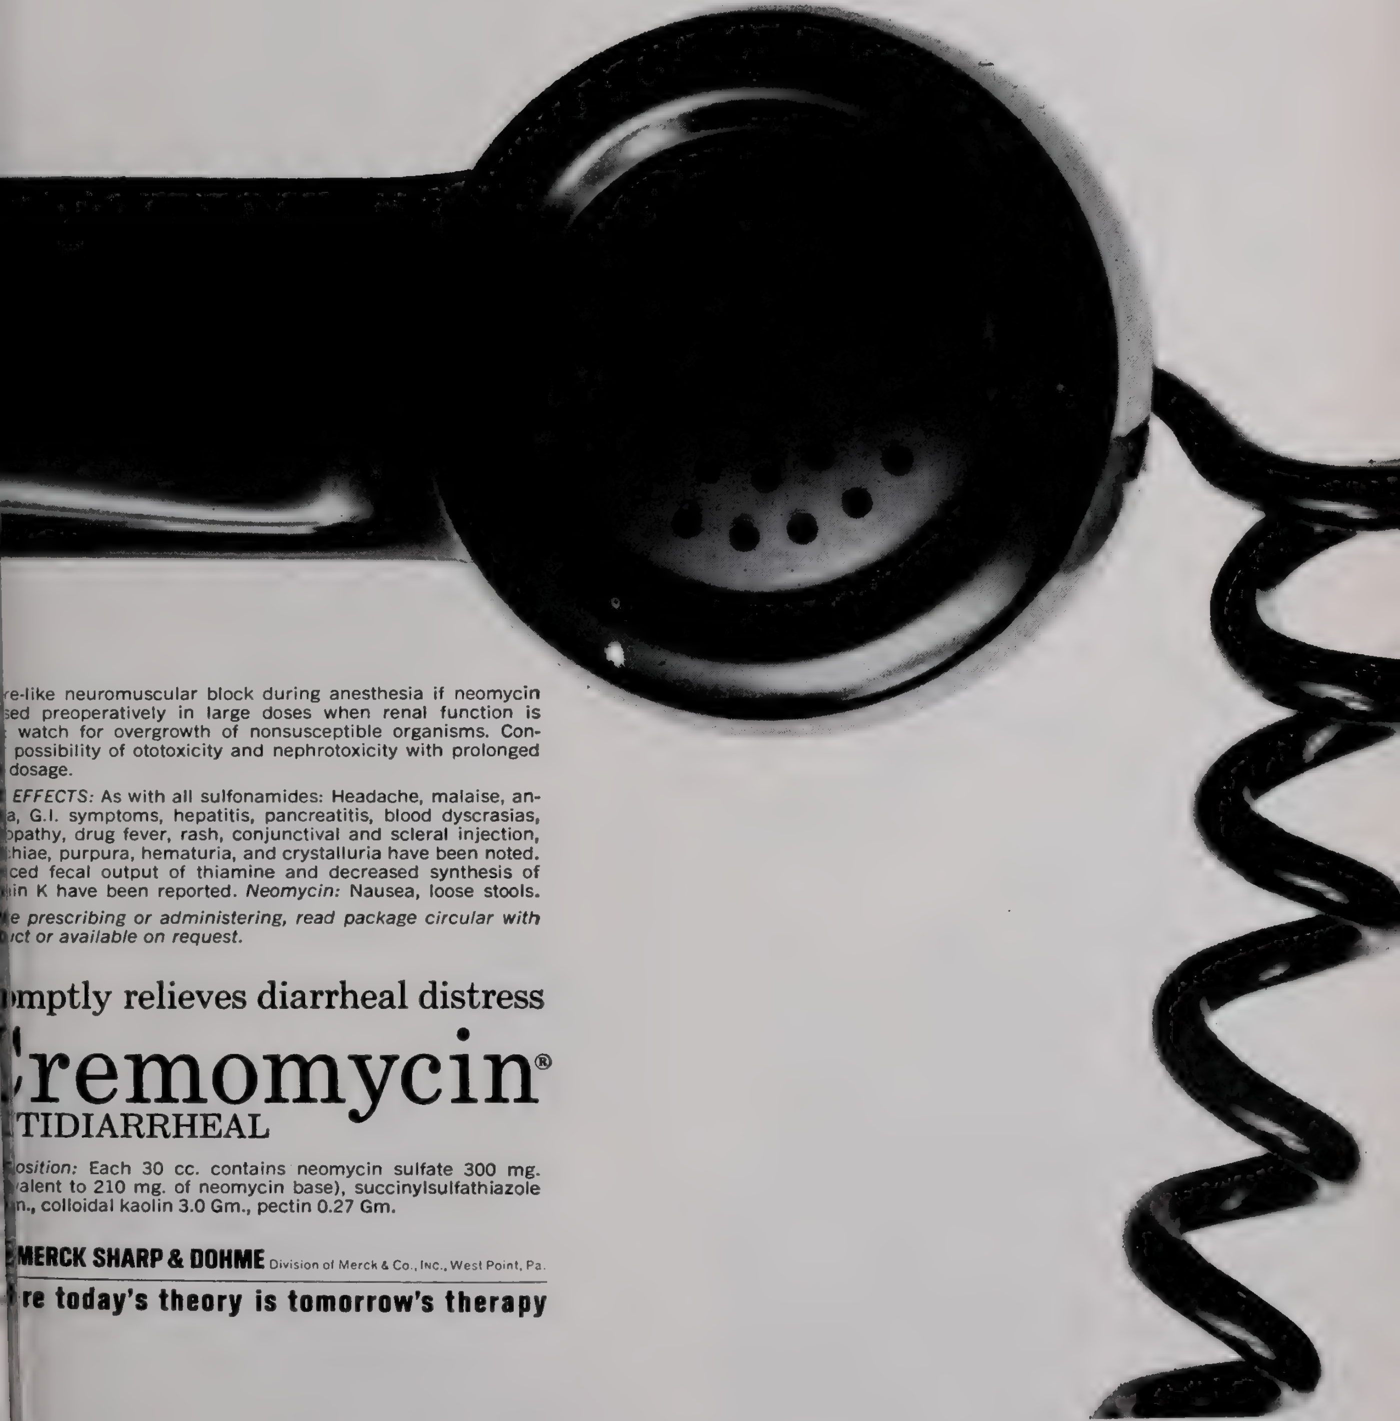
INDICATIONS: Diarrhea.

CONTRAINDICATIONS: Do not use in intestinal obstruction,
tensive ulceration of bowel, or diverticulosis; in hypersensiti
to sulfonamides or neomycin; in pregnancy at term, in prema
infants, or during first week of life in the newborn.

WARNINGS: Use only after critical appraisal in patients
hepatic or renal damage, urinary obstruction, or blood dys
sias. Fatal hypersensitivity reactions and blood dyscrasias
ported with use of sulfonamides. Consider periodic blood cou
hepatic and renal function tests during intermittent or chr
use.

PRECAUTIONS: Succinylsulfathiazole: Use with caution if t
is history of significant allergies and/or asthma. Continued
requires supplementary vitamins B_1 and K. *Neomycin:* Watc

your ℞ for
Cremomycin
can provide relief



re-like neuromuscular block during anesthesia if neomycin
sed preoperatively in large doses when renal function is
watch for overgrowth of nonsusceptible organisms. Con-
possibility of ototoxicity and nephrotoxicity with prolonged
dosage.

EFFECTS: As with all sulfonamides: Headache, malaise, an-
a, G.I. symptoms, hepatitis, pancreatitis, blood dyscrasias,
pathy, drug fever, rash, conjunctival and scleral injection,
hiae, purpura, hematuria, and crystalluria have been noted.
ced fecal output of thiamine and decreased synthesis of
in K have been reported. *Neomycin:* Nausea, loose stools.

*e prescribing or administering, read package circular with
ct or available on request.*

MERCK SHARP & DOHME Division of Merck & Co., Inc., West Point, Pa.

re today's theory is tomorrow's therapy

How long will it take her to recover from her hip fracture if she just doesn't care?

Does she really care? Is she alert, encouraged, positive and optimistic about getting completely well soon?

Or has she given in to the demoralizing impact of confinement, disability and dependency?

When functional fatigue complicates convalescence, Alertonic can help…

Pleasant-tasting Alertonic is pipradrol hydrochloride—an effective cerebral stimulant whose gentle analeptic action helps counteract the apathy and inertia that can often delay convalescence—together with an excellent vitamin and mineral formula, in a satisfying 15% alcohol vehicle.

Nothing fosters confidence and a sense of well-being better than your own personal warmth, understanding and encouragement together with Alertonic to help insure prompt response.

Adequate dosage is important: Prescribe Alertonic—one tablespoonful t.i.d., 30 minutes before meals…tastes best chilled.

And for your patient's sake, prescribe Alertonic in the convenient, economical one-pint bottle.

Alertonic®

Available Only On Prescription

Each 45 cc. (3 tablespoonfuls) contains: alcohol, 15%; pipradrol hydrochloride, 2 mg.; thiamine hydrochloride (vitamin B_1) (10 MDR[*]), 10 mg.; riboflavin (vitamin B_2) (4 MDR), 5 mg.; pyridoxine hydrochloride (vitamin B_6), 1 mg.; niacinamide (5 MDR), 50 mg.; choline,[†] 100 mg.; inositol,[†] 100 mg.; calcium glycerophosphate, 100 mg. (supplies 2% MDR for calcium and for phosphorus) and 1 mg. each of the following: cobalt (as chloride), manganese (as sulfate), magnesium (as acetate), zinc (as acetate), and molybdenum (as ammonium molybdate).

[*] Multiple of adult Minimum Daily Requirement supplied.

[†] The need for these substances in human nutrition has not been established.

Indications: 1. Functional fatigue such as that often associated with: a depressing life experience or stressful time of life; advancing years; convalescence; limited activity or confinement. 2. Poor appetite and vitamin-mineral deficiency as they occur in: patients having faulty eating habits; geriatric patients who are losing interest in food; patients convalescing from debilitating illness or surgery.

Dosage: Adults, 1 tablespoonful; children (over 15 years old), 1 to 2 teaspoonfuls; children (4 to 15 years old), 1 teaspoonful. To be taken three times daily 30 minutes before meals.

Contraindications: As with other drugs with CNS stimulating action, Alertonic is contraindicated in hyperactive, agitated or severely anxious patients and in chorea or obsessive compulsive states.

Side effects: Reports of overstimulation have been rare. Patients who are known to be unduly sensitive to the effects of stimulant drugs should be observed carefully in the initial stages of treatment.

Merrell

THE WM. S. MERRELL COMPANY

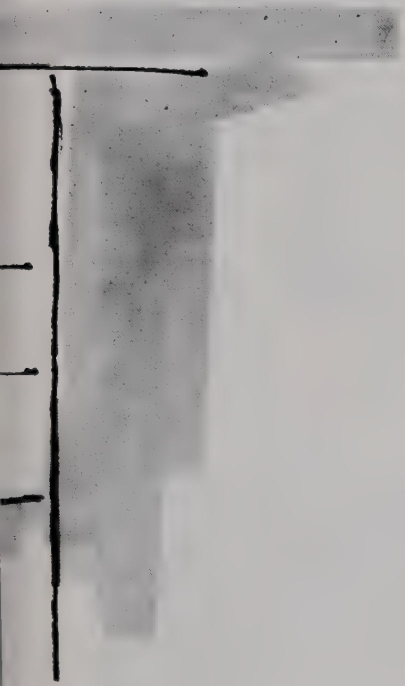
Cincinnati, Ohio 45215



Wait, Annabelle. Mommy hasn't told the doctor yet that you *need* a shot.

e she does, maybe she n't. But if her problem is l congestion due to cold lergy, consider the medi- n that combines conve- ce and effectiveness— histine Melet.

let is especially suitable treatment of children. It's easant tasting, chewable that leaves no aftertaste tty, undissolved particles in the mouth. It provides decongestant action almost as quickly as a liquid, but assures the accurate dosage of a tablet.

Because Melets are so convenient to carry and so easy to take at any time, adults, too, will appreciate this modern dosage form.

Use cautiously in individuals with severe hypertension, diabetes mellitus, hyperthyroidism or urinary retention. Caution adults who operate machinery or motor vehicles that drowsiness may occur. Each Melet contains phenylephrine hydrochloride 10 mg. and chlorpheniramine maleate 2 mg.

Merck Sharp & Dohme
understanding...
precedes development

The synthesis of cortisone was accomplished by Merck Sharp & Dohme in 1948—the famous "Compound E" used by Dr. Philip Hench in his historic experiment at the Mayo Clinic.

But proud as we are of our role in the development of cortisone and subsequent corticosteroids, we have continued to seek a greater understanding of arthritic disorders and new drugs for their treatment.

One such drug—INDOCIN* (indomethacin), a nonsteroid, anti-inflammatory agent fundamentally different in structure and activity from other drugs in use—was recently made available for the treatment of arthritic conditions. It opens new possibilities for the long-term management of arthritis and inflammatory disease.

MERCK SHARP & DOHME | **where today's theory is tomorrow's therapy**
Division of Merck & Co., INC., West Point, Pa.

INDOCIN®

INDOMETHACIN

Indications: Chronic and acute rheumatoid arthritis, rheumatoid (ankylosing) spondylitis, degenerative joint disease (osteoarthritis) of the hip, and gout.
Contraindications: Active peptic ulcer, gastritis, regional enteritis, or ulcerative colitis. Safety in pregnancy has not been established. Not recommended for pediatric age groups.
Warning: Patients who experience dizziness, lightheadedness, or feelings of detachment on INDOCIN should be cautioned against operating motor vehicles, machinery, climbing ladders, etc. Use cautiously in patients with psychiatric disturbances, epilepsy, or parkinsonism.
Precautions and Adverse Reactions: Most commonly, headache, dizziness, lightheadedness, G.I. disturbances. The C.N.S. effects are often transient and frequently disappear with continued treatment or reduced dosage. The severity of these effects may occasionally require cessation of therapy. G.I. effects may be minimized by giving the drug with food or with antacids or immediately after meals. Ulceration of the stomach, duodenum, or small intestine has been reported and, in a few instances, severe bleeding with perforation and death. Gastrointestinal bleeding with no obvious ulcer formation has also been noted; INDOCIN should be discontinued if G.I. bleeding occurs. As a result of G.I. bleeding, some patients may manifest anemia, and for this reason periodic hemoglobin determinations are recommended. Rare reports of effects not definitely known to be attributable to INDOCIN include bleeding from the sigmoid colon (either from a diverticulum or without a known previous pathologic condition), perforation of preexisting sigmoid lesions (diverticulum, carcinoma), and hematuria. In other rare cases, a diagnosis of gastritis has been made while the drug was being given. One patient developed ulcerative colitis, and another, regional ileitis, while receiving INDOCIN; when the drug was given to patients with preexisting ulcerative colitis, there was an increase in abdominal pain. Infrequently observed side effects may include drowsiness, tinnitus, mental confusion, depression and other psychic disturbances, blurred vision, stomatitis, pruritus, edema, and hypersensitivity reactions. Slight BUN elevation, usually transient, has been seen in some patients, although the preponderance of evidence indicates that INDOCIN does not adversely affect renal function, even in patients with preexisting renal disease. Nevertheless, renal function should be checked periodically in patients on long-term therapy. Leukopenia has been seen in a few patients. Transient elevations in alkaline phosphatase, cephalin-cholesterol flocculation, and thymol turbidity tests have been observed in some patients and, rarely, elevations of SGOT values; the relationship of these changes to the drug, if any, has not been established. As with any new drug, patients should be followed carefully to detect unusual manifestations of drug sensitivity. Before prescribing or administering, read product circular with package or available on request.

Sustained circulatory, respirato and cerebral stimulation for t

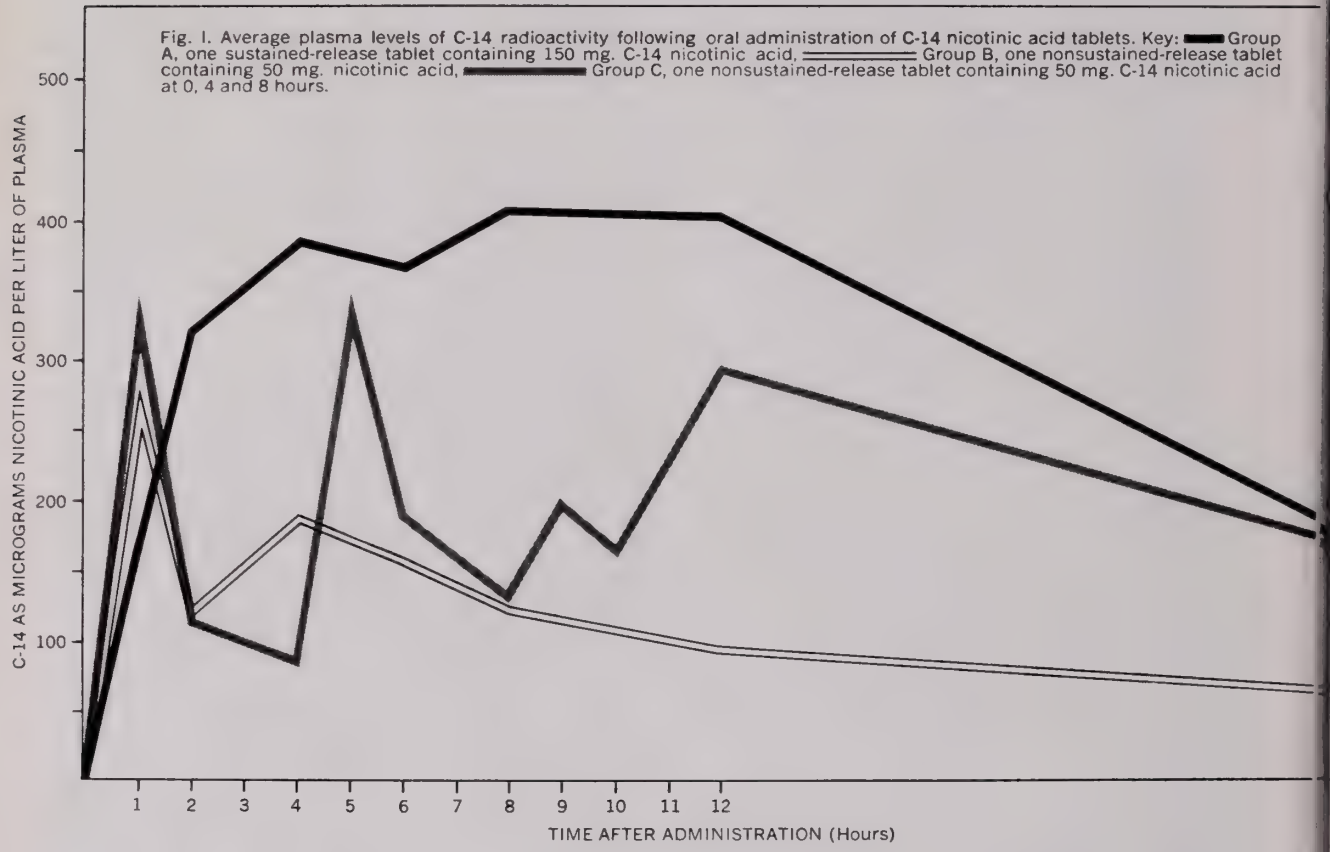

Fig. I. Average plasma levels of C-14 radioactivity following oral administration of C-14 nicotinic acid tablets. Key: ▬ Group A, one sustained-release tablet containing 150 mg. C-14 nicotinic acid, ═ Group B, one nonsustained-release tablet containing 50 mg. nicotinic acid, ▬ Group C, one nonsustained-release tablet containing 50 mg. C-14 nicotinic acid at 0, 4 and 8 hours.

(fewer absent doses by absent-minded patients

Human volunteer subjects were administered Geroniazol TT tablets with the nicotinic acid component made radioactive with C-14. Plasma and urine samples were analyzed. (See Figures I and II) The radioactive tracer study substantiated the previous clinical evidence that the release of nicotinic acid from the Geroniazol TT tablet produced a gradual rise in plasma levels to a plateau for a total of 12 hours and more.

Such proven sustained activity makes the management of geriatric patients much easier by minimizing the possibility of neglected doses through absent-

mindedness or senile confusion. Therapy *can* be
tinuous on a daily dose of only one Geroniazol TT
let every 12 hours.

The gradual release of nicotinic acid in Geron
TT will provide the well-known peripheral vasodi
tion needed in patients with deficient circulatior
with a minimum amount (if any) of "flushing."
cerebrovascular circulation is complemented by
tylenetetrazol, long-established as a cerebral anc
piratory stimulant.

Geroniazol TT improves the typical, unfortu
signs of senile confusion. Patients become more

ged and debilitated

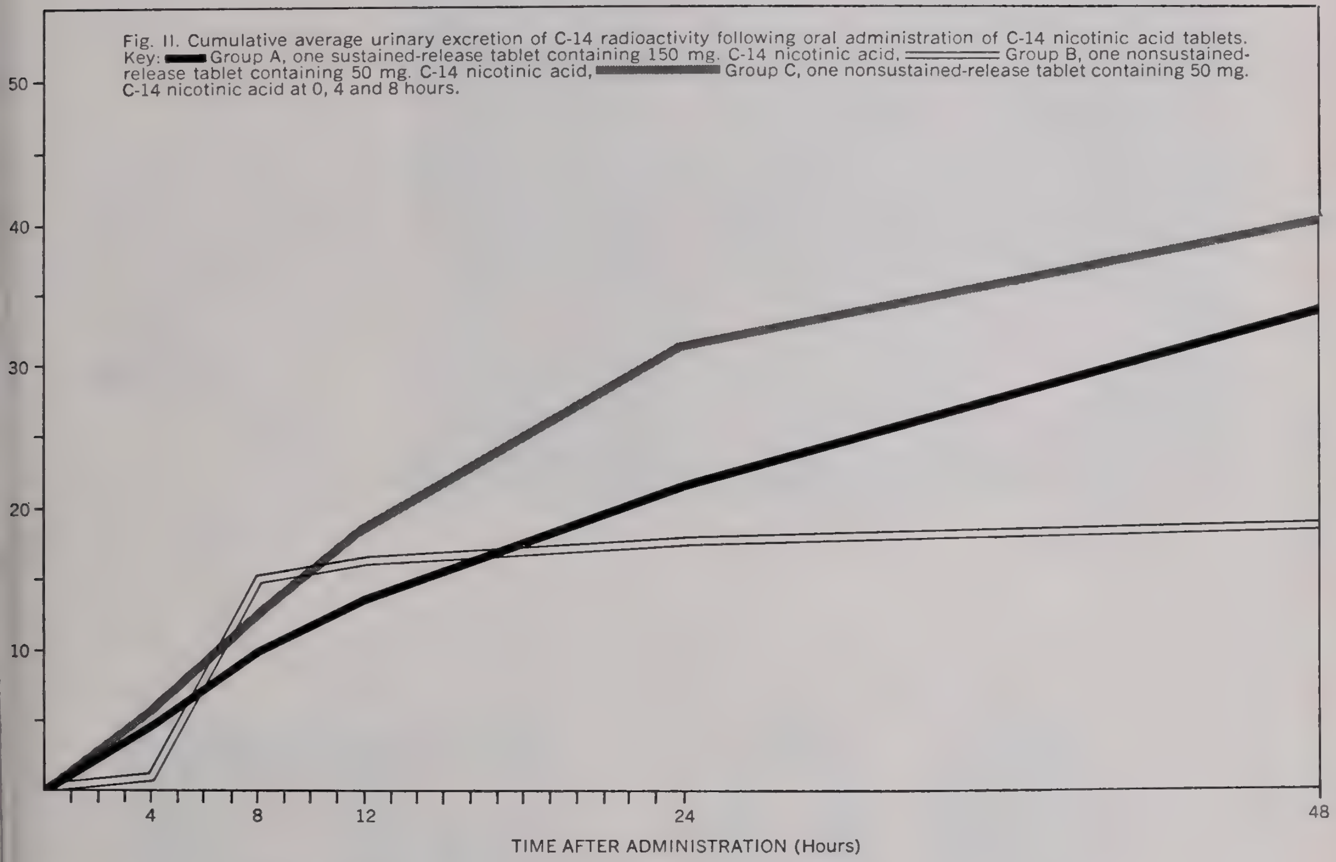

Fig. II. Cumulative average urinary excretion of C-14 radioactivity following oral administration of C-14 nicotinic acid tablets. Key: ▬ Group A, one sustained-release tablet containing 150 mg. C-14 nicotinic acid, ═ Group B, one nonsustained-release tablet containing 50 mg. C-14 nicotinic acid, ▬ Group C, one nonsustained-release tablet containing 50 mg. C-14 nicotinic acid at 0, 4 and 8 hours.

s confused and moody. Personal care, memory, otional stability, social attention improve. Fatigue, athy and irritability are reduced.

A prescription for 100 tablets of Geroniazol TT will rmit your patients to enjoy the benefits of time-olonged nicotinic acid/pentylenetetrazol therapy, an economical price. Dosage is only one tablet every hours.

ntraindications: There are no known contraindica-ns.

ecautions: Exercise caution when treating patients h a low convulsive threshold.

Side Effects: Side effects are rarely encountered, however due to the vasodilatation effect of nicotinic acid, transitory mild nausea, flushing, tingling and pruritus are possible.

Dosage: One tablet every 12 hours.

Supplied: Prescribe bottles of 100 tablets, to take advantage of recent price reduction.

Minnesota Medicine at a Glance

Surface Area and Dosage — Snively Page 1521

During the past century an increasing body of evidence has indicated that body surface area is directly related to such fundamental physiologic matters as heat production, cardiac output, glomerular filtration rate, blood pressure, organ size, oxygen consumption, nitrogen requirement, and plasma volume. It therefore appears to be our best gauge for dosage — far superior to age and to height, especially in the case of infants and children.

Until recently, determination of body surface area was a cumbersome matter. Now it can be done by the use of a simple chart from which one can read off body surface if he knows the weight. It can be similarly determined by the measurement of sitting height.

Authoritatively endorsed by the publication of the A.M.A. — *New Drugs;* by leading pediatric textbooks; by the National Formulary, and by an increasing number of teachers, it appears that body surface area will soon displace age and weight as a gauge for pediatric dosage. The rationale for body surface area and the simplicity of its application are explained in the article.

Surgical Treatment of Dizziness — Pulec Page 1529

The operation for continuous drainage of the endolymph fluid by a subarachnoid shunt, as described by Dr. Pulec, offers great promise for effective treatment of Meniere's disease in the relief of vertigo and preservation of hearing.

Left Ventricular Outflow — Karnegis and Wang Page 1545

Obstruction to the flow of blood from the left ventricle can occur at the aortic valve, above it, or below it. These all produce a pressure gradient which can be recorded by catheterization. As there are subtle differences among these conditions, definitive diagnosis can best be established by a cardiac catheterization or angiography.

Low Serum Cholesterol — Hunter Page 1555

Through the statistical evaluation and a determination of the factor of relative significance, Hunter has pointed out the importance of being cognizant of a low serum cholesterol level, as observed in a study of 750 patients. Though the incidence of low serum cholesterol is not high in any disease, it would seem to lend additional diagnostic value in those diseases in which Hunter has found it to be a factor of relative significance.

A review of this manuscript for both the positive and negative value is worth while.

Neurological Changes in Systemic Malignancy — Dyck Page 1629

Dr. Dyck reviews the expanding literature regarding a variety of neurological syndromes thought to be associated with systemic malignancies. These syndromes do not seem to be caused by actual invasion of the central or peripheral nervous system by metastatic lesions. Three syndromes are described in which a reasonably strong case can be made for a greater than chance relationship between malignancy and the neurologic syndrome. These include sensory neuropathy, myasthenic syndrome, and progressive multi-focal leukoencephalopathy. Other syndromes are discussed and some discrepancies between Mayo Clinic experience and other reported statistics are noted. A timely review of a little-known but important neurological problem.

Benadryl®
(diphenhydramine hydrochloride)
PARKE-DAVIS
for control of allergic symptoms

Whether the allergen is red and round, or unseen and unknown, BENADRYL provides relief of symptomatic distress through its antihistaminic and antispasmodic actions. *PRECAUTIONS:* Persons who have become drowsy on this or other antihistamine-containing drugs, or whose tolerance is not known, should not drive vehicles or engage in other activities requiring keen response while using this product. Hypnotics, sedatives, or tranquilizers if used with BENADRYL should be prescribed with caution because of possible additive effect. Diphenhydramine has an atropine-like action which should be considered when prescribing BENADRYL. *SIDE EFFECTS:* Side reactions, commonly associated with antihistaminic therapy and generally mild, may affect the nervous, gastrointestinal, and cardiovascular systems. Most frequent reactions are drowsiness, dizziness, dryness of the mouth, nausea, and nervousness. BENADRYL is available in Kapseals® of 50 mg. and Capsules of 25 mg. 00666

urethritis?
prostatitis?

in any case,
usually gram-negative*

Therapy:

two 500 mg. Caplets® q.i.
(initial adult dose)

NegGram

Brand of

nalidixic aci

a specific anti-gram-negative

eradicates most urinary tract infections...

- Low incidence of untoward effects; no fungal overgrowth, crystalluria, ototoxic or nephrotoxic effects have been observed.

- "Excellent" or "good" response reported *in more than 2 out of 3* patients with either chronic or acute gram-negative infections.[1]

*As many as 9 out of 10 urinary tract infections are now caused by gram-negative organisms: E. coli, Klebsiella, Aerobacter, Proteus, Paracolon or Pseudomonas[2]... However, infections of the urethra and prostate caused by non-gonococcal gram-negative organisms are believed to be less prevalent.

Indications: Urinary tract infections caused by gram-negative and some gram-positive organisms.

Side effects: Mainly mild, transient gastrointestinal disturbances; in occasional instances, drowsiness, fatigue, pruritus, rash, urticaria, mild eosinophilia, reversible subjective visual disturbances (overbrightness of lights, change in visual color perception, difficulty in focusing, decrease in visual acuity and double vision), and reversible photosensitivity reactions. Marked overdosage, coupled with certain predisposing factors, has produced brief convulsions in a few patients.

Precautions: As with all new drugs, blood and liver function tests are advisable during prolonged treatment. **Pending further experience, like most chemotherapeutic agents, this drug should not be given in the first trimester of pregnancy. It must be used cautiously in patients with liver disease or severe impairment of kidney function.** Because photosensitivity reactions have occurred in a small number of cases, patients should be cautioned to avoid unnecessary exposure to direct sunlight while receiving NegGram, and if a reaction occurs, therapy should be discontinued. The dosage recommended for adults and children should not arbitrarily be doubled unless under the careful supervision of a physician. Bacterial resistance may develop.

When testing the urine for glucose in patients receiving NegGram, Clinistix® Reagent Strips or Tes-Tape® should be used since other reagents give a false-positive reaction.

Dosage: Adults: Four Gm. daily by mouth (2 Caplets® of 500 mg. four times daily) for one to two weeks. Thereafter, if prolonged treatment is indicated, the dosage may be reduced to two Gm. daily. Children may be given approximately *25 mg. per pound* of body weight per day, administered in divided doses. The dosage recommended above for adults and children should not arbitrarily be doubled unless under the careful supervision of a physician. Until further experience is gained, infants under 1 month should not be treated with the drug.

How supplied: Buff-colored, scored Caplets® of **500 mg. for adults,** conveniently available in bottles of 56 (sufficient for one full week of therapy) and in bottles of 1000. **250 mg. for children,** available in bottles of 56 and 1000.

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

STOP anxiety

but not

your

patient

For your anxious patients who must remain active, 'Stelazine' offers a specific, incisive antianxiety effect that can calm excessive anxiety without producing annoying dulling effects. On 'Stelazine' patients react more normally to stresses and at the same time remain alert enough to carry on their normal activities.

Stelazine®

brand of **trifluoperazine**

Before prescribing, the physician should be familiar with the complete prescribing information in SK&F literature or *PDR*. The following is a brief precautionary statement. *Contraindications:* Comatose or greatly depressed states due to C.N.S. depressants and in cases of existing blood dyscrasias, bone marrow depression and liver damage. *Precautions:* Use with caution in angina patients and in patients with impaired cardiovascular systems. Antiemetic effect may mask symptoms of other disorders. An additive depressant effect is possible when used with other C.N.S. depressants. Prolonged administration of high doses may result in accumulative effects with severe C.N.S. or vasomotor symptoms. Use in pregnant patients only when necessary for the patient's welfare. *Side Effects:* Occasional cases of mild drowsiness, dizziness, mild skin reactions, dry mouth, insomnia and amenorrhea. Neuromuscular (extrapyramidal) reactions (motor restlessness, dystonias, pseudo-parkinsonism) may occur and, in rare instances, may persist. In addition, muscular weakness, anorexia, rash, lactation, hypotension, and blurred vision have been observed. Blood dyscrasias and cholestatic jaundice have been extremely rare. For a comprehensive presentation of 'Stelazine' prescribing information and side effects reported with phenothiazine derivatives, please refer to SK&F literature or *PDR*.

President's Letter

THREE INQUIRIES — national, regional and local — into the training, the post-graduate education, and the distribution of physicians have involved the University of Minnesota Medical School, the Legislature of the State of Minnesota, and all physicians in a growing problem.

With publication of the study of the Health Manpower, the regional and state aspects of physician education supply and distribution are being clarified. The Hill Study is complete, and its conclusions and recommendations are published. The Legislative Sub-committee is still deliberating after meetings with representative physicians and other responsible medical organizations.

The third inquiry, commissioned by the American Medical Association became public in early October of this year.

The obvious conclusion drawn from these three inquiries is recognition of the national extent of the problem being considered in Minnesota at present on a state and regional basis.

The graduation of more physicians in Minnesota, the possibility of expanding our present medical school, the acceptance of more applicants from adjoining two-year schools, the development of a new medical school in Minnesota, an increase in number and change of format in medical school courses for generalists are the local proposals for meeting the national need for more physicians.

The provision for medical care to an expanding population, grown more sophisticated in demanding such care as a result of Federal programs, the expansion of prepaid group and individual plans, and rising personal incomes are responsibilities which medicine itself must recognize and assume.

Parallel situations exist in every phase of American life, education, paramedical technology, dentistry and the rest. Parallel efforts are being made to decrease shortages and improve distribution.

That the American Medical Association concerned with the twin-problem of medical education and physician availibility chose to go outside medicine by the appointment of the Citizens Committee indicates recognition of the value of non-involved opinion.

The same technique used in a somewhat different field of approach, in the Hill report, gave a depth to conclusions and recommendations which would have been more difficult to arrive at by a physician-dominated committee.

Ultimately, the effect of physician shortages in all areas of practice will be advanced by industry, by communities, by insurance carriers, and by those involved in the development of the resources of our State.

The solution will involve every citizen of Minnesota, and Medicine will do well to consider this in offering opinions and suggesting changes sound in concept and capable of execution.

two to four times
the therapeutic
activity of other
erythromycins

CONTRAINDICATIONS: Ilosone is contraindicated in patients with a known history of sensitivity to this drug and in those with preexisting liver disease or dysfunction.

SIDE-EFFECTS: Even though Ilosone is the most active oral form of erythromycin, the incidence of side-effects is low. Infrequent cases of drug idiosyncrasy, manifested by a form of intrahepatic cholestatic jaundice, have been reported. There have been no known fatal or definite residual effects. Gastro-intestinal disturbances not associated with hepatic effects are observed in a small proportion of patients as a result of a local stimulating action of Ilosone on the alimentary tract. Although allergic manifestations are uncommon with the use of erythromycin, there have been occasional reports of urticaria, skin eruptions, and, on rare occasions, anaphylaxis.

DOSAGE: *Children under 25 pounds*—5 mg. per pound of body weight every six hours. *Children 25 to 50 pounds*—125 mg. every six hours. *Adults and children over 50 pounds*—250 mg. every six hours. For severe infections, these dosages may be doubled.

Available in Pulvules®, suspension, drops, and chewable tablets. Ilosone Chewable tablets should be chewed or crushed and swallowed with water.

Additional information available to physicians upon request.

Extracranial Internal Carotid Artery*

Surgery
for the
Occluded
Totally

JOSEPH J. GARAMELLA, M.D.
MICHAEL F. LYNCH, M.D.
NATHAN KENNETH JENSEN, M.D.
LAURENCE P. STERNS, M.D.
W. ROBERT SCHMIDT, M.D.
Minneapolis, Minnesota

SINCE EASTCOTT, PICKERING and Rob[6] performed successful arterial resection and primary anastomosis for extracranial carotid artery stenosis in 1954, many reports support the surgical method of treating strokes in carefully studied and selected cases. The magnitude of the problem of cerebrovascular insufficiency, ranked as the third killer in the United States and responsible for 197,590 deaths in 1962, warrants a careful analysis of the results of treatment.

Under special consideration in this manuscript is a group of patients with total occlusion of the extracranial internal carotid artery. Are these patients candidates for surgery? Can the circulation be restored? Is there a sharp limitation in time from the onset of occlusion to the time of successful surgery? Discouraging reports can be found in the literature, most indicating that surgical efforts are unrewarding. Our personal experiences with this problem differ, indicating that in a substantial number of these patients, restoration of circulation can be accomplished as long as three weeks following the onset of total arterial occlusion.

Material

From the period March 2, 1958, to July 10, 1965, extracranial arterial disease producing cerebrovascular insufficiency was encountered in 140 patients. Twenty-four persons had bilateral carotid disease requiring operation. Of the 140 patients, 102 had internal carotid stenosis and 28 had total internal carotid occlusion. Total internal carotid artery occlusion thus occurred in 20% of the entire group. These and other lesions encountered are shown in Table 1. Our previous report[19] analysed the first 50 of these cases. The results of this continuing experience have been comparably encouraging, 82% of patients being improved or symptom-free after surgery.

---

*Presented at the meeting of the Minnesota Surgical Society, Minneapolis, Minnesota, May 17, 1965.

See editorial page 1719.

Total Occlusion of Internal Carotid Artery

Twenty-eight of 140 patients had total occlusion of the extracranial internal carotid artery demonstrated by arteriography, percutaneous direct carotid injection, or by retrograde methods. Twenty-seven were operated. Fifteen of the 24 patients had bilateral arteriograms or aortic arch studies. Ten of these had bilateral disease, eight of whom underwent bilateral surgery. One patient had bilateral total occlusion of the internal carotid arteries.

Age and Sex

Ages ranged from 43 to 73 years. Seven of the 28 patients were less than 50 years. Twenty-four were males and four were females.

Symptoms

Sensory, motor, and visual disturbances were transient in 20 and persistent in eight of the 28 patients. Headaches, lightheadedness, dizziness, and fainting were also among the symptoms of some patients.

Interval from Onset of Total Occlusion to Time of Surgery

The time of total occlusion of the internal carotid artery was identified with the last preceding transient or persistent stroke prior to arteriography. Among 12 cases in which circulation was restored, intervals varied from eight hours to 21 days. In one instance (Case 23), transient symptoms commenced three months prior to arteriography and were not sufficiently separated to permit an accurate determination of the time of total occlusion (Table 2).

Among 15 patients in whom circulation was not restored by surgery, the onset of total occlusion was indeterminate in six. In the remaining nine, intervals varied from seven to 28 days (Table 3).

Operative Technique

All patients were operated under general anesthesia, and the methods for endarterectomy with and without patch grafting previously described were employed.[19] Intraluminal shunts were used occasionally to aid in arterial repair. In three cases heparin was administered in the preoperative period pending surgery. Heparin (50-75 mgm.) was employed prior to carotid artery clamping and was neutralized with protamine following endarterectomy and arterial repair.

Four times Fogarty balloon catheters[9] have been used in extracting soft clots, and in three instances retrograde flow was estab-

lished after all other maneuvers such as forceps extraction and catheter suctioning had failed (Figure 3).

Pathology

In 25 cases there was chronic arteriosclerotic, partial occlusion with a superimposed recent thrombus (Figure 1) producing the total occlusion. In two cases, there was recent thrombosis of the internal carotid artery without significant arteriosclerosis at the carotid bifurcation. In these cases, it was felt that the occlusive process initiated intracranially and propagated extracranially.

Anatomical and Operative Results

Retrograde flow was established and the circulation was successfully restored in 12 of 27 patients operated or 12 of 28 arteries explored, one patient having total occlusion of both internal carotid arteries. Operative arteriograms were done in seven instances demonstrating arterial reconstruction and restoration of the intracranial circulation (Figures 2, 3, 4). In four instances arteriograms at seven days, eight days, six months, and 12 months postoperatively showed continued patency of the operated vessels.

There was one operative death in a 47-year-old man operated in a comatose state 36 hours after the onset of stroke. Despite a simple and expeditious endarterectomy, he died 40 hours later, never regaining consciousness. Autopsy was not performed.

Functional Results

Follow-up studies in eleven of twelve surviving patients in whom circulation was restored, classified according to Gurdjian,[11] show that seven are working and four are walking, one to 25 months following surgery. Among 13 patients followed in whom circu-

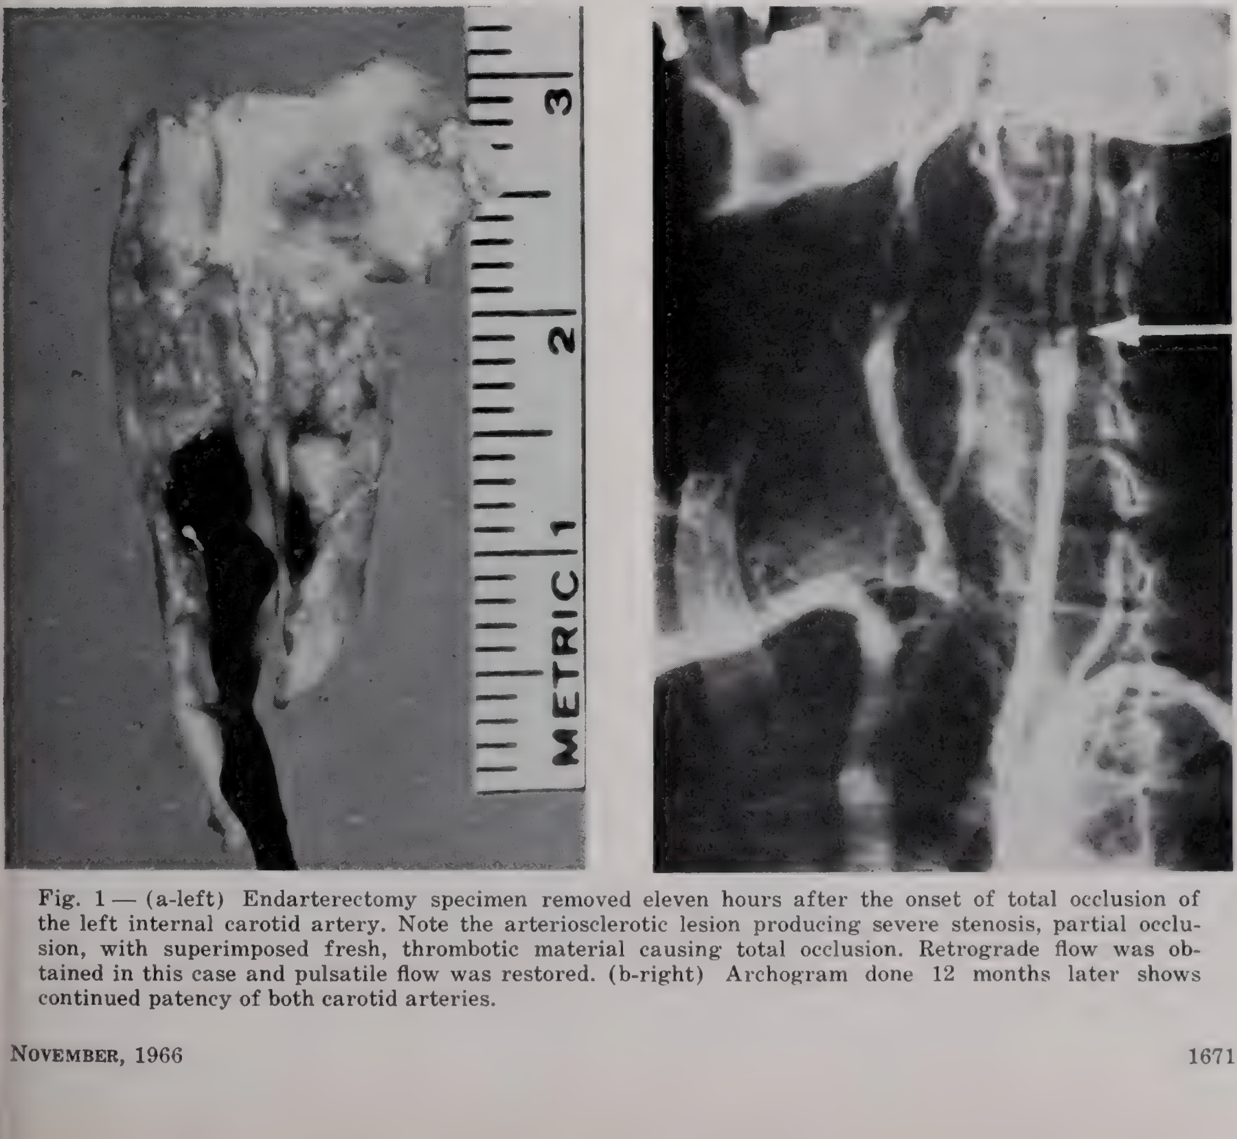

Fig. 1 — (a-left) Endarterectomy specimen removed eleven hours after the onset of total occlusion of the left internal carotid artery. Note the arteriosclerotic lesion producing severe stenosis, partial occlusion, with superimposed fresh, thrombotic material causing total occlusion. Retrograde flow was obtained in this case and pulsatile flow was restored. (b-right) Archogram done 12 months later shows continued patency of both carotid arteries.

lation was not restored, one died, four are working, four are walking, and four are wheel-chair patients.

The vagaries in following the functional aspects of surgery are well demonstrated in one of our patients, a 48-year-old man with intermittent right-sided strokes of three weeks' duration. On the day of hospitalization he became aphasic and developed a right hemiplegia. An archogram showed total occlusion of both internal carotid arteries and stenosis of one vertebral artery. Surgical exploration of both carotid arteries the same day disclosed old, chronic occlusion of the right internal carotid artery which was cordlike. The left internal carotid artery showed an atherosclerotic stenosis with a superimposed thrombus extending centrally. Circulation was not restored in either vessel. His prognosis was considered hopeless. However, with diligent and continuous nursing care by his wife, he survived, regained function of his paralysed side and began to phonate again. Continued evaluation of these results is necessary.

Discussion

Increasing recognition of extracranial vascular occlusions as the basis of strokes has led to more frequent use of arteriographic techniques for clarification of diagnosis and method of management.

In well selected cases of significant extracranial arterial stenosis, surgical procedures relieving the stenosis appear to be well established and uniformly good results can be expected in the majority of patients so treated. Admittedly, the functional results are more difficult to evaluate than the anatomical corrections made, and long-term studies are necessary for further elucidation.

Conflicting and contradictory views are found in the literature relating to the management of the totally occluded extracranial internal carotid artery. Thompson and Austin,[21] although restoring flow in 14 or 34 completely occluded internal carotid arteries, duration of occlusion not established, recommended exploration in acute occlusions of short duration, preferably hours, and in those in whom the arteriogram showed a pa-

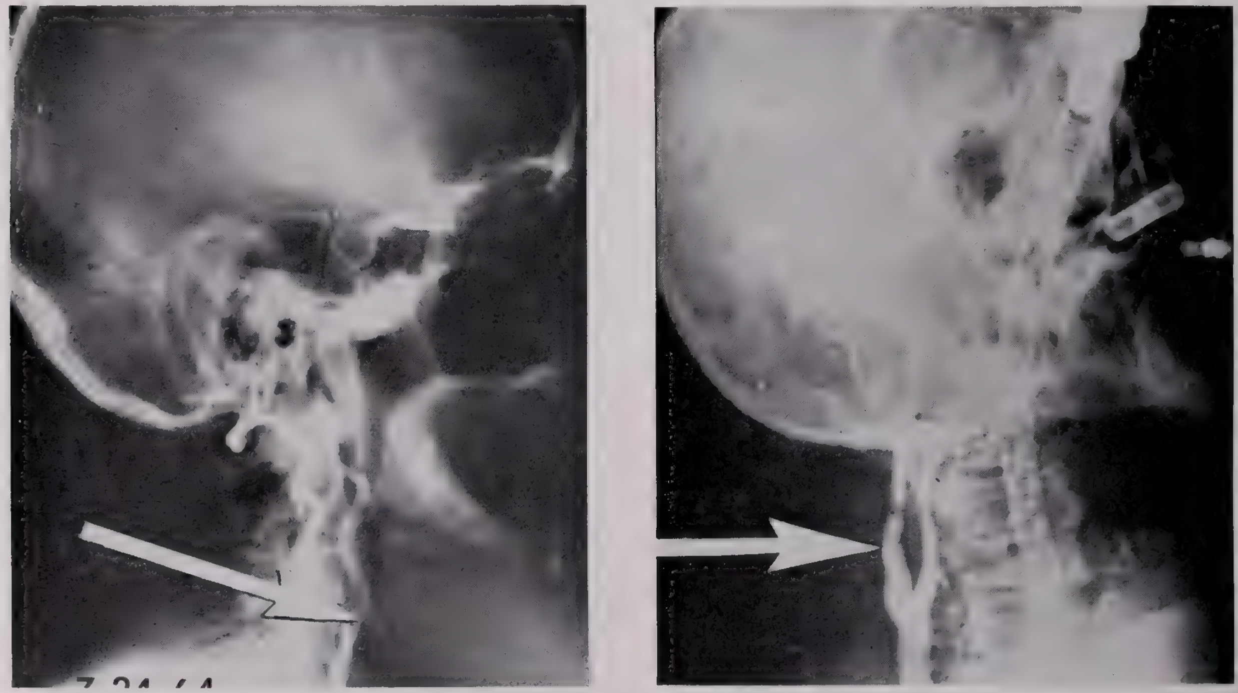

Fig. 2 — Case Nine: Duration of total occlusion on basis of history in this case was 18 days. (a-left) Preoperative arteriogram showing total occlusion of the internal carotid artery and absence of filling of the intracranial circulation. (b-right) Operative arteriogram following endarterectomy, thrombectomy, and arterial reconstruction. Flow has been re-established in the extracranial internal carotid artery, and the intracranial circulation is now evident. Revision of arteriotomy site shows improved caliber of internal carotid artery.

tent distal artery. Young and associates,[26] unable to restore flow in 14 patients with complete occlusions of greater duration than 24 hours, no longer operate these patients. Harrison[16] stated that the prospects of opening a totally occluded carotid artery after 24 to 48 hours are nil.

DeBakey[3] concurred with early intervention in the problem of total occlusion and previously reported[4] that complete occlusions were rarely operable unless explored soon after onset of symptoms. In a more recent report,[5] successful operation of a completely obstructed internal carotid artery was done in a patient with progressive neurologic manifestations of three months' duration.

Javid[18] stated that complete occlusion of the internal carotid artery is not an operable lesion, being unsuccessful in seven explorations. Cooley[2] advised exploration only in the acute occlusions because of the low success rate in restoring circulation in the chronically occluded cases. Ellis,[8] too, held little chance for restoring circulation unless the occlusion was of relatively recent origin. Whisnant[22] and associates again supported this stand. Wisiol[23] reported poor results with total arterial occlusions, as did Bahnson,[1] Murphey,[20] Edwards,[7] and Haller.[14]

Gunning[10] reported restoration of flow in five of 15 totally occluded arteries, three of which subsequently thrombosed. Hardin[15] reported ten cases of completely occluded internal carotid arteries, four of which died following surgery, apparently in progressive stroke. Hohf[17] reported six of 12 totally occluded arteries patent six months after operation. The duration of total occlusion was not given.

In Gurdjian's extensive experience with the overall problem of carotid artery occlu-

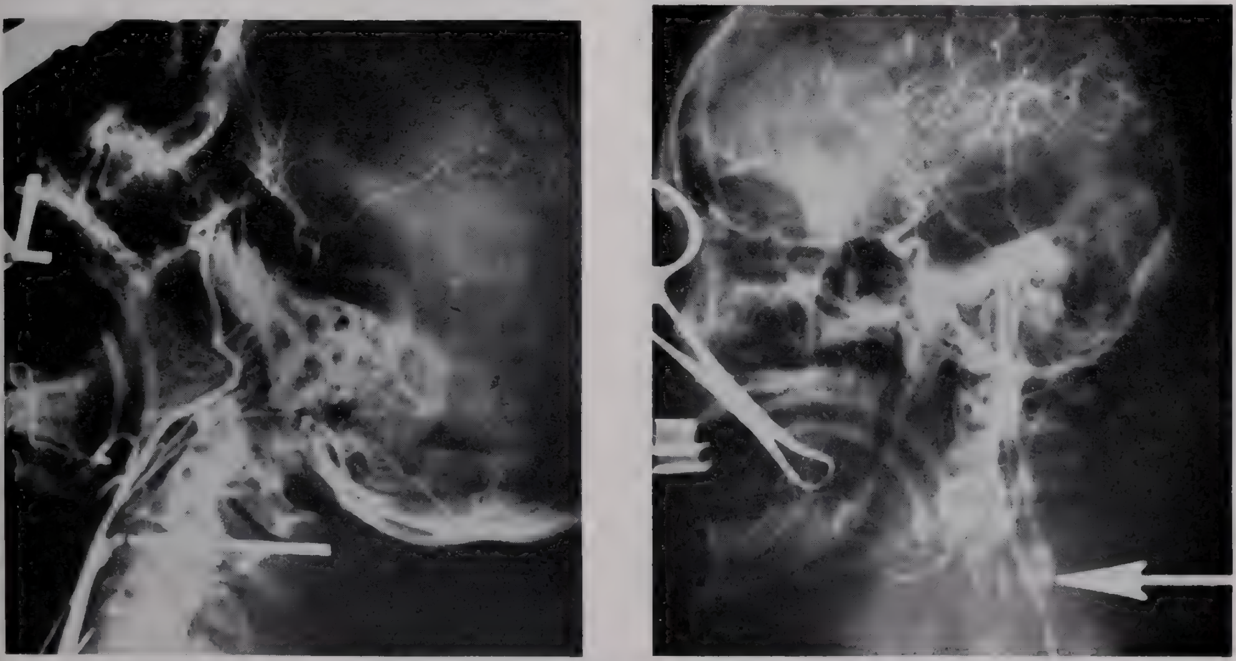

Fig. 3 — Duration of occlusion on the basis of history was nine days. (a-left) Preoperative arteriogram shows total occlusion of the carotid bifurcation. (b-right) Operative arteriogram following endarterectomy and thrombectomy shows restoration of flow and intracranial filling.

sion[12] restoration of flow in seven of 16 completely occluded internal carotid arteries, one three weeks after the onset of occlusion, led to the recommendation that endarterectomy be considered when on the basis of history the occlusion occurred within three to four weeks. His experience with the totally occluded internal carotid artery has been further extended, restoration of flow being accomplished in 13 of 24 cases operated, one case 22 days after the onset of total occlusion.[13]

Our experience parallels that of Gurdjian's, and it seems reasonable to explore the totally occluded carotid artery when by history the duration of occlusion is three to four weeks. In only one of the 12 successfully operated cases, Case 23, Table 2, was the duration of occlusion indeterminate. In six of 15 unsuccessful cases, Table 3, the duration of occlusion was indeterminate.

Restoration of flow in the totally occluded internal carotid artery did not cause worsening or death of the patient.

Wylie and Adams[24,25] reported six of 12 patients dying following restoration of flow in occluded arteries operated eight hours to two days after the onset of neurologic change and apparently stable at the time of surgery. They point to the hazard of perfusing ischemic brain tissue with blood at normal pressure. Four of their six deaths showed hemorrhagic infarcts at autopsy. Three of the 12 cases in which flow was restored in our series were operated in the acute phase of occlusion, eight, 11, and 36 hours after onset of symptoms. Two did well. One of these patients was operated in a state of coma 36 hours after his stroke and he never regained consciousness. Autopsy was not done.

Pertinent to this aspect of the problem, we have operated five patients with total occlusion of the common carotid artery. One patient was operated three days after the onset of a progressive stroke. Endarterectomy was unsuccessful and she died five days postoperatively. Autopsy showed massive, nonhemorrhagic, brain infarction. A second patient with chronic occlusion of the left common carotid artery had a subclavian to carotid artery anastomosis and died nine hours postoperatively. Autopsy showed massive, hemorrhagic infarction of the brain. A

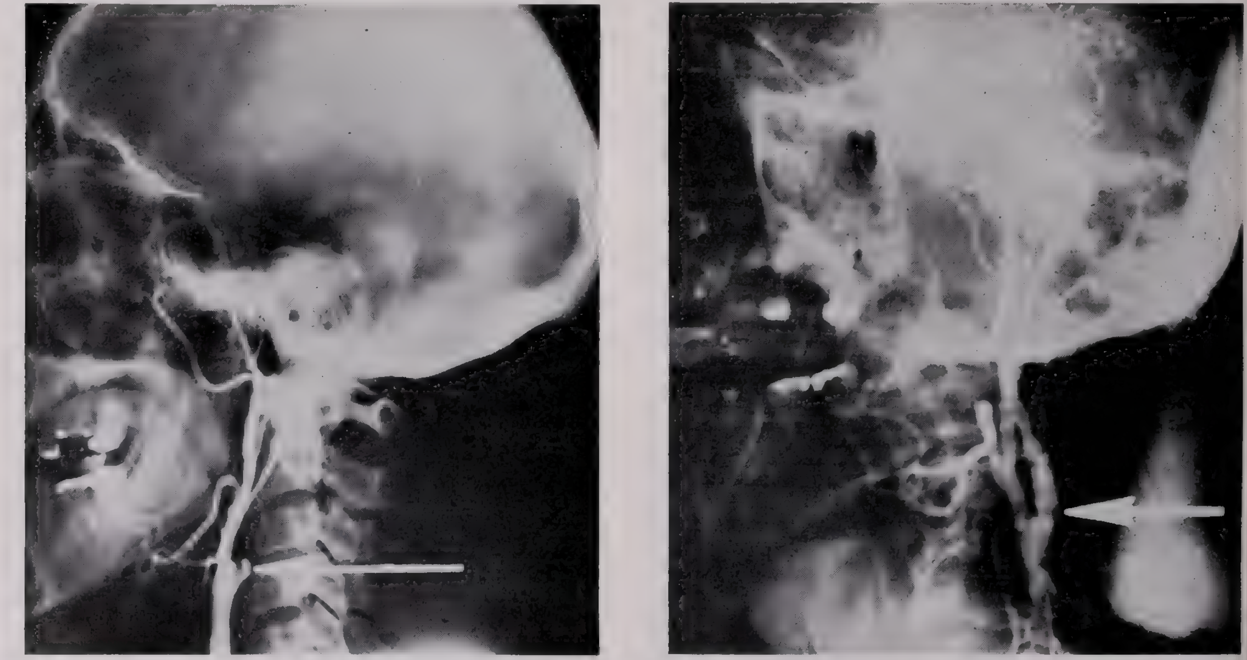

Fig. 4 — Duration of occluded internal carotid on the basis of history was 19 days. (a-left) Preoperative carotid arteriogram showing occlusion at the origin of the internal carotid artery and absence of intracranial circulation. (b-right) Following endarterectomy and thrombectomy, operative arteriogram shows restoration of flow and established intracranial circulation. An archogram seven days later for clarification of other extracranial vessels showed continued patency of the operated vessel.

third patient with progressive neurologic symptoms of one week's duration had total occlusion of the common carotid artery with a soft clot extending into the internal carotid artery. This was removed with a Fogarty balloon catheter and retrograde flow was established in the internal carotid artery. A graft was inserted on the ascending aorta and anastomosed to the common carotid artery proximal to the bifurcation, bypassing the chronic occlusion of the common carotid artery. Two days postoperatively he died. Autopsy showed marked subarachnoid hemorrhage and extensive encephalomalacia of the right cerebral hemisphere. Small areas of softening of the left occipital area and numerous petechial hemorrhages in the pons were also noted.

Two other patients with common carotid artery occlusion had subclavian to common carotid artery shunts, one with chronic occlusion of indeterminate duration and the other with occlusion of ten days' duration. This last patient also had significant stenosis of the opposite internal carotid artery, for which surgery was done. Both these patients did well. Although the factors producing hemorrhage in the brain following restoration of flow in occluded arteries are not entirely clear, the hazard must be recognized.

The consistent pathologic feature of these cases of totally occluded internal carotid artery has been chronic, atherosclerotic stenosis with a superimposed fresh thrombus that produces the total occlusion. With varying periods of time, the fresh thrombotic lesion propagates centrally. It seems reasonable, as with the management of other acute arterial occlusions, that anticoagulants be administered at the time that the diagnosis is established or suspected to prevent clot propagation.

Furthermore, our encouraging experiences with the use of Fogarty balloon catheters (three of four cases successful) in retrieving distal clot not otherwise removed by instrumentation and catheter suctioning, suggests that a more aggressive and persistent attack on these totally occluded arteries will lead to restoration of flow in a higher percentage of cases.

Summary and Conclusions

In a series of 140 patients with cerebrovascular insufficiency, in a six and one-half year period, 162 operations were carried out. Of special interest were 28 patients, 20% with total occlusion of the extracranial internal carotid artery.

Surgery was done on 27 of these patients, one of whom had bilateral occlusion of the internal carotid arteries. Thus, 28 totally occluded carotid arteries were explored. Restoration of flow by endarterectomy and thrombectomy was accomplished in 12 patients, 44.4%, or in 42.8% of the vessels operated.

The interval from the onset of total occlusion to the time that surgery was performed varied from 11 hours to 21 days. Contrary to most reports in the literature, restoration of flow in the totally occluded extracranial internal carotid artery is possible in a significant number of cases. The interval between the onset of total occlusion to the time of surgery need not be limited to a matter of hours and may, in fact, be weeks. On the basis of this experience, exploration of the totally occluded extracranial internal carotid artery is advised, if the duration of occlusion is within three to four weeks. Administration of heparin preoperatively, once the diagnosis is suspected or established, seems advisable, as in dealing with other acute arterial occlusions. The use of Fogarty balloon catheters as aids in performing thrombectomy merits further trial.

Addendum

Since presentation of this manuscript, four additonal patients have had successful restoration of the totally occluded extracranial internal carotid artery with the aid of Fogarty balloon catheters. Operative arteriograms have confirmed the restoration of flow.

The average man plays to the gallery of his own self-esteem. — Elbert Hubbard

Varnet's Syndrome*

(Jugular Foramen Syndrome)

This syndrome was first described by Varnet in 1918. It is evidenced by hoarseness, dysphagia of solids, and nasal regurgitation of fluids. The palate, pharynx, and larynx are involved, and the difficulty in swallowing is due to paralysis of the glossopharyngeal nerve which often causes a disturbance of taste over the posterior one third of the tongue.

The lesion occurs in the region of the jugular foramen where the ninth, tenth, and eleventh cranial nerves leave the skull at the hypoglossal foramen.

Paralysis of the vagus nerve results in dysphagia and hoarseness. Involvement of the spinal accessory nerve may cause paralysis and atrophy of the trapezius and the sternocleidomastoid muscle.

The lesion causing this syndrome may be a result of direct trauma, but can occur from an aortic aneurysm, carcinoma involving the esophagus, or from localized pressure from some other source.

Medical Men on Postage Stamps*

Albert Schweitzer (1875-1965), medical missionary to French West Africa, built at Lambarene, Gabon Province, a primitive hospital with his own and native labor, where, operating far into the night, he waged his relentless war against leprosy, sleeping sickness, and other tropical diseases. His heroic and noble work has been commemorated on postage stamps by Monaco in 1955, by Gabon in 1960, and by Germany in 1965.

Ephraim McDowell (1771-1830) was an American surgeon, who in 1809 performed the first operation recorded in the United States in ovarian surgery. In 1959 he was honored by the issuance of a U. S. postage stamp.

In Brief

There are three stages in the history of every medical discovery. When first announced, people say that it is not true. Then, a little later, when the truth has been borne in on them, so that it can no longer be denied, they say it is not important. After that, if its inportance becomes sufficiently obvious, they say anyhow it is not new. — R. McNair Wilson

Coumarin-Induced Bleeding Complications

Report of Eight Unusual Cases from One Hospital

RICHARD L. REECE, M.D.
PHILIP A. OLSON, M.D.
Minneapolis, Minnesota

> *"Drugs can be standardized,*
> *but patients cannot."*
>
> *Herrman Blumgart, M.D.*
> *Professor of Medicine, Emeritus*
> *Harvard Medical School*

THE PHYSICIAN who prescribes anticoagulants trades the threat of thrombosis for the risk of hemorrhage. While the odds favor the physician, the patient suffers the consequences. In the last eighteen months at St. Barnabas Hospital, a 315-bed institution, eight patients have presented with unusual coumarin-induced complications. Because awareness of similar complications may lead to proper treatment in future patients, we believe their histories are worth telling.

Case Report

*Epidural Hematoma**

A 51-year-old engineer was admitted on September 12, 1964, with a four-day history of chest pain radiating to the back and shoulders. He had had two previous myocardial infarctions and had been receiving bisoxycoumarin (Dicumarol) since 1962. Physical examination was normal. His laboratory work included a hemoglobin of 14.7 gm.%, a white blood cell count of 12,000 with 80 neutrophils, 40-50 red cells/h.p.f. in the urine, and a prothrombin time of 39 seconds (control 12.2 seconds).

On the second hospital day he developed tender neck muscles with ecchymoses of the skin. The prothrombin time was then 36 seconds. On the fourth day he became quadriplegic. A lumbar puncture showed 15,000 rbc. and a protein of 4.7/100 ml. A myelogram demonstrated a complete block (Figure 1). A cervical laminectomy was performed, but he died shortly after the operation.

At autopsy, a large organized epidural hemorrhage compressed the anterior spinal cord. Other organs were free of hemorrhage. The cause of death was a perforated gastric ulcer with diffuse peritonitis.

Comment

Central nervous system hemorrhage is a dreaded complication of coumarin therapy and calls for evacuation of the offending hematoma. Patients on anticoagulants may bleed into the epidural or subdural space or intracranially.[2-4] Bleeding can occur while the prothrombin time is at supposedly safe

---

*This case report has previously appeared as the subject of a Clinical Path Conference in *Minnesota Med* 49:145, 1966.

levels. Eight of the ten patients with coumarin-induced epidural hemorrhage reviewed by Spurney *et al.* had prothrombin times within the therapeutic range.[2] A diagnostic clue in patients with cord compression from epidural hemorrhage is xanthochromic cerebrospinal fluid with a decreased pressure and an increase in protein control (Froin's syndrome). Laminectomy and decompression after coumarin withdrawal and vitamin K infusion are the most effective means of therapy.

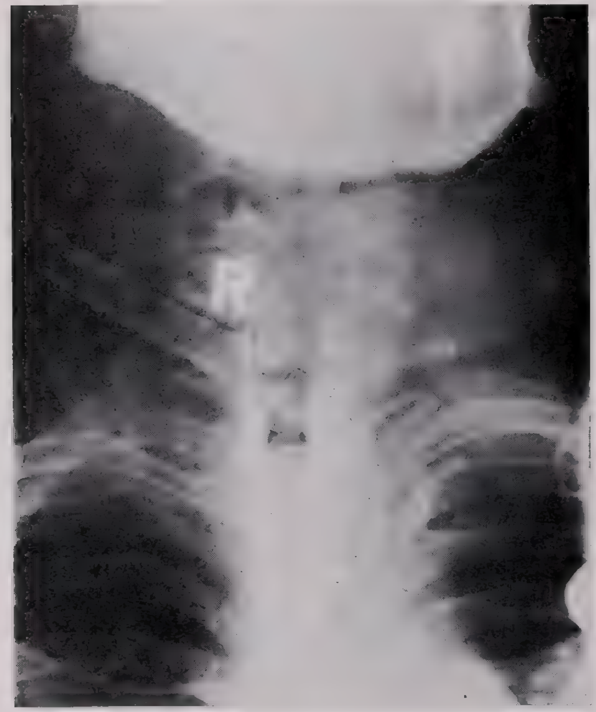

Fig. 1 — Myelogram showing complete obstruction of pantopaque at the level of the disc space between the 6th and 7th cervical vertebrae. The spinal cord is widened by external pressure. The lateral film showed anterior extradural compression.

Probable Hemoperitoneum

A 47-year-old woman was seen on August 12, 1965, with a one-week history of vague cramping abdominal pain and constipation. One day before admission she had experienced nausea and vomiting. She had been taking bisoxycoumarin for five weeks because of thrombophlebitis. On physical examination, her abdomen was soft, distended and silent. She complained of right upper quadrant tenderness, and the provisional diagnosis was subacute cholecystitis.

The hemoglobin was 13.8 gm.%, the white blood cell count 10,600 with 75 neutrophils, and the prothrombin time 71 seconds (control 13.5 seconds). Both the urine and vomitus registered a positive benzidine test for occult blood, and 25 rbc./h.p.f. were seen on urinalysis. The abdominal flat plate showed a non-specific ileus. Because of the possibility of a hemoperitoneum from anticoagulants, vitamin K_1 (Aquamephyton) was given. Within hours the prothrombin time dropped to 21 seconds. By the next day her pain had subsided, and she was expelling flatus. She was discharged four days after admission.

Comment

This patient's symptoms and course are in keeping with coumarin-induced peritoneal bleeding. The clinical picture of hemoperitoneum simulates intestinal obstruction because of cramping, obstipation, and vomiting.[5] The bowel sounds are depressed or absent, and tenderness may occur in any quadrant. The diagnosis is best established by needle aspiration of the peritoneum. The

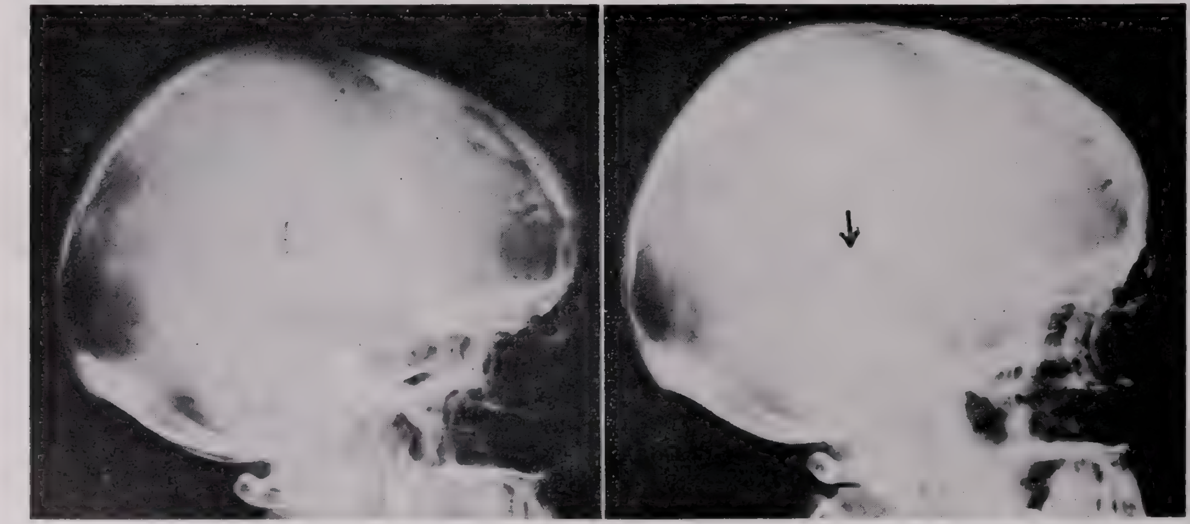

Fig. 2 — Lateral skull films demonstrating one cm. depression of pineal gland. The film on the left was taken on October 5 and the film on the right was done on November 30. The downward shift of the pineal led to evacuation of subdural hematomas.

free blood remaining may produce fever but usually leads to no other complications.

Probable Retroperitoneal Hemorrhage

A 36-year-old female entered the hospital on October 30, 1965, with a complaint of abdominal pain and back pain. One week before admission she had had a three-day illness with a fever of 105 and generalized muscle aches. Her symptoms were not improved by aspirin, and she saw a physician. He made a diagnosis of an acute viral illness, and she was given prophylactic dimethylchlortetracycline (Declomycin). Two days before her hospitalization, she had severe right lower quadrant pain radiating to the right costovertebral angle. The pain required morphine for relief and was thought to be due to a renal stone.

The patient had been hospitalized three weeks previously for coronary insufficiency and was placed on warfarin sodium (Coumadin) 5 mg. daily. She had been hypertensive for three years, but her blood pressure was easily controlled at 120-140/80-90 with hydrochlorothiazide and reserpine.

On physical examination she was in acute distress from severe abdominal pain. Her blood pressure was 140/90, and her temperature was 99.2. She displayed deep lower abdominal tenderness with mild rebound tenderness. An occasional bowel sound was heard. On pelvic examination tenderness was elicited high in the cul-de-sac.

Laboratory data included a hemoglobin of 12.0 gm.%, a white blood cell count of 10,000, a sedimentation rate of 92 mm/hr., a urine specific gravity of 1.015 with 4 rbc./h.p.f., BUN. of 17 mg./100 ml. and a prothrombin time of "greater than" 60 seconds (control 13.5 seconds).

The patient failed to pass urine for the first 24 hours. An emergency intravenous pyelogram was done, and no contrast material was seen in the calyces or bladder after four hours. A cystoscopy was performed, and indwelling ureteral catheters were inserted with immediate flow of urine. The urine obtained at cystoscopy was bloody. At this point, the patient's hemoglobin had fallen sharply to 9.8 gm.%, and she was given one unit of packed cells. The provisional diagnosis was retroperitoneal hematoma with ureteral obstruction and probable blood clots in the calyces. She was given 50 mg. of vitamin K_1 (Aquamephyton) on October 31 with a prompt decline in the prothrombin time to 16 seconds. For a week after the insertion of the catheter, urine drained mostly from the right kidney; the unequal drainage was attributed to clots in the left kidney. The drainage then equalized. The catheters were removed, and she was discharged on November 12.

Comment

Before her febrile viral illness, this patient's prothrombin time was well controlled. Did her illness or its treatment with aspirin and declomycin produce hypoprothrombinemia? Fever, salicylates, and broad-spectrum antibiotics are all known factors in producing a prolonged response to coumarin.[6,7] Although the mechanism of the effect of fever and aspirin on the prothrombin time is not clear, antibiotics act by interfering with the synthesis of vitamin K in the intestine.

The site of the patient's blood loss is guesswork. The fall in the hemoglobin from 12.2 gm.% to 9.8 gm.% indicates significant hemorrhage, and the retroperitoneal space seems a logical reservoir for a large amount of blood. Her complaints of costovertebral pain, the tenderness high in the cul-de-sac, and the prompt excretion of urine after the placement of a ureteral catheter add to the evidence from a retroperitoneal hematoma with ureteral obstruction. Retroperitoneal hemorrhage does not explain the roentgenographic picture of renal failure. The bloody urine obtained at cystoscopy could reflect parenchymal or calyceal hemorrhage.

Bilateral Subdural Hematoma

A 59-year-old widow was admitted on November 11, 1965, for evaluation of generalized severe headache. She had been hospitalized two months previously for vertigo. This was attributed to cerebro-

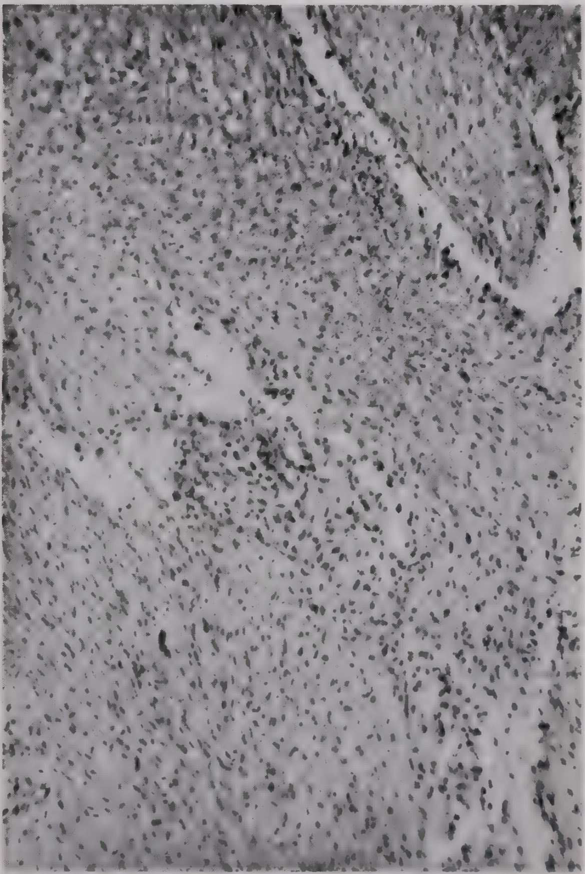

Fig. 3 — Low-power view of subdural hematoma showing fibroblastic proliferation. The histological appearance suggests a chronic subdural hematoma of at least three weeks' duration.

vascular arteriosclerosis. She was placed on bisoxycoumarin, 50 mg. daily. Her headaches began two weeks before admission and became steadily worse.

A neurological examination was negative, but the patient complained of persistent headache. Laboratory work included a prothrombin time of 21 seconds (control 14.2 seconds). The patient's headache was considered "functional," and she was treated with trancylcypromine (Parnate), trifluoperazine (Stelazine), and chloral hydrate.

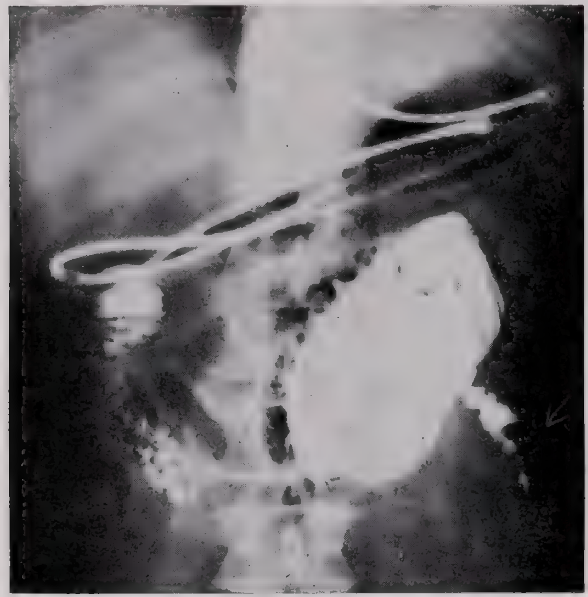

Fig. 4 — Small bowel contrast study on January 16, showing complete obstruction of proximal jejunum. The bowel wall around the obstruction is thickened and forms a soft tissue mass due to an intramural hematoma.

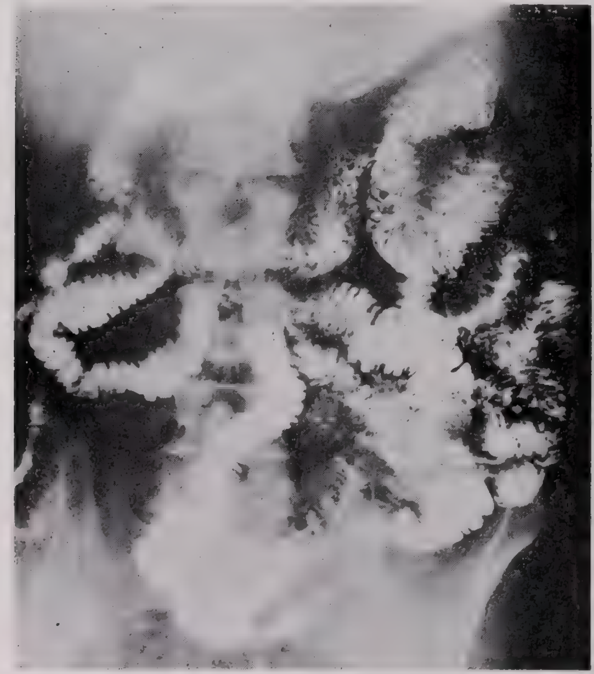

Fig. 5 — A repeat small bowel study on January 24, demonstrating resolution of small bowel obstruction with residual thickening of bowel wall and feathery mucosal pattern of the jejunum.

A lumbar puncture of November 23 yielded xanthochromic fluid containing 515 rbc./mm^3 and a protein of 104 mg./100 ml. A brain scan and carotid arteriograms were normal, but a skull film on November 30 showed definite depression of the pineal when compared to the previous examination of October 5. (Figure 2). On December 1, a bilateral craniotomy was performed with the removal of bilateral "subacute" subdural hematomas. Microscopically, the hematomas showed organization with fibroblastic reaction and fibrous tissue formation (Figure 3).

Comment

This patient illustrates a treacherous feature of therapy with coumarin compounds; viz., patients may bleed at ostensibly safe prothrombin levels. In a previous article, one of us (RLR) reviewed 15 patients with "spontaneous" subdural hematomas — seven with prothrombin times in the therapeutic range.[8] About 75% of patients with subdural hematomas usually have a history of trauma, but in anticoagulated patients subdural hematomas tend to be spontaneous or initiated by a minor event such as straining during a bowel movement.[8,9]

Intramural Hematoma of the Jejunum

A 55-year-old pharmacist entered the hospital on January 15, 1966, complaining of abdominal pain of four days duration. He had had a myocardial infarction in 1959 and had been placed on warfarin sodium (Coumadin). Between 1959 and 1960, he had had two episodes of skin purpura and was erratic in taking the drug and in having prothrombin determinations. For four days prior to his January 15th admission, he had experienced increasingly severe abdominal pain culminating in repeated vomiting.

On examination, he was pale and in distress from abdominal pain. The blood pressure was 120/80 and the pulse 110. The abdomen was distended with left lower quadrant tenderness and rebound tenderness. A mass was palpable in the tender area. The bowel sounds were high-pitched. Petechia was present over the legs.

The hemoglobin was 14.2 gm.% and the white blood cell count 15,100 with 65 neutrophils and 19 band forms. The urine contained 30-50 rbc./h.p.f., and the prothrombin time was 59 seconds (control 14.0 seconds). He was given intravenous vitamin K_1, and the prothrombin time dropped to 20 seconds within six hours.

An abdominal flat plate disclosed loops of small bowel with air fluid levels and a soft tissue density. An upper gastrointestinal series showed a soft tissue mass and an obstructed jejunum (Figure 4).

The patient was treated with nasogastric and then Miller-Abbott suction. He promptly improved, with resolution of the obstruction (Figure 5), but on January 24, his speech became slurred and his left side became paralyzed. He improved with heparin anticoagulation, but on January 29 went on to a complete left hemiplegia.

Comment

This patient's clinical symptoms and signs and radiographic picture are characteristic for intramural hematoma of the jejunum. Goldfarb, in reporting eleven similar cases and reviewing 24 from the literature, observed that: patients usually have a distended abdomen and high-pitched bowel sounds; the site of obstruction is almost always the jejunum; the obstruction is reversed in two to three days by withdrawal of anticoagulants, vitamin K infusion, and intestinal intubation.[10] The most characteristic radiographic sign, as seen in this patient and other reported cases, consists of a narrowed rigid segment of bowel with a serrated mucosal pattern, which is called the "crescent" or "thick bowel" sign.[11]

The cause of this patient's hypoprothrombinemia could have been excessive self-administration of warfarin sodium. He was a pharmacist, and seven of the ten "Dicumarol-Eaters" reported by Bowie et al. were connected with the medical profession in some way and had free access to anticoagulants.[12] Patients who consume anticoagulants without prothrombin time control are destined for hemorrhage. Lastly, this patient's stroke nine days after cessation of warfarin raises the spectre of "rebound hypercoagulatability" — a phenomenon which occurs seven days after stopping the drug.[13]

Paralytic Ileus — Bleeding Site Unknown

A 74-year-old retired white male entered the hospital on February 5, 1966, complaining of severe abdominal pain. His pain had started abruptly three days before when he had grabbed a stair rail after stumbling on the stairs. He had obstipation but no vomiting. He had been taking warfarin sodium for one month after an episode of cerebral ischemia.

On examination, his pulse, blood pressure, and temperature were normal. He had diffuse abdominal tenderness with slight distention and generalized rebound tenderness. The abdomen was silent. A 2-cm. ecchymotic area was noted on the abdominal wall.

Laboratory data included a hemoglobin of 12.6 gm.%, a wbc. of 12,300, a prothrombin time of 107 seconds (control 12.5 seconds), and 100-150 rbc./h.p.f. in the urine. A plain film of the abdomen showed large and small bowel distention and was interpreted as a paralytic ileus. A contrast study showed no obstruction of the intestine.

The patient was given 50 mg. of intravenous vitamin K_1, and a nasogastric tube was inserted. Within eight hours his prothrombin time had dropped to 18 seconds, and his abdominal pain was subsiding. By the following morning he was passing flatus. Two days after admission, he had a transient hematuria but no recurrence of abdominal symptoms. He was discharged nine days after admission.

Comment

Either bleeding into the mesentery or the peritoneal cavity could have produced paralytic ileus in this patient. The absence of changes in the jejunum and the lack of obstruction make an intramural hematoma unlikely. The response to vitamin K and intestinal intubation is a succinct testimonial to a statement by Hafner concerning coumarin-induced intestinal ileus: "This is a non-surgical problem — an awareness of its existence is imperative in order to obviate needless operative intervention."[14]

Hemorrhage into Metastatic Cerebellar Mass

A 67-year-old female was admitted on March 28, 1966, because of dizziness for two weeks and vomiting for one week. The dizziness occurred with a change in position of the head and was particularly noticeable when she stood after lying down. She observed she tended to veer to the right while walking.

On physical examination she was an alert asthenic

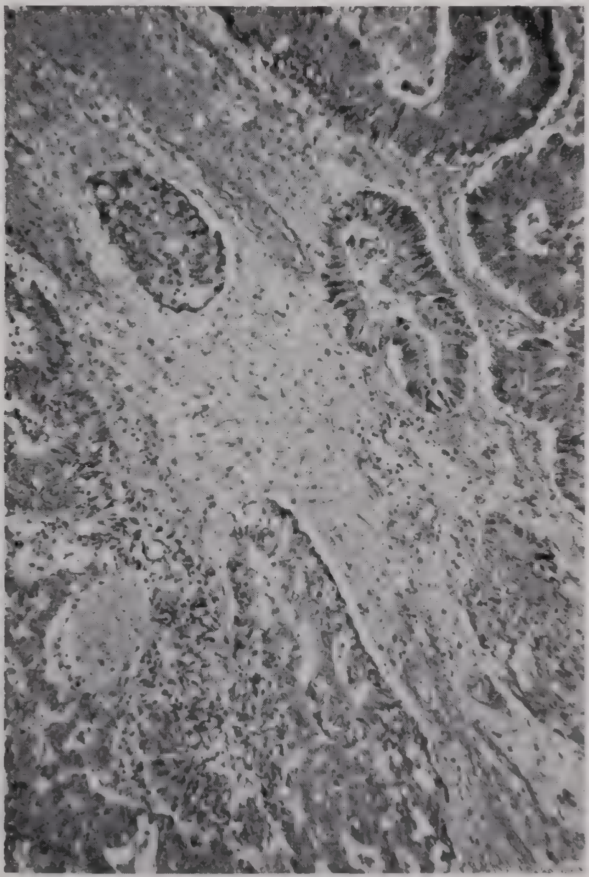

Fig. 6 — Section of cerebellar hematoma showing clumps of metastatic adenocarcinoma. H&E 100 ×

female. Her blood pressure was 162/90. A bruit was heard over the right carotid and subclavian arteries. The admitting diagnosis was arteriosclerosis of the right subclavian artery with resultant vertebral basilar artery insufficiency.

A spinal tap was done, and the fluid was clear with a normal protein content. On the second hospital day, she vomited repeatedly after a glucose tolerance test. On April 1, 1966, a retrograde brachial arteriogram showed sclerosis of the right innominate artery. On April 2, 1966, she was given 40 mg. of warfarin sodium and on April 3 she received 20 mg. of the drug. Her prothrombin times from April 2 to April 5 were 13, 17, 33, and 47 seconds. On April 5 she became lethargic and then lapsed into coma with cyanosis. She died on April 5.

At autopsy, a 4 by 4-cm. hemorrhagic mass occupied the cerebellum, and 50 ml. of blood were in the subarachnoid space. Microscopically, the cerebellum revealed metastatic adenocarcinoma cells floating in pools of red cells (Figure 6). The primary tumor was an annular, ulcerating carcinoma of the sigmoid colon.

Comment

This patient was given warfarin for presumed cerebrovascular insufficiency and four days later hemorrhaged into a cerebellar metastasis. Brain hemorrhage is the most frequent cause of death from anticoagulants; it accounted for 46 to 122 deaths in Russek's series[15] Despite the threat of fatal hemorrhage, coumarin therapy is established in patients with vertebral-basilar insufficiency. In a Mayo Clinic study, ischemic attacks stopped in 90 of 94 patients after starting anticoagulant therapy.[16] In the same study, 107 patients with vertebral basilar thrombosis had a mortality of 8 percent on coumarin as compared to 58 percent in 31 similar patients.

Ruptured Abdominal Aneurysm

A 78-year-old white male was admitted to St. Barnabas Hospital on April 9, 1966, with hematuria of four days duration and nasal bleeding of one day duration. He had been taking "various" drugs at home, including thorazine and acetosalicylic acid.

The patient had been in St. Barnabas in December of 1965 for cerebral vascular insufficiency. At that time there was loss of coordination of the left arm and leg. He also complained of shortness of breath after physical exertion. Neurological examination revealed no special weakness in either arm, and the reflexes were completely normal. After two days of bisoxycoumarin therapy, the patient was discharged with a prothrombin time of 29 seconds.

When admitted on April 9, the prothrombin time was 108 seconds, and intravenous vitamin K_1 was quickly given. By the morning of April 10, 1966, the prothrombin time was still 81, but nasal bleeding and hematuria had stopped and the patient was feeling better and alert. The hemoglobin was 12.5 gm.%. His urine contained numerous red cells. Ab-

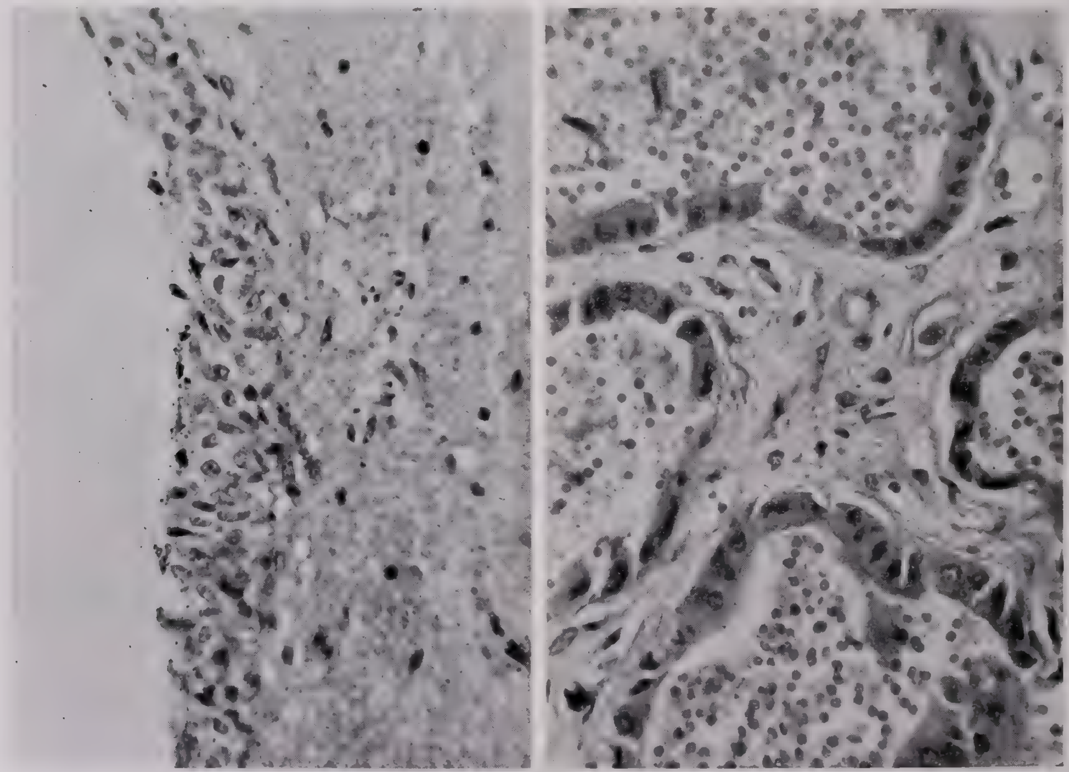

Fig. 7 — Photomicrographs showing blood in renal tubules and blood dissecting beneath the epithelium of the renal pelvis. H & E 430 ×. The patient had hematuria; and the left renal pelvis and bladder were filled with blood at autopsy.

dominal examination was considered negative, and the neurological examination was normal. By April 11, 1966, the prothrombin time was 22 seconds, and bisoxycoumarin was again given. On the morning of April 12 the patient had bloody urine again and passed two bloody stools. He complained of severe abdominal cramps and pain. Despite the administration of demerol, the abdominal pain became more severe. The abdomen was distended. At about 8 o'clock on the morning of April 12, the patient collapsed while in the bathroom and had convulsions. He was helped back to bed and after a short time responded to verbal stimuli. The blood pressure at 8:20 a.m. was 120/100, and the skin was cool and clammy. Aramine was given when the blood pressure became unobtainable. Examination showed hyporeflexia with positive toe signs, bilateral Babinski, a distended and silent abdomen. One examiner described the pupils as fixed and equal and the right arm as weak and flaccid with a definitely positive Babinski also on the right. The patient died at 8:30 p.m.

At autopsy the peritoneal cavity and root of the mesentery contained over 1000 ml. of blood. The source of the blood was a ruptured abdominal aneurysm. Other sites of bleeding were the wall of the sigmoid colon, the lung, and the renal parenchyma (Figure 7). The left kidney pelvis was filled with blood as was the bladder. The brain showed no lesions except for sclerosis of the cerebral vessels.

Comment

Anticoagulants were not directly responsible for this patient's death, but they contributed to it by clouding the true diagnosis and exaggerating the bleeding from the aneurysm. Bleeding itself can prolong the prothrombin time and should be searched for in the absence of a clear-cut cause of hypoprothrombinemia.[17] Patient reliability should be a prime consideration in prescribing coumarin drugs. The possibility exists that this elderly man, confused by his cerebrovascular disease or his sedatives, took an inadvertent overdose of coumadin.

Discussion

The word "dilemma" is rooted in the literature on anticoagulation. These dilemmas may be: complications are merely an extension of the therapeutic effect; bleeding can occur in the "therapeutic range"; the index of anticoagulant response — the prothrombin time — is often poorly controlled and, indeed, is expressed differently by different laboratories; anticoagulants are influenced by underlying diseases and by other drugs; and the indications for anticoagulants are controversial.

To these dilemmas could be added a clinical maxim: "Expect the unexpected." Patients on anticoagulants can and do bleed in any location: subdural space, brain, pituitary, pericardium, pancreas, adrenal, kidneys, retroperitoneal space, wall of the intestine, and rectus abdominis muscle; and they may present with such rare syndromes of medical progress as generalized clotting deficiencies, "purple toes" necrosis of the skin, and gangrene of the breast.[2,4,10,12,15,19-25] Recognition of these complications by the doctor can be life-saving for the patient.

What is the risk of anticoagulation? The answer differs with the observer. The authors of the authoritative textbook, *Pharmacological Basis of Therapeutics*, state that the taker of bisoxycoumarin has a 4% incidence of minor bleeding and a 2% chance of major hemorrhage.[6] Yet Keyes and his followers observed bleeding in 42% of their patients, and 13% were classified as major.[26] Tullock and Wright reported a 19% incidence of bleeding, but 11 of their 71 patients with bleeding required vitamin K or transfusions.[27]

Results from well-controlled studies of coumarin therapy probably did not reflect the experience of practicing physicians. In 1953, Russeck and Zohman sent a questionnaire to internists and cardiologists, and of 228 physicians replying, 104 had seen patients with serious complications and 122 deaths attributed to hemorrhage.[15]

The purpose of this report is not to discuss the tangled controversy of indications and statistical dangers but to highlight unexpected complications and why they occur. Giving coumarin drugs is not a simple matter of administering the drug and following the prothrombin time. The results of "prothrombin" tests differ, not only among various laboratories, but in the same laboratory.[28] This may be due to differences in diluents, in dilution curves, in the types of thromboplastin used, to modified technique, to technician errors, or to the times and differences of temperature used in incubating the plasma.[28]

Yet another controversy simmers as to whether the Quick prothrombin time measures the deficiency of factors responsible for bleeding.[29] Quick himself has countered these claims by asserting that the standard prothrombin time, properly performed, is adequate for control of coumarin therapy.[30] The papers referred to contain excellent discussions of the effect of coumarin drugs on the clotting mechanism and on the various coagulation factors.

The dilemma of the clinician is compounded by conditions and drugs which obscure and complicate anticoagulation. Fever, blood dyscrasias, hepatic dysfunction, renal insufficiency, hypertension and ulcerative gastrointestinal disease all increase the risk of bleeding. Indeed, hemorrhage is often the first sign of the existence of underlying disease.[31] Among drugs which alter the response of patients are steroids, salicylates, barbiturates, broad-spectrum antibiotics, and prophyl thiouricil.[32] Ulcerogenic drugs, such as cincophen, phenylbutazone, and reserpine, do not effect the prothrombin time but should be avoided to decrease the threat of gastrointestinal bleeding. The physician who prescribes anticoagulant should be aware of the effect of drugs and disease before deciding whether the expected benefits outweigh the potential dangers.

Summary

Eight patients were admitted to St. Barnabas Hospital from September, 1964, to April, 1966, with serious complications from coumarin therapy. The known site of hemorrhage in five patients was the spinal epidural space, the wall of the small intestine, the subdural space, the cerebellum, and an abdominal aneurysm, and in three, the suspected sites of bleeding were the retroperitoneal space, the root of the mesentery, and the peritoneal cavity. Three patients died; one was saved by exacuating a bilateral subdural hematoma; and four recovered after cessation of coumarin therapy and vitamin K administration.

Disordered Metabolism

Now, is it not a disgraceful state of affairs that a person who has had an excellent constitution should need to be carried about by other people owing to gout, or should be worn away by the pains of stone or colic, or of a bladder ulcerated by disordered humours (cacochymy). Is it not disgraceful that a person should, by reason of that extraordinary thing, arthritis, be unable to use his own hands, and should need somebody else to bring food to his mouth, and to perform his toilet necessities for him? Unless one were an absolute weakling, one would prefer to die a thousand deaths rather than endure such a life. — Galen

Augmentation Mammaplasty

JOHN B. ERICH, M.D.*
Rochester, Minnesota

SINCE THE subject of augmentation mammaplasty often gives rise to adverse criticism, one might wonder whether or not there ever is any acceptable excuse for performing this type of cosmetic surgery. Justification for such surgery seems dependent entirely on the patient's motives for wanting such alterations in breast contour. It is well to bear in mind that the underlying factors prompting a woman to seek the services of a surgeon for correction of a flat chest or underdeveloped breasts may appear unreasonable to many people but are perfectly rational to the patient herself. Although the motives often are obscure many women, when comparing their small breasts with those of their friends more generously endowed, feel sensitive and self-conscious. Many stable and well-integrated women can be embarrassed over a flat chest, and it is gratifying to observe the satisfaction which these individuals experience and the favorable personality changes which they often exhibit after a successful mammaplasty (Figures 1, 2, and 3). It therefore becomes evident that an augmentation mammaplasty is of much psychologic benefit in some cases of mammary hypoplasia.

It is true that the availability of padded bras and so-called "falsies" solves the problem for many women with hypoplastic breasts, but in some cases the use of such devices does not remove the emotional distaste for this imperfection in body contour. In these instances, nothing short of an augmentation mammaplasty will help the patient obtain inner security and self-esteem.

Unfortunately, in a great many cases, the desire for surgical enlargement of the breasts is prompted by motives far removed from physical attractiveness. I am referring to patients who foster the unrealistic hope that alterations in breast contour will solve everything from a nonexistent love life to the most involved marital difficulties; needless to say, nothing is farther from the truth.

---

*Mayo Clinic and Mayo Foundation: Section of Plastic Surgery.

Women who request augmentation mammaplasty can be divided into two categories: those who will benefit psychologically by this form of surgery and those who will not.

Indications

I have no hesitancy in recommending a cosmetic mammaplasty on women with hypoplastic breasts whose desire for surgery is prompted merely by an inclination to improve their physical appearance. Delving into the psychologic past of such an individual often reveals the fact that she has had a lifelong feeling of self-consciousness; her request for breast surgery involves nothing more than a desire for improvement in body contour, hoping thereby to eliminate her feelings of inferiority. In all such cases, an augmentation mammaplasty is especially helpful in giving the patient a sense of emotional well-being.

Such patients are not to be confused with the woman who has a deep-seated, almost pathologic sense of inferiority, which makes it impossible for her to cope with the emotional problems of everyday life, and who attributes such feelings of inadequacy entirely to small or unattractive breasts. Such a person often is of the opinion that an augmentation mammaplasty will give her an immediate sense of self-confidence. However, such is not the case, and the patient finds that after surgery her emotional pattern continues along the same old lines with no relief from inner conflicts and no increase in self-esteem.

Contraindications

Any woman with mental or emotional problems not related to the breasts but which the patient ascribes directly or indirectly to underdeveloped mammae should be discouraged from undergoing an augmentation mammaplasty; as a matter of fact, the surgeon should flatly refuse to operate on such a person.

Shattered Romance

In this category are women who, for various reasons, do not attract members of the opposite sex; however, if the breasts are surgically enlarged because of such circumstances, the patient is in for bitter disappointment when she finds that it has not

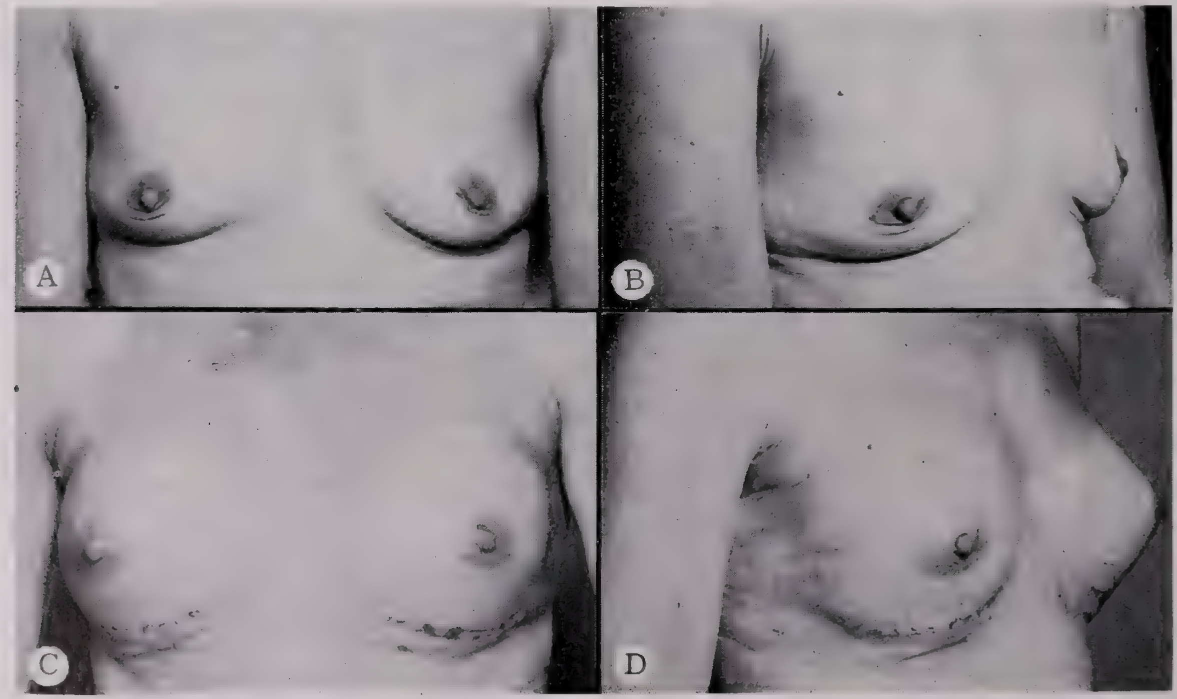

Fig. 1. Hypoplastic breasts. *A* and *B*, Before insertion of implants. *C* and *D*, After.

opened the way to romance. Then there are married women who believe that an augmentation mammaplasty will dissolve a whole host of marital difficulties, the most common of which are disinterest or unfaithfulness on the part of the husband. Needless to say, these operations not only do not relieve these unpleasant situations but actually compound the patient's problems. Apparently the causes of such difficulties are incomprehensible to the patient but become buried in a mass of inner conflicts and emotional upheavals. To such a person, the enlargement of the breasts seems to be the only means, or at least one means, of relieving her depressing and often insurmountable problems. She

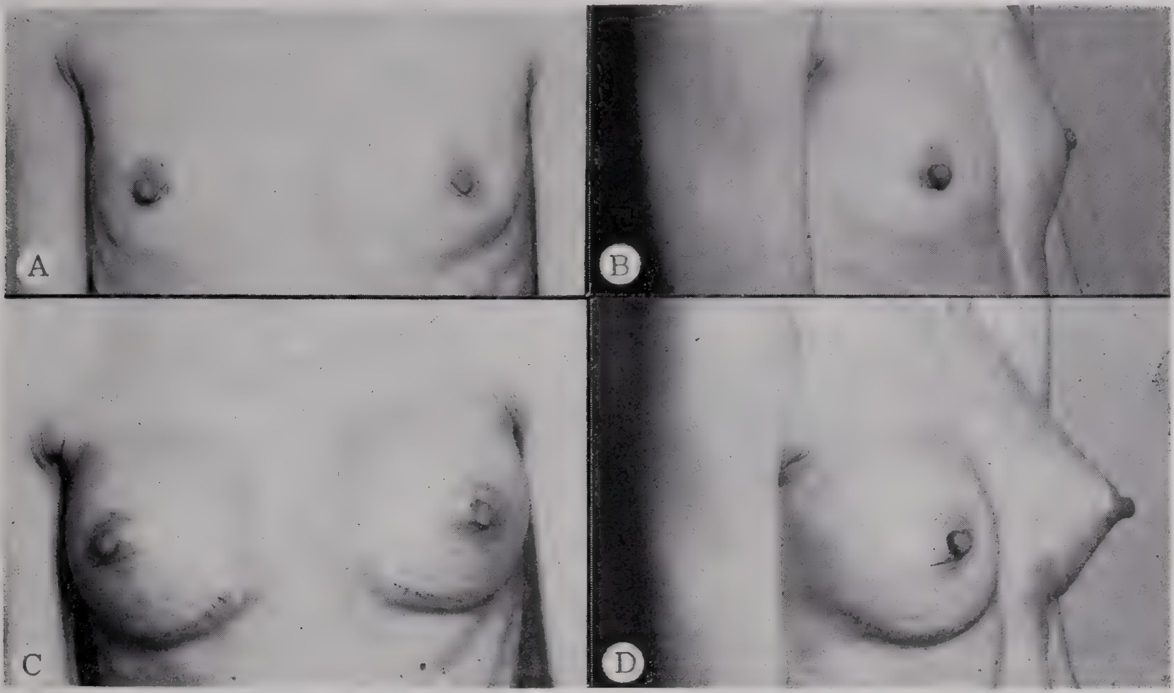

Fig. 2. Hypoplastic breasts. *A* and *B*, Before insertion of implants. *C* and *D*, After.

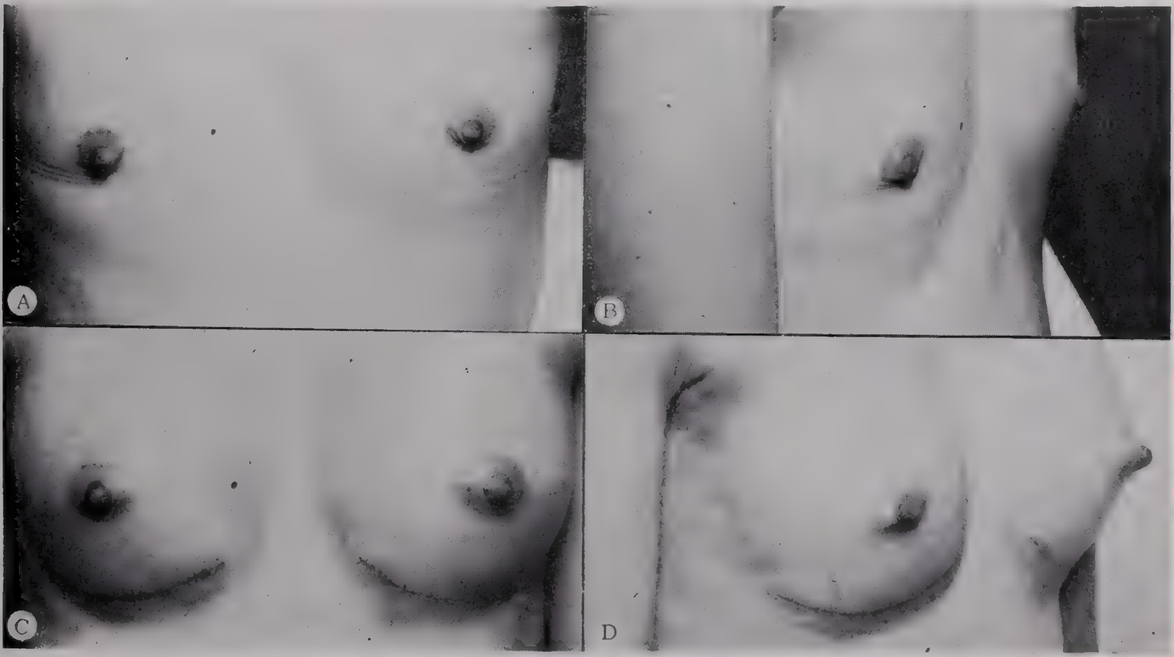

Fig. 3. Hypoplastic breasts. *A* and *B*, Before insertion of implants. *C* and *D*, After.

feels that enlargement of the breasts will improve her figure to the point where an unfaithful husband or an indifferent lover will take renewed interest in her, thereby avoiding the possibility of divorce or a broken love affair. Shattered romances and disillusionment in marriage, however, are among life's difficulties not solved by altering the contour of the breasts.

Pleasant Surprise

Many wives want this type of surgery performed without their husbands' knowledge and consent. Not infrequently, a wife wishes to undergo the surgical procedure when her mate is out of town, thereby hoping to surprise him when he returns. However, it usually is the wife who is surprised, because I have yet to encounter a disinterested or unfaithful husband who is overjoyed to find, when he returns home, that his wife has spent several hundred dollars having her breasts enlarged. Operating on such women leads to so many problems that most plastic surgeons refuse to perform an augmentation mammaplasty on any married woman without her husband's consent.

Psychopathic Personality

Finally, I would like to mention the fact that psychopathic individuals not infrequently seek alterations in breast contour for reasons not always apparent. Surgical enlargement of the mammary prominences solve nothing in such cases and can lead the surgeon into unpleasant situations. Even more distressing are the difficulties encountered when the unsuspecting surgeon performs a mammaplasty on a psychotic woman who seems normal before the operation but postoperatively reveals unmistakable evidence of her distorted mind.

From the foregoing discussion, it should be apparent that the psychologic aspects of patients wanting an augmentation mammaplasty are deep and complicated. If the surgeon is going to avoid difficulties in these cases, it is most important for him to realize that every woman who consults him in regard to an augmentation mammaplasty is not a fit candidate for this type of cosmetic surgery. He must explain in detail to the patient, and to her husband as well, the problems involved and the possible complications. In addition, he must not promise precise postoperative results which cannot always be surgically achieved. Furthermore, if the surgeon is unable to evaluate the patient's emotional background, he had better seek the services of a competent psychiatrist before performing the operation. Patients thus properly selected and warned against expecting too much or the impossible are going to be pleased with the final result and not disgruntled should a complication arise.

Methods

In general, there are three methods of enlarging the breasts at the present time: (1) transplantation of free dermal-fat grafts; (2) transference of submammary dermal-fat pedicle grafts; and (3) submammary insertion of plastic sponges or other plastic materials.

Free Dermal-fat Graft

When free dermal-fat grafts, usually obtained from the buttocks are employed to increase the size of the breasts, the results usually are unsatisfactory. Much of the fat in such transplants undergoes gradual liquification and absorption. In fact, practically all of the graft eventually disappears.

Dermal-fat Pedicle

Theoretically, inframammary dermal-fat pedicle flaps supply tissue which will not shrink or disintegrate because the graft has its own blood supply through the pedicle. Unfortunately, this method of augmenting the size of the breasts has some unfavorable features which make the procedure undesirable in most cases. Not only does it occasionally lead to some conspicuous scarring in the submammary region but inadequate mammary enlargement or poor contour occurs in many instances because an insufficient amount of tissue is available for transplantation. Most women who have a flat chest or insignificant breasts are thin and do not have enough subcutaneous fat to provide adequate tissue for satisfactory mammary enlargement.

Submammary Prosthesis

In regard to the third method of augmentation, that of utilizing plastic substances to build up the size of the breasts, there are now available plastic implants and materials that provide lasting and pleasing cosmetic results. A few years ago when enlargement of the breasts was accomplished by means of plastic sponges, complications were not uncommon. Often the sponge, after being impregnated with scar tissue, became excessively hard. Not infrequently, the contour of the operated breast underwent distortion due to the contracture of scar tissue in the sponge. Furthermore, these sponges occasionally acted as foreign bodies which were extruded or had to be removed. The newer plastic materials and implants, however, cannot be invaded by scar tissue and consequently do not tend to become hard and distorted. Some of these prostheses contain a liquid core which gives the breast a normal consistency on palpation. Finally, complications following use of these newer materials are extremely rare, provided that much care is given to asepsis during the surgical insertion of the implant.

Conclusions

There is a widespread desire for well-developed and neatly contoured bosoms in a large segment of our society. However, augmentation mammaplasty should not be an operative technique designed to please the whims of self-centered female exhibitionists, nor is it something intended to dissolve all sorts of personal or marital problems. On the contrary, it is a surgical procedure of much psychologic benefit in properly selected cases, bringing to the patient an inner sense of satisfaction. Although some of the older plastic sponges, when utilized to build up the mammary prominences, can lead to undesirable complications, the newer plastic materials and implants give excellent results in a large percentage of cases and can be recommended with few, if any, reservations.

Gulliver's Travels — Jonathan Swift*

Gulliver — On the Causes of War

"Sometimes the ambitions of princes, who never think they have land or people enough to govern: sometimes the corruption of ministers, who engage their master in a war in order to stifle or divert the clamour of the subjects against their evil administration. Difference in opinions hath cost many millions of lives: for instance whether flesh be bread, or bread be flesh: whether the juice of a certain berry be blood or wine . . . Neither are any wars so furious and bloody, or of so long continuance, as those occasioned by difference in opinion, especially if it be in things indifferent.

"Sometimes the quarrel between two princes is to decide which of them shall dispossess a third of his dominions, where neither of them pretend to any right. Sometimes one prince quarreleth with another for fear the other should quarrel with him. Sometimes a war is entered upon, because the enemy is too strong, and sometimes because he is too weak. Sometimes our neighbors want the things which we have, or have the things which we want; and we both fight, till they take ours or give us theirs."

I hate to be a kicker, I always long for peace, But the wheel that does the squeaking is the one that gets the grease. — Josh Billings

IT'S THE LAW

Doctor's Examination and Hospital-Record-History Admissible

Although an examining doctor's opinion as to a patient's condition based on the history of the case as given to him by the patient was inadmissible, because it might be a self-serving declaration, his opinion based on his examination of the patient and her case history shown in the hospital records was admissible, a Texas intermediate appellate court ruled.

The patient had suffered back injuries for which she sought to recover benefits under the Workmen's Compensation Act. The doctor, who examined the patient only for the purpose of testifying for her, stated his opinion that her condition had been caused by the injuries she suffered while at work. On cross-examination, he stated that in giving his opinion he had taken into consideration the history of the case as told to him by the patient. The doctor testified on redirect examination that his opinion, based solely on the patient's hospital records and his examination of her and disregarding the history of the case she gave him, was still the same.

The examining doctor could not state his opinion as to the patient's condition based in part on the history of the case as told to him by the patient because the history might have been merely a self-serving declaration, the court said. His testimony on redirect examination changed the situation, and the opinion stated at that time was admissible, the court ruled.

The compensation insurer argued that the doctor should not have been allowed to take into consideration, in forming his opinion, the case history set forth in the hospital records. The patient gave this history when she entered the hospital for treatment and surgery, a time when her main interest would almost certainly have been to get well and when she would have had very little motive to give a false or questionable case history, the court said. Since the case history was most probably accurate, the examining doctor could take it into consideration in forming his opinion, the court ruled.

Green Medicinals*

Herbs for the Liver

Ecclesiasticus said: The Lord hath created medicines out of the earth and a wise man will not abhor them.

Therapeutic herbs for the liver include bogbean, gooseberry, lilac, mandrake, snapdragon, and thistles. For anyone with a taste for gooseberries the following relish can be prepared.

Green Gooseberry Relish

Put into a preserving pan four quarts of green gooseberries, five pounds of brown or white sugar, and a little water. Boil until nearly cooked, then add another five pounds of sugar, a tablespoonful of powdered cloves, the same of powdered cinnamon, and a pint of vinegar, and boil till finished. It should boil three or four hours.—C. F. Leyel: Green Medicine

Nonspecific Ulcerative Colitis

Puerperal Disseminated Intravascular Coagulation as a Complication

M. H. SHORT, M.D.*
J. BURNS, M.D.
C. BROWN, M.D.
J. BRAINARD, M.D.
J. TEISBERG, M.D.
St. Paul, Minnesoa

A STATE OF hypercoagulability leading to disseminated intravascular coagulation has been stated to exist both in the pregnant patient[1] and in patients with nonspecific ulcerative colitis.[2] We have recently observed a patient who developed nonspecific ulcerative colitis during her pregnancy and later developed disseminated intravascular coagulation during the puerperium.

Report of Case

This 22-year-old Caucasian primipara had previously been in good health. There was no history of previous gastrointestinal illness and no family history of colitis or other gastrointestinal diseases. During the first two trimesters of pregnancy she did well.

Onset of Diarrhea

She subsequently developed intermittently severe diarrhea during the third trimester which responded poorly to symptomatic treatment but was not associated with dehydration, hematochezia or systemic toxicity. The patient entered the hospital in active labor but developed a uterine inertia. She became clinically dehydrated and was given intravenous fluids. Following this the membranes were ruptured artificially, labor resumed, and she delivered a normal female infant. The delivery was without incident and the patient tolerated it well.

Postpartem Course

On the *first postpartum day* she developed an ileus, nausea and vomiting and urinary retention. A Foley catheter was inserted and 850 cc. of urine was obtained.

On the *third postpartum day* abdominal x-rays showed the descending colon to be markedly distended. On the fourth postpartum day she developed diarrhea and a temperature to 102° F. rectally. The diarrhea became severe and the patient rapidly went into an electrolyte imbalance which was treated promptly and energetically. However, the diarrhea continued. Multiple stool examinations were done which failed to reveal any ova, parasites or pathogenic bacteria; but Charcot-Leyden crystals were seen and the stools were positive when tested for blood. On the seventh postpartum day, barium study of the colon was interpreted as showing ulcerative colitis. The patient was started on steroids.

On the *eighth postpartum day* while being ambulated she began dragging her right foot. Shortly after this she had a syncopal episode and became cyanotic and hypotensive. Her shock was treated successfully with vasopressors but the right leg became completely paralyzed. Chest x-ray was normal and EKG. showed only atrial tachycardia. Hemoglobin was 12.4 grams %, LDH 480 units and SGOT 50 units. Subsequently she became completely comatose. Neurological examination showed a right hemiparesis, distention of the veins of the right fundus and a deviation of the head and eyes to the right.

*Department of Pathology, Midway Hospital.

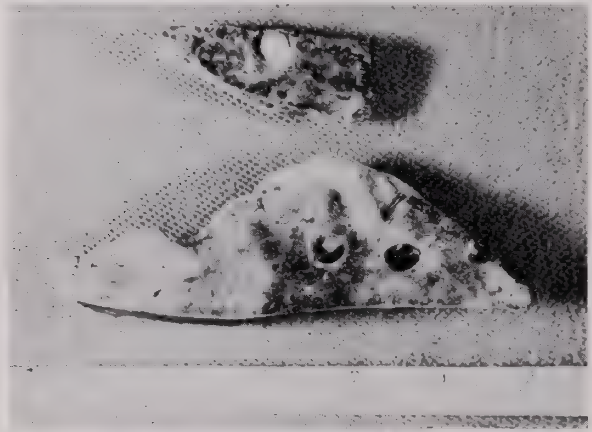

Fig. 1 — Thrombi in branches of hepatic vein with hemorrhagic infarction of liver.

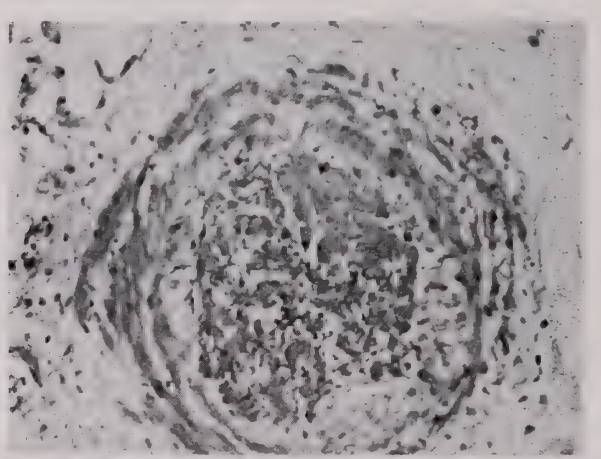

Fig. 2 — Thrombi in small vessels from cervical area (×100).

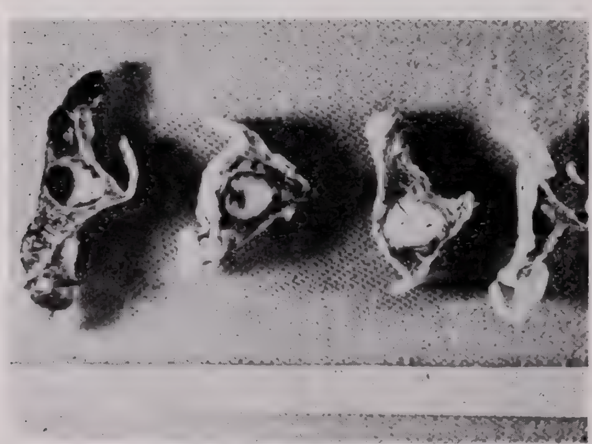

Fig. 3 — Thrombus in superior sagittal sinus.

There was a bilateral positive Hoffman reflex and a positive right Babinski, together with bilateral clonus.

Angiograms

Bilateral carotid angiograms were negative except for the finding of a very slow flow in the cerebral arteries with crossover blood flow into the middle cerebral vessels and filling of the basilar and vertebral vessels. That evening the patient developed seizures. On the tenth postpartum day ventriculograms were done. A very tiny left ventricle was seen on the x-ray films, but no gross shift was noted. A definitely increased cerebrospinal fluid pressure and a softening of the left cerebral hemisphere was also noted at this time. On the eleventh postpartum day the patient developed a thrombophlebitis of the right leg, became increasingly more comatose, and expired on the twelfth postpartum day.

Autopsy Findings

Thrombophlebitis

The significant postmortem findings included a thrombophlebitis of the right leg, a small pulmonary embolus in the right lung, and thrombi in many of the hepatic veins, with hemorrhagic infarction of much of the liver (Figure 1). Thrombi were also present in many of the small blood vessels throughout the body (Figure 2) and a thrombus was present in the left renal artery.

Ulcerative Colitis

Examination of the gastrointestinal tract revealed the typical findings of nonspecific ulcerative colitis involving the terminal ileum and all of the large intestine, with the cecum and ascending colon being more severely involved and the involvement decreasing distally. No uninvolved or "skip" areas were present. The genital organs showed only the findings of the postpartum state.

The Brain

Examination of the brain revealed a complete thrombosis of the sagittal sinus throughout its entirety as well as thrombi in the veins of the right frontoparietal area (Figure 3). A 6 × 3 × 3 cm. area of hemorrhagic infarction was noted in the left frontoparietal area (Figure 4) and smaller scattered areas of hemorrhagic infarction in the right frontoparietal and right occipital areas. Petechial hemorrhages were present throughout the pons, and marked tenting of the cerebellum was noted as evidence of herniation of the cerebellar tonsils. Other findings included an acute benign gastric ulcer and cholelithiasis.

Comment

The evidence for a hypercoagulability state during pregnancy includes the findings of an increase in activity of factors VII, X and fibrinogen plus an increase in factors VIII and IX in certain patients.[1] In addition, decreased fibrinolytic activity has been noted.[3]

It has been postulated, though not proven, that the traumatic event of delivery and separation of the vessels of the placental site may contribute to an augmented coagulability of the blood.[4] The evidence for a hypercoagulability state associated with nonspecific ulcerative colitis includes the finding of an excess of a material similar to factor VIII.[2] In view of the above facts it is interesting that more puerperal patients with nonspecific ulcerative colitis do not have disseminated intravascular coagulation. Possibly this is because most patients with nonspecific ulcerative colitis improve with pregnancy.[5] They may have exacerbations during the puerperium; but presumably there is enough time between delivery and exacerbation so that the hypercoagulability states do not overlap.

Puerperal intravascular coagulation frequently presents as a sagittal sinus thrombosis but may present as pituitary thrombosis (Sheehan's syndrome)* or thrombosis in veins of the extremities or the viscera. The thrombosis occurring in nonspecific ulcerative colitis is usually visceral, pulmonary, or in the extremities; but it may be cerebral as well. The sites of the thrombi are probably determined by local hemodynamics. The sagittal sinus, for example, has ideal conditions for thrombus formation, including slow blood flow and eddy currents caused by some of the posterior cortical veins entering in a direction opposite to the direction of the blood flow in the sinus.

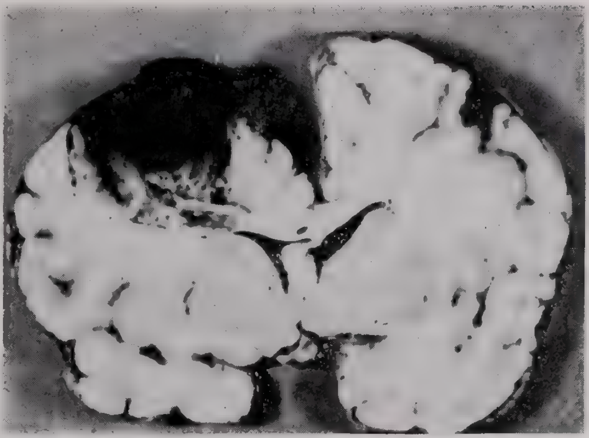

Fig. 4 — Hemorrhagic infarction of left frontoparietal area.

In addition it has been postulated (but never proven) that labor and delivery may cause damage to the walls of the sagittal sinus,[6] as this sinus is affected more frequently in puerperal patients than in others. In view of the above findings pregnant patients with nonspecific ulcerative colitis should be subjected to careful observation during labor, delivery and the puerperium. Dehydration should not be allowed to occur. If any signs of vascular thrombosis occur, they should be vigorously treated. Because of the risk of disseminated intravascular coagulation and a "consumptive coagulopathy" heparinization would seem to be the treatment of choice.

Summary

A case of disseminated intravascular coagulation in a puerperal patient with nonspecific ulcerative colitis is reported. Evidence from the literature suggests that the disseminated intravascular coagulation is due to a state of "hypercoagulability" which is secondary both to the nonspecific ulcerative colitis and to the puerperal state. It is suggested that puerperal patients with nonspecific ulcerative colitis who have severe symptoms during their pregnancy or immediately post partum be watched closely for signs suggestive of intravascular coagulation, especially as evidenced by central nervous system deficits.

To the Young Practitioner

What shall I say of the personal habits you must form if you wish for success? Temperance is first upon the list. Intemperance in a physician partakes of the guilt of homicide, for the muddled brain may easily make a fatal blunder in a prescription and the unsteady hand transfix an artery in an operation. Tippling doctors have been too common in the history of medicine. Paracelsus was a sot, Radcliffe was much too fond of his glass, and Dr. James Hurlbut of Wethersfield, Connecticut, a famous man in his time, used to drink a square bottle of rum a day, with a corresponding allowance of opium to help steady his nerves.

Sheehan's Syndrome*

(Postpartum Pituitary Necrosis Syndrome)

In 1937 Sheehan emphasized that during pregnancy the pituitary becomes enlarged but that during childbirth, its blood supply becomes diminished and it is particularly susceptible to thrombosis.

If a woman suffers from severe hemorrhage, collapse, or shock at the time of delivery or in the postpartum period, she should be observed for subsequent signs and symptoms indicating pituitary necrosis, which may manifest as a multiglandular deficiency and possibly myxedema. Pallor, asthenia, apathy, atrophy of the breasts with loss of areolar pigment, inhibition of lactation, loss of pubic and axillary hair, and genital atrophy are most of the presenting signs. Amenorrhea may be temporary or permanent. Hypoglycemia is usually found and may be sufficient to produce severe symptoms.

Treatment should be directed to the polyglandular deficiency and failure. If the syndrome is not recognized and substitution therapy not instituted, death may occur.

On Quaffing

If you are loose in your ways you won't improve them by getting tight. — The Schemer

Skin Replacement on the Extremities*

LYLE V. KRAGH, M.D.
Minneapolis, Minnesota

OCCASIONALLY FOLLOWING the extensive losses of tissue on the extremities, associated with automobile, industrial or thermal accidents, coverage of the exposed area is necessary to obtain healing of the wound.

Free Skin Grafts

In the avulsion type accident, where skin and subcutaneous tissue are lost, the wound may often be debrided and a split-thickness graft applied immediately to close it. If after debridement, however, there is still tissue of questionable viability, it is better to dress the wound for several days until a satisfactory granulation bed is present.

Temporary Graft

Coverage of extensively exposed tissue of the hand, wrist, ankle or foot with thin free grafts may be a temporary though important step in the final repair.[3] With considerable loss of skin and underlying tissue, fixation of tendon or joints in the dense scar often occurs. Occasionally, after allowing a scar to soften for several months, function of the contracted member can be improved by release of the constricting scar and application of a thick graft to the skin defect.[1]

Protection of the Graft

Elevation of the leg is most essential during the postoperative period in order to reduce fluid accumulation under the graft. After the graft has become adherent with primary healing, it must be protected by elevation of the resting extremity and supported by the use of an elastic bandage when the leg is in a dependent position. Such an elastic support should be worn from three to six months postoperatively. If elastic support is not worn, the stasis may result in cyanosis, blistering and loss of the graft. Healed free grafts have reduced sensation, are fragile, and should be protected. This includes cleanliness and avoidance of injury from work or poorly fitting shoes. The patient may be able to wear a larger soft shoe or one with wool fleece-lining to minimize rubbing on the graft. Special attention should be given to possible blistering of the graft if one-day-a-year sports such as skating or hunting are indulged in. Free grafts have a wider area of usefulness for children than for adults who require a pedicle flap.[7]

---

*Presented at the Minneapolis Surgical Society meeting May 3, 1965.

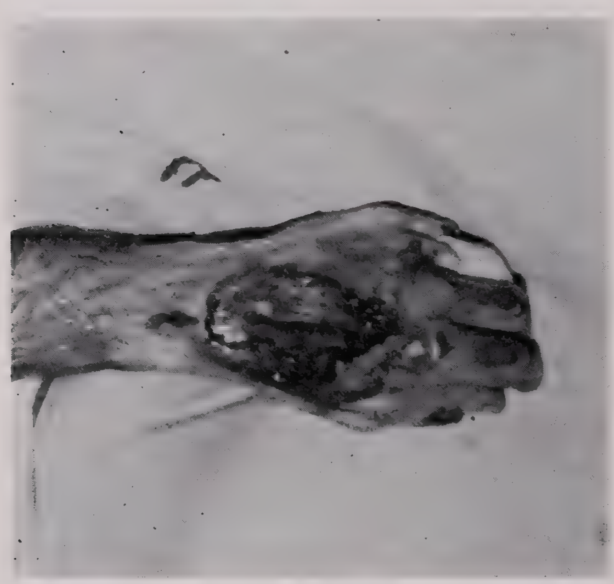

Fig. 1-a — Grinding wheel injury to dorsum of left hand and thumb. Photograph a few hours after injury. There is loss of skin, subcutaneous tissue and paratenon with tendon bare across base of wound.

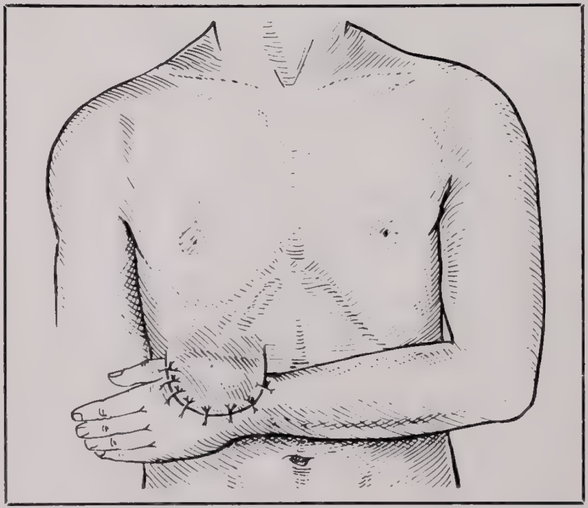

Fig. 1-b — Following debridement, an abdominal pedicle flap was elevated and sutured over the left hand wound. A free skin graft was applied to the abdominal wall defect. The pedicle flap was severed from the abdomen in two stages with final detachment after 25 days.

Pedicle Skin Grafts

Free skin grafts alone are often not satisfactory; what is required is excision of the scarred area and coverage of the resulting defect with a thick pad of durable skin and subcutaneous fat attached to a pedicle. After the area has been covered with nonscarred skin, future reconstructive features such as tenolysis, tendon grafts, nerve grafts or bone surgery can be carried out with better expectation of improvement.

Elective Procedure

Generally speaking, pedicle flaps are performed as elective procedures after the original wound has healed by secondary epithelization or by free grafts. Following the healing and control of the local infection, and perhaps after a period of appropriate splinting or physiotherapy, the definitive reconstruction can be planned and a pedicle flap used to provide durable skin to cover the involved area.

Upper Extremity Pedicle

A local rotation or sliding flap may occasionally be used for small upper extremity defects; often, however, the large size of the defect precludes use of the pedicle flap

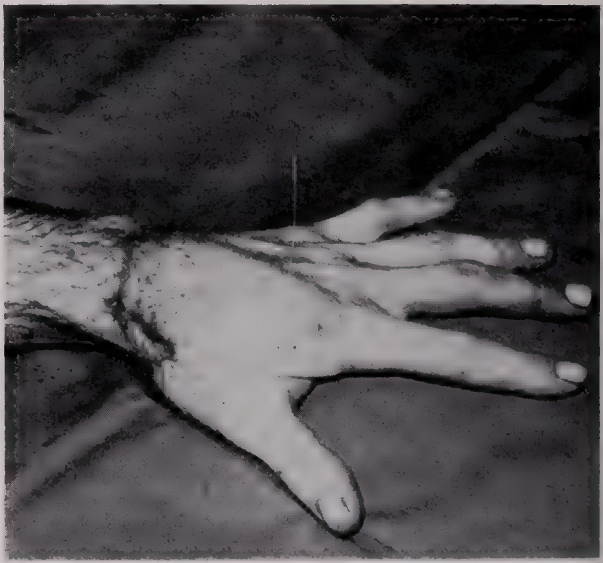

Fig. 1-c — Photograph 11 months after injury. There is normal function of the thumb and index finger.

adjacent to the defect. For upper extremity reconstruction, a source of relatively hairless skin can be found on the anterior chest or abdominal wall. Tube pedicle flaps are ideal; but often a quicker, more satisfactory reconstruction can be accomplished with an open flap.[4] The flap must be patterned so that it will be adequate in size, with attention directed to preserving the inflow and outflow vessels. If the base of the pedicle is narrow in relation to its length, elevation is more safely carried out in stages about one week apart. Following complete elevation, if the flap circulation is satisfactory, the recipient defect can be freshly excised and the flap skin sutured over the defect. The area from which the flap is raised and the exposed part of the undersurface of the flap should be covered with a free skin graft. Following flap approximation to the extremity, extensive taping will usually provide required immobilization to prevent disruption during movement or sleep. The flap will usually receive its new vascular supply in three to four weeks, and severance of the nourishing pedicle is then possible.

Lower Extremity Pedicle

Lower extremity pedicle flap repairs usually require several operative steps for their completion. For this reason, pedicle flaps are seldom recommended for areas which are open and locally infected, when the wound can be temporarily healed with free grafts.[2] In the lower leg and foot, there is usually little opportunity to use an adjacent sliding

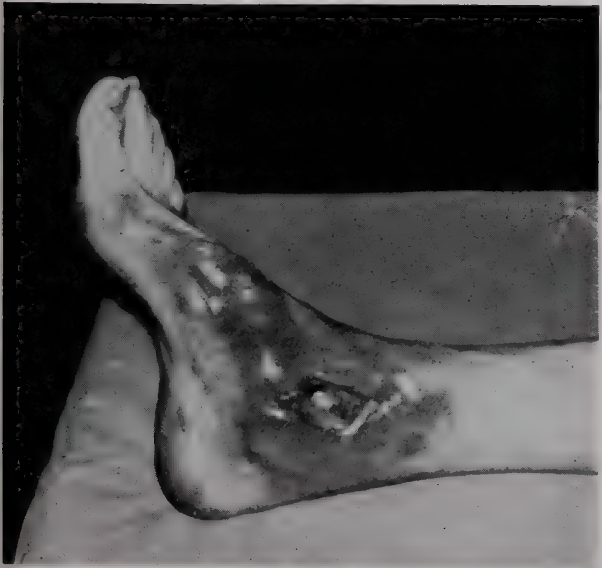

Fig. 2-a — Old post-traumatic injury to the right foot and ankle region. There has been breakdown of the previously skin-grafted area and there is exposure of the ankle joint.

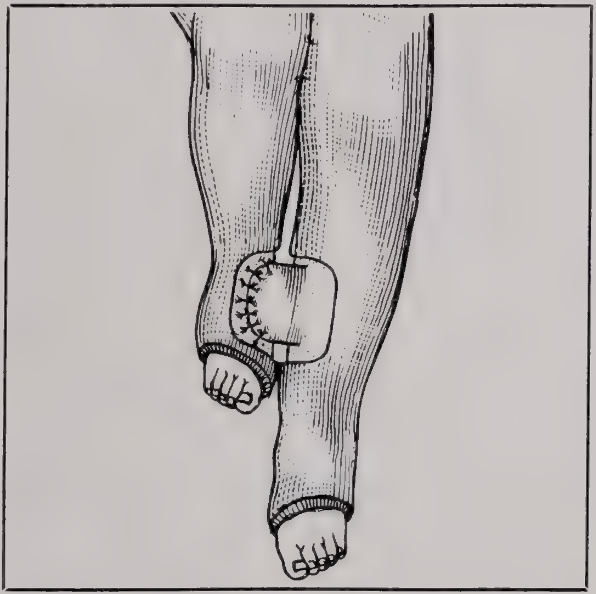

Fig. 2-b — A pedicle skin flap was prepared on the opposite calf by gradual elevation of the flap in stages (delaying procedure). The thin atrophic skin and the ulcer on the right foot were excised. The pedicle flap was sutured to the defect and the casts positioned and held to prevent tension on the pedicle. The flap was detached from the calf and fitted to the foot defect five weeks later.

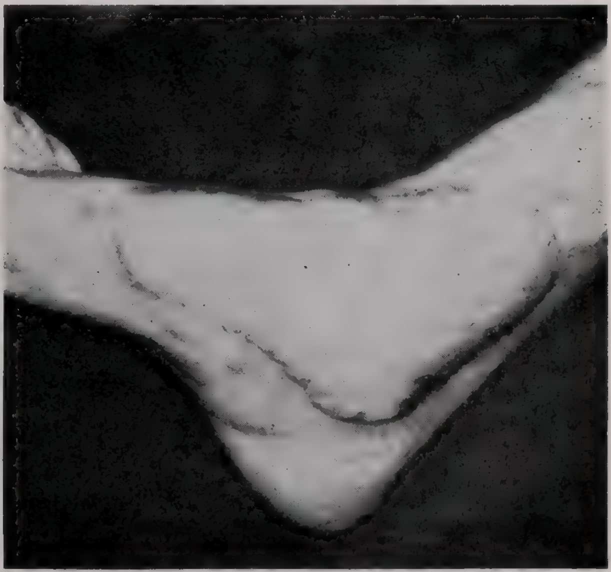

Fig. 2-c — Photograph of right foot 14 months after cross-leg flap procedure. There is normal ankle motion and no destruction of the ankle joint. The area has remained healed and the overlying pedicle flap skin has tolerated minor injuries of daily work.

or rotation flap. Therefore, the required thick pad of skin must be obtained from a less important area on the body (a calf — cross-leg flap; a thigh-cross thigh flap; a flap from abdomen via a wrist carrier). These procedures are exacting; each step must be carried out in detail. Whereas an abdominal flap may often be elevated and transferred to the hand primarily, the necessary dimensions and direction of a calf pedicle in a cross-leg flap procedure may preclude this. The circulation from the edges and undersurface of the flap must be cut off gradually over a period of weeks, redirecting the circulation all through the hinge. After these initial preparatory delaying procedures, the flap can be elevated entirely, as it should then have a satisfactory circulation to tolerate transferring it to the defect on the opposite lower extremity. Tension on the transferred flap is prevented by holding the legs attached to each other with well padded casts. The pedicle is maintained in this position for four or five weeks for the skin to receive vascularization from the foot[5,6] so that gradual cutting off of the nourishing pedicle can be carried out (Figure 2-b).

Pedicle for Exposed Bone, Fractures and Joints

If there is tissue loss over a bone or over a compound fracture, and if periosteum is still present, granulation will cover the area and it can be closed with a free graft. If periosteum is destroyed and granulations do not grow over the bone, drill holes or decortication of the bone may be necessary before granulation will emerge. In the lower third of the tibia this set of circumstances often leads to nonunion of the tibial fracture and the thin atrophic skin or graft immediately overlying the fracture site. Here a thick pad of skin will probably be required prior to bone grafting the tibia. Open joints may be impossible to close by any free graft or local flap. Hence a pedicle flap may have to be applied directly over the open joint or an infected wound in order to obtain closure.

Flap Coverage

On occasions an injury will exist which is very deep and involves important structures but which is localized to a small area and can be converted to a relatively clean surgical wound. If the periosteum or paratenon is lost or a joint is exposed, immediate closure of the wound is desirable but can not be accomplished with a free graft. If such a wound can be closed by a flap, fixation or loss of exposed tendons can be avoided.

Undermining the edges of the wound or use of a local rotation or sliding flap is simplest. However, on the extremities there is often not enough adjacent skin to be advanced across small defects. A pedicle flap elevated immediately from the anterior abdominal or chest wall may be used to cover small upper extremity losses, but such application must be used only with consideration of the eventual reconstruction. Immediate flap repairs can occasionally be employed safely in the thigh or leg but rarely should be used for defects at the ankle or foot.

In a hand with deep injuries about the proximal or middle joints the intricate extensor mechanism may be so badly damaged that obtaining a functioning finger is impossible. Occasionally this useless, numb finger can be used as a flap by filleting out the bones and tendons and utilizing the skin as a perfectly vascularized local pedicle flap to provide skin in a scarred contracted area. This is particularly true in the web space between a thumb and the first opposable finger. Likewise, in an acute hand injury the skin from a finger which cannot be salvaged can often be used to cover adjacent areas of lost tissue. The filleted toe may likewise be useful for local skin coverage.

Postoperative Care

After a skin flap is successfully transferred to the upper or lower extremity, it must be gently supported for several months with elastic dressings and protected from stasis with periods of elevation; in addition, the transferred skin has reduced sensation and must be guarded from injury. The limb with the successfully transferred flap must have the same meticulous care as a free graft. After several months the successfully transferred flap becomes more durable and will tolerate reconstructive procedures, removal of excessive underlying fat and tailoring of the skin edges.

Limitations of Pedicle Flaps

If prolonged immobilization of the area is required, these procedures may not be applicable in the very young child or the elderly arthritic patient. The long period of cast immobilization of lower extremities is poorly tolerated in patients past 55 years of age, in arthritics, or in patients with obliterative vascular disease, lower extremity venous disease or neuropathy.

In contrast, pedicle flaps in the upper and lower extremities of young healthy persons can be transferred quite rapidly and safely. In this type of patient a pedicle flap is satisfactory for covering areas about the hand, the lower leg or the foot, which would otherwise be unstable and undergo repeated ulceration.

Conclusions

Some useful reparative surgical procedures for traumatic soft tissue losses of the hand, leg and foot are presented. Where possible, the wounds should be initially healed by free grafts or epithelization. If free skin graft repairs are unstable, a pedicle flap of skin to cover the defect may be useful. The use of local and more distant pedicle flaps in the upper and lower extremity is presented.

Dr. Benjamin Winslow Dudley

The Lexington Intelligencer, December 9, 1836, considered Dr. Benjamin Winslow Dudley, of the Transylvania Medical College, the first surgeon in the West to remove a cataract of the eye. During his long surgical career he was said to have made over two hundred lithotomies with only four per cent mortality; more than one hundred of these were done before a single death was recorded. The Kentucky Gazette for April 11, 1827, reported three lithotomies performed by him in one day. Dr. Dudley also successfully ligated the subclavian artery for axillary aneurysm in 1841. In 1828 he published a report of five successful cases in which he had trephined the skull for the relief of epilepsy due to pressure on the brain. He was probably the first surgeon in the United States to perform this operation. Dr. Dudley was among the first doctors of the Middle West to discard the lancet; the stress which he laid upon the use of boiled or boiling water in surgery at that early time is worthy of comment. He emphasized preparatory treatment, to which he was more inclined to attribute his success than to his superior skill.*

Some people are always grumbling because roses have thorns. I am thankful that thorns have roses. — Alphonse Karr

Music and Medicine

Maladies of Musicians

As early as 1700 Ramazzini, who studied occupational diseases, stated that singers and wind-instrument players were subject to hernia and to hemorrhages in the chest. During the eighteenth and nineteenth centuries other observers' notes and records resulted in a more inclusive and comprehensive assessment of diseases peculiar to vocalists and instrumentalists.

"The professional musician uses only skilled methods in producing sounds; these methods entail a continual drain on his physical and mental abilities, and illnesses often result which are peculiar to his profession. *Nervous exhaustion,* for example, caused by a muscle spasm in neuromuscular fatique, will appear in the pianist and in the drummer. *Emphysema* of the lung is seen in both the singer and the hornblower. *Muscle fatigue* and finger sores arising from pressure on the cutaneous tips of the fingers are common to the guitar player. The hornblower may have a *hypertrophy of the abdominal muscles,* which can result in a relaxed abdominal wall. *Muscle spasms* or cramps occur at the area of the nerve endings in the fingers of pianists and organists. Zither players have the same *neuro-muscular spasms* and hypersensitivity in the left hand. In string players, especially violinists, spasms are frequent in the left thumb and forefinger and the right thumb and forefinger. The flute player may develop a spasm of all the fingers, the drummer one of the thumb and wrist, the violinist one of the right deltoid muscle because of the elevation of the bow. Hornblowers have muscle spasms of the lips and tongue muscles; singers suffer from various muscle strains. Harp players may develop spastic muscles of the legs from holding the harp between the legs. Even the director is not immune; he may have a mild spasm of the shoulder and right arm muscles. In addition there is apt to be generalized fatigue of the eyes and ears and central nervous system of all musicians when they have been musically active for a time."*

Some revealing articles in older medical journals provide specific focus on a few such disorders. For example, a monograph, *Vitiligo of Upper Lip in Players of Wind Instruments,* appeared in a 1943 issue of Archives of Dermatology; in 1885 one issue of the British Medical Journal included a discourse, *Digital Tenotomy in Pianists;* an 1899 issue of the International Clinician presented a treatise, *Indurated Sore of Lower Lip in a Cornetist;* and the Memphis Medical Monthly in an 1899 issue contained an article, *Chorditis Tuberose, or Singer's Nodule, Some Desultory Remarks Thereupon.*

Micro-adults

Children are not simply micro-adults, but have their own specific problems. — Bela Schick

Spontaneous Rupture of the Splenic Artery

Probably Due to Aneurysm

ARNOLD O. SWENSON, M.D.
JOHN M. RUNQUIST, M.D.
Duluth, Minnesota

SPONTANEOUS RUPTURE of the splenic artery during pregnancy, probably due to aneurysm, is a rarity,[1,2] and this case is added to the fewer than thirty cases which have been reported in the literature to the present time.

Rupture of an aneurysm of the splenic artery, or traumatic rupture of the spleen, is a serious complication, particularly when associated with pregnancy. The fortuitous* outcome of this case is undoubtedly due to prompt surgical intervention and blood replacement.

Case Report

This 28-year-old white female, gravida VIII, para VII, in her 36th week of pregnancy, was admitted to St. Luke's Hospital on February 15th of this year. She gave a history of developing an acute pain in the epigastrium and in the left flank while bending over emptying the lower shelf of the refrigerator. The pain was so severe that she fainted, but she recovered consciousness shortly afterwards and was able to go to the telephone and summon help. She denied any trauma associated with this onset of pain.

Her chief complaint on admission was severe pain in the epigastrium and below the left costal margin, and she was much more comfortable lying on her right side.

Her past history was essentially negative except for her pregnancies, all of which had been relatively normal, with uncomplicated delivery of seven term children. Her present pregnancy had been relatively normal, with no elevation in blood pressure. Urinalyses had been normal. She had been treated for a mild secondary anemia, which responded to iron therapy.

Physical and Laboratory Findings

Her blood pressure was 110 systolic, 70 diastolic; her pulse was 72 and her temperature 97.6°. The hemoglobin on admission was 9.8 gm. and the white count was 17,500. Serum amylase on admission was reported as 32 units. Her total serum bilirubin was .8, with the direct bilirubin .25 and the indirect .55. Urinalysis was normal.

Fetal heart tones were present but rather indistinct; the upper abdomen seemed to be mildly distended, with slight rebound tenderness. The uterine musculature appeared much firmer than usual.

Progress

She was given 50 mg. of demerol for relief of pain, and for the next four hours she was observed carefully in the obstetrical suite. About four hours later, while being examined by one of us, she suddenly went into acute shock. Her blood pressure dropped from 112/72 to 56/0. Her pulse was imperceptible and the fetal heart tones disappeared. She was given a unit of plasma followed by two units of blood when it became available. It was felt at that time that we were dealing with an abruptio placentae, as the uterus seemed to become quite distended and very hard, and with the disappearance of the fetal heart tones it seemed that we were dealing with retroplacental hemorrhage.

---

*See Test Your Word Score Page 1719.

Operative Findings and Procedures

The patient was taken immediately to the operating room and a laparotomy was performed. On opening the abdomen through a midline incision at the level of the umbilicus, about 2000 cc. of blood was found in the abdominal cavity. The source of the bleeding was not immediately determined because of the size of the uterus. The uterus was opened through a classical section incision and a stillborn fetus delivered. There was no retroplacental hemorrhage, although there was evidence of placental separation.

The wound in the uterus was rapidly closed, and with the decrease in the size of the uterus the abdomen could then be explored. The hemorrhage was found to be coming from the splenic pedicle, and there was no evidence of rupture of the spleen or laceration of the capsule.

A splenectomy was done as rapidly as possible. The original incision was extended about two inches above the umbilicus. The surgical procedure was not too difficult because of the relaxation of the abdominal wall following the decrease in size of the uterus. The splenic pedicle was clamped and the spleen was removed. The splenic pedicle was infiltrated with blood and it was apparent that the original bleeding had occurred into the lesser omental cavity, as considerable blood had infiltrated into the gastrocolic omentum and even into the omental layers.

The splenic pedicle was tied en masse with No. 2 chromic catgut, and then the vena brevia were ligated separately. Following irrigation of the peritoneal cavity the abdomen was closed.

The patient received a total of 3500 cc. of blood, 250 cc. of plasma, and another 200 cc. of dextran. She made an afebrile, uneventful recovery, and was discharged on her ninth hospital day. She was readmitted a week later with evidence of embolic phenomena in the left chest, which responded to therapy normally, and she was discharged five days later in good condition.

Pathologic Findings

A stillborn fetus weighed 6# 8 oz. and showed no abnormality. The placenta was not abnormal. The spleen weighed 240 gm., measured 4½ × 9 × 5 cm., and showed evidence of chronic passive congestion. There was a hemorrhagic area in the hilus which apparently resulted from the blood dissecting upward from the pedicle.

Discussion

As is frequently true in cases where the spleen is removed as an emergency procedure, no evidence of aneurysm could be documented. In most of the cases where an aneurysm of the splenic artery has ruptured, the aneurysm has been demonstrated at post-mortem examination. I am sure that if an aneurysm was present in this case, such evidence was destroyed by clamping the pedicle and removing the spleen.

A. J. Tomsykoski et al.,[3] reporting in the American Journal of Obstetrics and Gynecology in December 1953, summarized 28 cases of aneurysm of the splenic artery associated with pregnancy. Out of 28 patients, only two survived; in both instances survival was due to prompt surgery. There were two fetal survivals.

The symptom complex of epigastric and left upper quadrant pain was present in all the cases reported, and in none of the 28 cases was the true diagnosis made. Usually, rupture of the uterus, premature separation of the placenta, or other catastrophes related to ruptured viscus, was the diagnosis made. The incidence of traumatic rupture of the spleen[4] is now rising, due to the number of automobile accidents that occur, and pregnancy is a complicating factor in the treatment of the injury.

Lyons et al.,[4] of Mt. Sinai Hospital, reported 28 cases of rupture of the spleen. There were 15 deaths, the first eight of these reported before 1880. Excluding these fatalities, there were seven deaths in 20 cases. Further analysis of the 28 cases showed that of 16 patients operated upon, three died. All seven of the patients with traumatic rupture were operated upon and all recovered.

It is evident from the above report that early diagnosis of an acute abdominal emergency with early surgical intervention is essential if we are to save the patient's life. Careful observance of blood pressure and evidence of falling hemoglobin are serious warning signals, and adequate blood replacement is essential in the surgical treatment.

The maternal mortality rate has been high in the earlier cases reported but should markedly decrease with earlier surgery and adequate blood transfusion.

Conclusions

A ruptured splenic artery at the pedicle, probably associated with an aneurysm treated by early surgery and adequate blood replacement is essential for a successful outcome of this emergent situation. The outlook for the fetus remains grave due to the period of anoxia that invariably will occur as the result of hypotension. Awareness of the fact that acute surgical emergencies can occur in late pregnancies not associated with the pregnancy itself will contribute greatly to the successful outcome in the treatment of these cases.

WHAT'S YOUR DIAGNOSIS?

A 29-year-old right-handed man was in excellent health until four weeks prior to hospitalization when stiff neck and occipital headache developed. These symptoms would be present for two to three hours, would subside, and would recur approximately three times a week. Two weeks later unsteadiness in walking developed with a tendency to fall to the right. One week prior to his hospitalization nausea and vomiting developed.

On his admission to the hospital, his temperature was 100.2° F., blood pressure 128/80 mm. of mercury, and pulse 72 and regular. No abnormality of the cranial nerves was found except for bilateral early papilledema. There was no nystagmus. He did not have a stiff neck. He had generalized hyperreflexia, but the toes turned down on plantar stimulation. Results of the finger-nose and heel-knee tests showed evidence of moderately severe cerebellar ataxia on the right and a minimal amount of cerebellar ataxia on the left. There was some hypotonia on the right.

The hemoglobin measured 14.7 gm.; leukocytes numbered 6500 with a normal differential cell count. Roentgenograms of the cervical portion of the spinal column and of the head did not show evidence of any abnormality. An electroencephalogram showed delta waves, grade 1 biparietal occipital, maximal on the left, and generalized dysrhythmia, grade 2. Special contrast studies were then performed by a neurosurgeon.

Requisites

Medical Practice is not knitting and weaving and the labor of the hands, but it must be inspired with soul and be filled with understanding and equipped with the gift of keen observation; these, together with accurate scientific knowledge, are the indispensable requisites for proficient medical practice. — Maimonides (1135-1204)

Drive Safely

If you want to live to see ninety, don't keep looking for it on the speedometer.

Home Remedies of the Frontier*

During the larger part of the early life of Minnesota as a territory and a state, those on the frontier made their own medicine. There were no doctors or pharmacists nearby. People who were sick relied upon their own strong constitutions and the medicines that they could make from the materials around about them.

* * *

The Indians knew much about the curative properties of many growing things.

The Chippewas learned that the pitch of the balsam fir would help a headache. The umbrella plant was applied as a poultice for a sprain, and wild sarsaparilla was good for the blood. When a Chippewa chief had trouble with his eyes he sent the squaw out for the jack-in-the-pulpit and dogwood. Wild ginger was good for a pain in the stomach and the fern helped relieve bites, of which there were many.

The moccasin flower, later to become Minnesota's state flower, had something about it that would help a toothache. Fireweed was good for bruises and goldenrod was excellent for pain in the Redman's chest. Tamarack was used for burns and white spruce gum would help loosen a stiff joint. The plum had some disinfecting qualities and the blackberry helped a cough.

* * *

The frontier of the white man also had its remedies, some of which may have been learned from the Indians. Others had been handed down from generation unto generation and many of the things used in the earliest days in New England were found helpful, generations later, on the Minnesota homesteads.

Ginger, which the Indians found good for an inside pain, was a favorite remedy in the frontier home. Plenty of good red pepper with hot water was considered excellent for almost anything. Sweet flag, from the edge of a nearby swamp, was a good astringent. Pennyroyal was a standby. Sulphur and molasses made an effective, but not well liked, remedy for many ills.

The responsibility of making up the home remedies was usually left to some older member of the family, a grandmother if there was one around. When she noticed the peaked look and the spring lagging in the children she might put together a combination of yellow dock, black alder, burdock root, sassafras bark and wintergreen. This would be stewed on the back of the stove to make a drink which tasted bad enough to cure anything.

* * *

Anyone with any kind of ailment could get hope out of the early day newspaper. There was no lack of enthusiasm in the claims for what a bottle or a pill would do.

In the first issue of Minnesota's first newspaper, more than three columns of space were given to drug and medical advertising. Especially prominent were the claims for the goodness of Sloan's preparations for both man and beast. Not only did Sloan have a liniment for horses but he had an application for human beings that was especially effective for sprains, bruises, cuts, burns, chilblains, ulcers, pain-in-the-back and rattlesnake bites. Coxe's Hive Syrup, Stoughton's Bitters, and Thompson's Eye Water were evidently current favorites.

Computer Medicine

Its Application Today and Tomorrow*

MORRIS F. COLLEN, M.D.**
Oakland, California

THE ADVENT OF automation and computers will undoubtedly introduce a new era of medical practice. It is predictable that the computer probably will have the greatest technological impact on medical science since the invention of the microscope. The combination of automation and computers is already producing complex systems with speed and precision unmatched by even the most highly trained personnel: systems which can tirelessly perform routine repetitive procedures day after day, faster, more accurately, and in a manner not humanly practical, nor even possible.

Cybernated† systems, those combining automated equipment with computers utilizing on-line communications, are already being applied in the practice of medicine. The introduction of a cybernated system not only speeds up the quantity of work, improves the quality and lowers the cost, but usually produces changes in thinking and philosophy relative to the functional aspects of the work. For example, the introduction of a large automated chemical analyzer system coupled with electronic data processing has not only permitted us to perform laboratory tests faster, more accurately, and at a lower unit cost, but suggested that perhaps a broad profile of laboratory tests might be beneficially provided routinely to all patients, rather than the traditional teaching and practice of ordering only a limited number of tests for specific clinical indications. The advent of cybernated systems will permit mass production of more data on more people and also more data on each individual person. This will make feasible more explicit evaluation of medical care and also more accurate appraisal of one's biophysico-chemical individuality. One can reasonably predict that within ten years every hospital will have or will be participating in some cybernated systems.

---

*The research activities of this project are supported in part by grants from the Chronic Disease Division of the U. S. Public Health Service, and from the Kaiser Foundation Research Institute.

Paper presented at the 113th Annual Meeting of the Minnesota Medical Association, Saint Paul, Minnesota, May 16, 1966.

**Director, Medical Methods Research, The Permanente Medical Group.

†See Test Your Word Score Page 1719.

An example of a cybernated system in operation today in an outpatient department is that being provided in the San Francisco Bay Area to members of the Kaiser Foundation Health Plan. This Multiphasic Health Checkup, as it is called, is now being received by 40,000 adults each year. The entire Checkup consists of three parts: (1) the Automated Multiphasic Screening Program (a battery of tests and procedures); (2) a physical examination by an internist; and (3) a group of specialty physician examinations, including a gynecological examination (with cervical smear for cancer detection) and a sigmoidoscopy.

Automated Screening Program

The testing period of the Automated Multiphasic Screening Program takes two to three hours and includes the following:

1. Electrocardiogram (6 leads) simultaneously graphed on paper by a direct recording, multiple channel Sanborn optical oscillograph.
2. Chest x-ray (70 mm. minifilm).
3. Breast x-ray (cephalocaudal and lateral views in women over age 45).
4. Weight and skinfolds; height and other body measurements recorded by an automated anthropometer with direct punched card output.
5. Pulse and blood pressure recorded supine.
6. Visual acuity (modified Sloan chart) and pupillary escape test (an unsustained pupillary light reflex occurring in retinal or optic nerve disease).
7. Ocular tension (measured by Schiotz tonometer).
8. Retinal photograph (of right eye).
9. Forced expiratory vital capacity (1 sec., 2 sec. and total) and peak flow by the Wedge spirometer.
10. Pain reaction test (a modified Libman test measured as pain tolerance to increasing pressure on Achilles tendon).
11. Hearing test (for six frequencies by a Rudmose-Bekesy automated audiometer).
12. Self-administered health questionnaire forms (present and past history). In addition, a set of 207 medical questions on prepunched cards are sorted by the patient so that the "yes" responses can be automatically reproduced for computer processing.
13. Psychological questionnaire test with 155 questions sorted by the patient in a manner identical to (12) above.
14. Tetanus toxoid immunization (with Hypospray gun).
15. Blood chemistries performed within 12 minutes by a multichannel technicon AutoAnalyzer with direct punch card output, including: (a) Serum glucose (one hour after 75 gm. glucose orally), (b) Serum creatinine, (c) Serum albumin, (d) Serum total protein, (e) Serum cholesterol, (f) Serum uric acid, (g) Serum calcium, (h) Serum transaminase (SGOT).
16. Blood hemoglobin and white cell count automatically measured.
17. Blood group (ABO).
18. Serological (VDRL) test for syphilis.
19. Blood rheumatoid factor (latex fixation slide test).
20. Urinalysis for: (a) Urine pH, glucose, protein, and blood (paper strip) tests. (b) Urine bacteria (six-hour triphenyltetrazolium chloride culture of midstream specimen).
21. Automated multiphasic screening is completed and, in accordance with programmed "advice" rules, additional tests are arranged by means of an IBM 1440 computer, including return appointments for physicians. A summary report printout is provided to the physician before the time of his appointment with the patient. If the patient has certain combinations of symptoms and test values which fulfill the criteria for selected diagnostic categories, it is suggested that the physician consider these diagnoses.
23. The physician reviews the summary report at the time of the patient's office visits, directs further history toward elaborating upon the questions to which the patient has answered "yes," and to the reported test abnormalities. He completes his physical ex-

amination and communicates back to the computer by recording his findings and the patient's final diagnoses on a form which is processed through an optical reader and stored in the computer.

The Future

In the next five years it is likely that:

1. The electrocardiogram, the phonocardiogram, the blood pressure, and the respirogram will all be automatically read "on-line" by the computer.

2. Considerable progress will be made in the machine interpretation of roentgenograms.

3. Self-administered programmed questionnaires communicating directly with the computer will permit extensive history taking, utilizing "branching" questions. For example, if the patient answers "yes" to a general question, then the next question will branch into more detailed exploration of specific sub-systems.

4. Automated laboratory equipment will permit simultaneous analyses of 40 or more tests with continual "on-line" quality control monitoring by the computer.

5. Most data will be subjected to extensive processing and analyses before being presented to the physician to save his time. The computer will suggest to the physician likely diagnoses to be considered, with estimates as to the probable accuracy of these diagnoses as expressed in terms of sensitivity and specificity. As the complexity of the information increases and we supply more complex analyses, indices and profiles on patients, it will require more physician judgment, not less, to make optimal decisions how best to utilize the information for advice and treatment in accordance with the behavior and personality of the individual patient.

Conclusions

The physician who is skilled in diagnostic evaluation of the complex physiological systems of the human body is probably the best-trained systems analyst in present society. Once cybernated systems applicable to medical science become generally available, the practicing physician will not only readily accept and adjust to them, but will soon demand these services for his patients. In the future, it is likely that every community of 100,000 or more will have affiliated with one of its larger hospitals an automated multitest laboratory, which will be available for admission examinations and preoperative examinations for the hospital patients, and which will be utilized for office patients for periodic health examinations, general health examinations for special purposes (industrial, insurance, etc.), early sickness consultations and diagnostic surveys. These multitest laboratories will undoubtedly be affiliated with a regional computer center which will provide data processing services through connecting telephone lines.

ANSWER TO WHAT'S YOUR DIAGNOSIS

(From page 1703)

Ventriculography showed dilation of the entire ventricular system down to the middle of the aqueduct, which was displaced upward and forward by a mass in the posterior fossa.

Suboccipital craniectomy was performed. When the dura was opened the cerebellar tonsils were found to be herniated through the foramen magnum, on the right more so than on the left. A large cystic hemangioendothelioma was found in the right cerebellar lobe.

Photographic Contest

The Editors of MINNESOTA MEDICINE, in collaboration with the Doctors' Photographic Society of Minneapolis, take pleasure in announcing a monthly photographic contest. The contest is to promote an interest in photography in the medical profession. First prize each month will be publication in full color of the winning picture in MINNESOTA MEDICINE.

The following rules will govern the conduct of the contest:

1. Only doctors of medicine are eligible to submit pictures, and the picture must have been taken or composed by a physician.
2. Each contestant may submit not more than two pictures each month.
3. Only color transparencies, 35 mm. to 2¼″, can be considered.
4. Each slide should be labeled with the maker's name, address, and the identifying title.
5. Slides should not be mounted on glass, but can be protected in plastic sleeves or envelopes.
6. Each entry must be accompanied by a self-addressed, stamped envelope if return of the picture is desired. Returns will be made shortly after the close of the contest each month. The winning photograph will be retained but will be returned after it has been used.
7. The deadline date for entry will be the 10th of each month and the winner of each month's contest will be announced in MINNESOTA MEDICINE in the subsequent issue. The date of publication will be three to six months in advance.
8. There will be no limitation on subject material except as indicated in item 10.
9. Model releases will be requested of winners where appropriate.
10. Judges will be selected by the editors of MINNESOTA MEDICINE and the Doctors' Photographic Society. The judges will be guided by the precepts of the Photographic Society of America, and winners will be based on appropriateness, interest, impact, and technical excellence.
11. The editors of MINNESOTA MEDICINE and the Doctors' Photographic Society cannot be responsible for entries lost or damaged, but every effort will be made to protect submitted pictures.

Your pictures are hereby invited. Please submit pictures to:

Estimation of the Rate of Cholesterol Synthesis in Patients

IN RECENT YEARS there has been considerable interest in determining the effect of various cholesterol-lowering methods on cholesterol synthesis. In some instances, estimates of "synthesis rates" with a given regimen have been contradictory. For instance, in the case of large doses of nicotinic acid, studies in animals have indicated an increase,[1] a decrease,[2] and no change[3] in the rate of cholesterol synthesis. Such discrepancies have led to questions about the precision of the methods used in quantitating cholesterol synthesis.

Most workers in this field have used radioisotopes in their studies. The nature of radioisotopes requires the use of a number of basic assumptions in the calculation of synthesis rates from the data obtained. In making these assumptions the investigator must recall that assumptions which are true in the normal experimental animal or in patients may not be true in the presence of pathologic states or under the influence of drug therapy.

In attempts to estimate cholesterol synthesis in patients, two general approaches have been used. In the first method the patient is given a labeled precursor, such as ^{14}C-acetate, and the accumulation of labeled cholesterol in the plasma is measured. In the second method radioisotopes are not used but rather a balance study is carried out in which the dietary intake of sterol is known and the total excretion of cholesterol metabolites in the stool as bile acids and fecal sterols is accurately measured. The amount excreted in excess of dietary intake (on a mole for mole basis) represents synthesis. With the isotope method, changes in a number of factors other than cholesterol synthesis may affect the amount of radioactive cholesterol found in the plasma. These include dilution of the labeled precursor prior to its incorporation into labeled cholesterol; diversion of precursor to other metabolic pathways (such as into the synthesis of fatty acids); direct catabolism of the precursor to carbon dioxide; dilution of the labeled, newly synthesized cholesterol in the plasma by unlabeled cholesterol from other body pools (red blood cells, muscle, intestine, liver, skin, adrenals, and the nervous system); preferential movement of newly synthesized cholesterol into the plasma, the rate of cholesterol excretion as bile acids and fecal sterols, and changes in plasma volume. Changes in the rate of any of these processes would affect the percentage of the administered labeled precursor which appears in the plasma cholesterol fraction. If acetate is used as a precursor, less than 1% of the administered label appears as labeled cholesterol in the plasma. Thus it is evident that even small

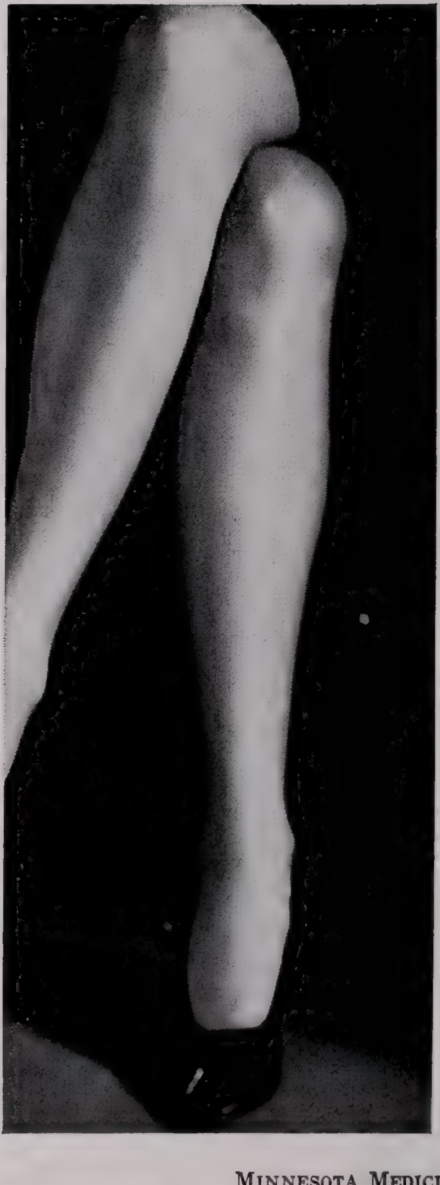
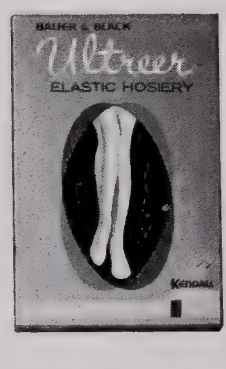
charm her with Ultreer™



You see, a woman simply has no defense against Ultreer Elastic Stockings. They look like lovely support stockings. They feel like lovely support stockings. They're that sheer, and shapely and comfortable.

But that's where the similarities end. New Ultreer fits firmly and evenly over the entire leg. Gives true therapeutic compression necessary to relieve varicose veins and other leg disorders. Each pair provides the therapy you prescribe. And at such a low price, a woman can afford two pairs of Ultreer as easily as she can afford one pair of ordinary elastic hosiery.

Ultreer. What a stocking.



KENDALL
BAUER & BLACK SUPPORTS DIVISION

changes in these other factors could have a profound effect.

These problems are complicated further by the fact that cholesterol is not uniformly distributed throughout the body, and the rates of exchange of cholesterol between the various body pools may vary from less than two hours, in the case of the liver, to at least a month and probably longer in the case of nervous tissue. Although information regarding the controlling factors in cholesterol synthesis is limited, available information from animal studies indicates that *liver* synthesis can be inhibited by dietary cholesterol, whereas neither *intestinal* synthesis nor *skin* synthesis is affected.[4] Recent studies [5,6] suggest that bile acids may inhibit *intestinal* cholesterol synthesis. Equilibration of intestinal cholesterol with the plasma pool is via the lymphatics, a slow system in comparison to the rapid exchange between the liver and plasma.

In their report, *Human Serum Cholesterol Synthesis,* Taylor and associates* have overcome the problem of changes in the rate of cholesterol excretion by measuring the degree of labeling of cholesterol rather than the total amount of label in the cholesterol fraction. Also, problems of dilution and preferential pool shifts of the newly synthesized cholesterol are minimized by the prolonged (40 to 50 days) period over which the precursor was given. The massive dose of the label given reduces the likelihood that diversion of the precursor to other pathways is a limiting factor. The authors' correction for the dilution of deuterocholesterol by exogenous dietary cholesterol, however, may not be valid. In their calculation, they assumed that the increase in concentrations of serum cholesterol which occurred when the subjects were changed from a cholesterol-free to a cholesterol-rich diet was merely a reflection of an increase in the size of the cholesterol pool. They did not take into account the possibilities that changes in rates of cholesterol synthesis, excretion, or distribution to other body pools may have affected the concentration of serum cholesterol. Studies by others have suggested that cholesterol synthesis by the liver is affected by cholesterol feeding.

In order to obtain the half-life of deuterocholesterol and from this to calculate its turnover and daily synthesis rate, Taylor and associates plotted their data on semilog paper after the manner of London and Rittenberg.[7] To obtain a meaningful half-life value from which a synthesis rate can be derived, this plot must be linear. While no such plot is included in this article, several are illustrated in a more detailed report of this study. These plots do not appear to be linear.[8] Therefore, while this method overcomes some of the problems, others remain.

The second method for measuring cholesterol synthesis, the balance study, also has its problems. The accurate quantitation of fecal bile acids and sterols is a difficult chemical procedure. Recently, a group at Rockefeller Institute[9,10] has overcome this problem by using a combination of thin-layer, alumina column, and gas-liquid chromatography. The other major problem of a balance study involves the possibility of a change in the total body pool of cholesterol between the study periods. Thus, the precise quantitation of cholesterol synthesis in human beings is fraught with many possible errors.

Finally, I feel that the conclusions expressed by Taylor and associates in their report need amplification. In their studies they attempted to measure *total* cholesterol synthesis in patients and were unable to demonstrate a feedback mechanism for compensating for dietary cholesterol in man. In contrast, workers proposing a feedback mechanism in rats and dogs[4,11] pointed out in their studies that this mechanism is in operation in the liver but not in the skin and intestine. Many investigators feel that the skin and intestine may be as important as the liver in total cholesterol synthesis.

P·B·SAL·C
NON-HORMONAL ANTI-ARTHRITIC

Helps keep arthritic patients active

P-B-SAL-C is a dependable, effective salicylate formula for relief of pain due to rheumatoid arthritis, bursitis and fibrositis.

Its formula consists of a combination of sodium salicylate, para-aminobenzoic acid and ascorbic acid. This special combination provides higher, longer-lasting analgesic levels compared with salicylates alone. Each P-B-SAL-C Tablet is enteric coated to delay disintegration until it reaches the small intestine.

P-B-SAL-C, low in cost to your arthritic patients, will help keep them active. Other P-B-SAL-C formulas available:
1. P-B-SAL-C with Colchicine
2. P-B-SAL-C with Esoprine
3. P-B-SAL-C Sodium Free
4. P-B-SAL-C with Prednisolone (Sodium Free)

For complete information and samples, write to Dept. MM-100

FORMULA

Each enteric-coated P-B-SAL-C Tablet contains sodium salicylate 0.3 Gm., para-aminobenzoic acid 0.3 Gm., ascorbic acid 50.0 mg.

CONTRAINDICATIONS

Renal damage, salicylate sensitivity or in conjunction with sulfonamide therapy.

DOSAGE

Take 2 tablets four or more times daily.

Minneapolis, Minnesota 55403

Quantitative Urine Cultures*

THE CURRENT concept of enumerating microorganisms in urine as an aid in establishing a diagnosis of urinary tract infection is receiving a great deal of attention. Quantitation has merit only if careful attention is given to factors controlling the outcome of attempts to determine the number of bacteria in bladder urine.

The procedure employed in collecting a specimen for bacteriologic examination is one of the most important steps in establishing a bacteriologic diagnosis. Material to be examined bacteriologically often contains microorganisms representative of the normal or usual flora of the region. For example, sputum and feces contain many types of bacteria; and it is the responsibility of the bacteriologist to separate the usual or normal inhabitants from potential pathogens. It is virtually impossible to collect any specimen, even of blood or spinal fluid, and be absolutely assured that it will be free of an occasional contaminant. For this reason any culture procedure should provide some method of quantitating the organisms present. Unless this criterion is met, the true significance of the mere presence of organisms may not be clear.

Urine obtained by any procedure, and especially by the clean-catch method, may contain a few bacteria. Prompt transportation to the laboratory is essential, since urine may serve as a culture medium for certain bacteria. Low counts may increase to a significant level in a relatively short time; and, conversely, high counts may be reduced if there are antibacterial agents in the urine.

What constitutes a significant number of bacteria in the urine is a question for which a universally acceptable answer is still lacking. Various techniques have been described for estimating bacterial populations, none of which approach the accuracy attainable with cultures prepared by inoculating suitable media with an inoculum from a standard loop or an appropriate tube dilution of the urine.

Since obtaining urine completely free of bacteria is extremely difficult, aside from suprapubic aspiration, caution must be exercised before establishing a definitive bacteriologic diagnosis. If meticulous attention is paid to collection and transportation, if reliable quantitative bacteriologic procedures are used, and if critical evaluation of the bacterial population is made by one experienced in medical bacteriology, then quantitative urine cultures do provide clinicians with specific and accurate information.

Hypercalcemic Crisis*

THE CLINICAL manifestations of hypercalcemia may be quite variable and may affect any body system. An awareness of the more common ones is essential to the clinician, if serious, even fatal, consequences of marked hypercalcemia are to be avoided.

Minimal hypercalcemia may be asymptomatic but is often associated with renal stones, duodenal ulcer, or pancreatitis. Higher levels of serum calcium may also be associated with these disorders, but other gastrointestinal, muscular, central nervous, and cardiovascular symptoms may predominate. Hypercalcemia should be suspected in patients with unexplained anorexia, weight loss, nausea and vomiting, severe constipa-

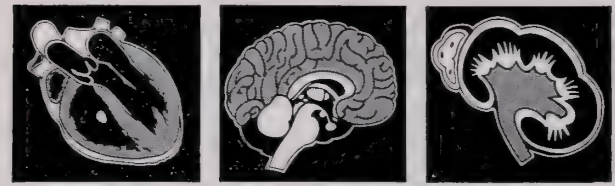
SQUIBB NOTES ON THERAPY

Behind continued high blood pressure readings lies the possibility of organic damage[1-13]

MANY OF THE aspects of essential hypertension are unpredictable—either because there are a number of mechanisms involved or because individuals differ in their responses to these mechanisms.[1]

There is one aspect of hypertension, however, that seems, in many cases, predictable. ". . . when the blood pressure is elevated to a marked degree for an adequate period of time, this in itself leads to perpetuation of the syndrome with resulting vascular damage throughout the body."[14] All too often the disease progresses until there is damage to one of three vital organs: the heart, the kidney, the brain.



> "Hypertension is certainly a major factor in the genesis of coronary heart disease, and it is even more important when compounded with obesity."[4]
>
> "[Vascular deterioration] can be clearly seen in the kidney with a degree of damage that can be measured by renal function studies."[10]

". . . most evidence suggests that reduction of blood pressure, when it is too high, not only relieves the heart of excess work but reduces vascular damage."[1]

"In short, treatment is indicated."[1]

Antihypertensive therapy will not restore the blood vessels to normal. Yet many of the vascular changes and symptoms caused by increased blood pressure may be arrested or alleviated when the blood pressure is reduced to normotensive levels.[7]

Reducing the blood pressure helps curtail further vascular damage and improves the prognosis — when damage is not too far advanced before therapy is started.[14] Essential hypertension is an indication not only for treatment, but for *early* and adequate treatment of the patient in question.

Reduce the blood pressure with Rautrax-N

Rautrax-N combines the antihypertensive-tranquilizing action of whole root rauwolfia with the antihypertensive-diuretic action of bendroflumethiazide in one convenient medication. The two drugs complement each other so that smaller doses of both are possible.

Rauwolfia combined with bendroflumethiazide is particularly effective in long-term therapy,[15-17] since beneficial effects do not diminish with continuous daily administration.

For most patients 1 or 2 Rautrax-N tablets daily are sufficient for maintenance therapy. The simplicity, convenience and economy of such a dosage schedule are of particular benefit to older patients.

Contraindications: Severe renal impairment or previous hypersensitivity. **Warning:** Ulcerative small bowel lesions have occurred with potassium-containing thiazide preparations or with enteric-coated potassium salts supplementally. Stop medication if abdominal pain, distension, nausea, vomiting or G.I. bleeding occur.

Precautions and Side Effects: The dose of ganglionic blocking agents, veratrum or hydralazine when used concomitantly must be reduced by at least 50% to avoid orthostatic hypotension. Caution is indicated in patients with depression, suicidal tendencies, peptic ulcer; electrolyte disturbances are possible in cirrhotic or digitalized patients. Marked hypotension during surgery is possible; consider discontinuing two weeks prior to elective surgery and observe patients closely during emergency surgery. Rauwolfia preparations may cause reversible extrapyramidal symptoms and emotional depression, diarrhea, weight gain, edema, drowsiness may occur. Bendroflumethiazide may cause increases in serum uric acid, unmask diabetes, increase glycemia and glycosuria in diabetic patients, and may cause hypochloremic alkalosis, hypokalemia; cramps, pruritus, paresthesias, rashes may occur.

Dosage and Supply: Initial dosage, 1 to 4 tablets daily, preferably at mealtime. Maintenance, 1 or 2 tablets daily. Rautrax-N is supplied as capsule-shaped tablets containing 50 mg. Rauwolfia serpentina whole root (Raudixin®), 4 mg. bendroflumethiazide (Naturetin®), 400 mg. potassium chloride.

Also available: Rautrax-N Modified — capsule-shaped tablets containing 50 mg. Rauwolfia serpentina whole root (Raudixin), 2 mg. bendroflumethiazide (Naturetin), 400 mg. potassium chloride. Both potencies available in bottles of 100. For full information, see Product Brief.

tion, generalized muscular weakness, altered states of awareness or consciousness, thirst, or increased urination.

Serum calcium should be determined in any patient when these symptoms cannot readily be ascribed to known associated disorders. This examination should be a part of the initial medical evaluation, since marked hypercalcemia is a medical emergency and requires prompt recognition and treatment. Death may occur during severe hypercalcemia and is usually attributed to effects on the heart.

Hypercalcemic crisis may appear in primary hyperparathyroidism, malignancy (with or without bony metastasis), vitamin D intoxication, multiple myeloma, milk-alkali syndrome, or sarcoidosis. Sufficiently elevated levels of serum calcium to reach crisis proportions could develop in many states of moderate hypercalcemia if dehydration occurs.

Hypercalcemia due to primary hyperparathyroidism is best treated by surgical exploration and removal of the abnormal parathyroid tissue, usually a single adenoma. Effective, safe, and prompt medical treatment for other hypercalcemic disorders is less satisfactory.

Correction of dehydration is of primary importance, and ancillary measures, such as the use of large doses of corticosteroids or intravenous disodium ethylene-diaminetetraacetate (EDTA), often are required. Corticosteroids have the disadvantage of a lag period that may last several days before an effective response occurs. An appreciable number of patients with hypercalcemia due to malignancy do not respond to corticosteroids with a reduction in serum calcium. Large doses of corticosteroids may be contraindicated in certain patients for other medical reasons.

EDTA infused intravenously often decreases serum-calcium levels by its chelating action, but this effect usually persists for only a short time after infusion is discontinued. Repeated administration invokes the appreciable hazard of renal damage.

Goldsmith and Ingbar[1] have used buffered phosphate solutions orally or intravenously in the management of hypercalcemia of divergent causes with good results. The potential complication of extraskeletal calcification has not been a problem in their cases. The mechanism by which reduction in serum calcium occurs is not known, but the effect is prompt; therefore this appears to be an approach to the treatment of severe hypercalcemia that merits further investigation.

Acute Myelocytic (Granulocytic) Leukemia: Current Therapy*

VINCRISTINE AND prednisone produce a complete hematologic remission in as many as 90% of patients with acute lymphocytic leukemia, and this remission can be maintained with intermittently administered oral methotrexate for more than a year.[1] Unfortunately, treatment of acute myelocytic leukemia is much less satisfactory. In fact, 6-mercaptopurine, the current standard treatment of choice, produces a complete remission in less than 10% of patients.[2] Of all cases of acute leukemia in adults, 80% are of acute myelocytic leukemia. My colleagues and I include myelomonocytic leukemia (Naegeli) in the myelocytic leukemia group since the responses of both conditions to therapy are the same.

Because infection and hemorrhage are the two most common causes of death in acute leukemia, supportive therapy is extremely important. Fever may occur from the leukemic process itself, but in the majority of

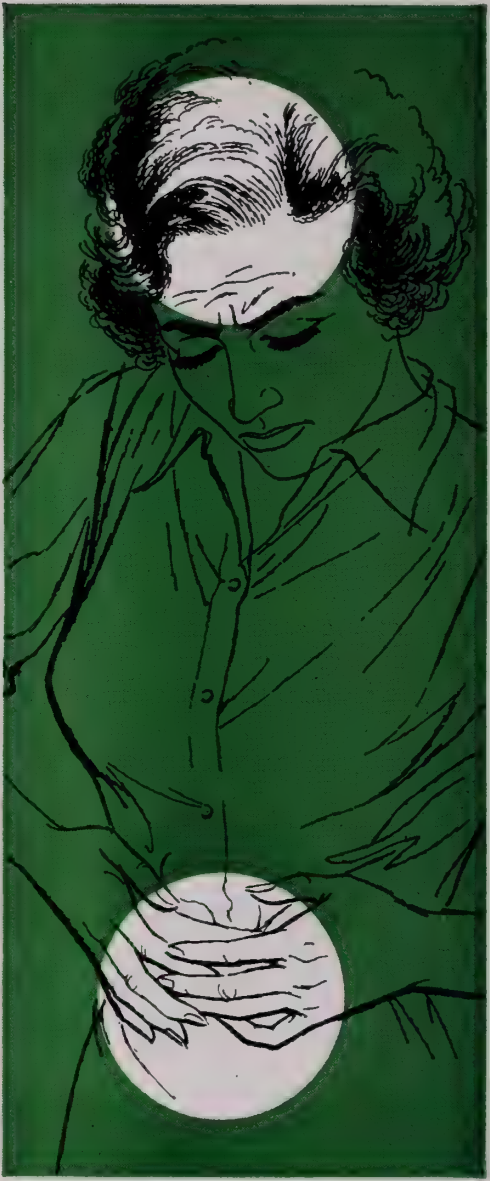
WARNING: MAY BE HABIT FORMING
BELLADONNA EXTRACT (TOTAL ALKALOIDS 0.188 MG.), 15 MG.

provides gentle,

intermediate sedation and

relaxes 'G. I.' spasm.



Butadonna quiets the "brain-on-gut" influences by providing the smooth, intermediate sedative, butabarbital sodium, desirable in combination with the proven antispasmodic, belladonna extract. Butabarbital sodium is more rapidly eliminated than phenobarbital, and avoids the latter's cumulative effect.

Indications: Antispasmodic-sedative. Useful in the treatment of peptic ulcer, gastritis, duodenitis, irritable colon syndrome, ulcerative colitis, regional enteritis, and other conditions associated with gastrointestinal spasm. Also may be useful in functional dysmenorrhea.

Usual adult dosage is one tablet 3 or 4 times daily as needed.

Caution: Contraindicated in glaucoma and urinary retention. Reduce dosage or discontinue use in event of blurring of vision, dryness of mouth, tachycardia, or excessive drowsiness. Continued use of butabarbital sodium may be habit forming.

Cole

COLE PHARMACAL COMPANY, INC.

instances it results from infection. Patients with acute leukemia are overly susceptible to infections and tolerate them poorly. Examination of the patient and cultures of blood, sputa, and urine as well as chest roentgenograms and prompt institution of appropriate antibiotics are necessary. My colleagues and I do not believe that the use of prophylactic antibiotics is indicated in these cases. If available, granulocyte transfusions may be helpful for the patient with neutropenia. Infusion of fresh blood or platelet-rich plasma may be lifesaving in the event of severe bleeding from thrombocytopenia.

Oral ulceration may prove very troublesome and can be alleviated with the use of viscous xylocaine before meals. A protective-emollient preparation (Orabase) can be used to cover an ulcerated lesion. Mouthwashes with hydrogen peroxide also decrease local oral discomfort. Nystatin (Mycostatin) or gentian violet is usually very beneficial in the treatment of oral moniliasis.

Radiation is generally contraindicated in acute leukemia, but very small doses have been helpful in instances of localized bone pain, ulceration, or chloroma.*

Since orally-administered 6-mercaptopurine is ineffective for the majority of patients with acute myelocytic leukemia, much effort has been made to devise new therapy. The combination of 6-mercaptopurine and cyclophosphamide as described in this issue produced a constant decrease in leukocytes and myeloblasts; but bone-marrow remissions were documented in only two cases. This particular mode of therapy cannot be recommended at present. However, the increase in hemoglobin concentration and platelet count is of interest, and future studies with these therapeutic agents may be fruitful.

The use of corticosteroids in acute myelocytic leukemia is controversial. Despite other opinions, my colleagues and I consider that prednisone is not contraindicated and that, after 6-mercaptopurine failure or in the event of significant bleeding, an initial dose of 100 to 150 mg. of prednisone daily can be given, along with antacids and a bland diet in order to decrease the possibility of peptic ulceration.

We have used methylglyoxyl-bis-guanylhydrazone dihydrochloride (methyl-GAG), an investigational drug effective against L 1210 mouse leukemia, in human beings. Despite earlier optimistic reports, our recent studies record a rate of remission of no more than 25%. Intravenous administration of the drug produces considerable gastrointestinal toxicity, but intramuscular injections are less toxic. In our experience, methyl-GAG and hydroxystilbamidine have not been helpful despite initial encouraging experience in animals. Methyl-GAG combined with 6-mercaptopurine was reported to have resulted in remission in one third of 42 patients with acute myeloblastic leukemia.[3]

A combination of vincristine, methotrexate, 6-mercaptopurine, and prednisone in large doses has been used, with some increase in remission rate, but unfortunately, this large dose schedule is very toxic. Recently, Thompson and associates[4] have reported encouraging results, after utilizing smaller doses of these four drugs. Further studies are needed.

Cytosine arabinoside, given intravenously, has produced complete bone-marrow remission in 12 of 77 patients with acute myelocytic leukemia.[5] This drug requires further evaluation.

Treatment of acute myelocytic leukemia has been discouraging. The chemotherapeutic agent of choice at present remains 6-mercaptopurine. In all cases, supportive treatment at the same time is usually necessary.

Robert A. Kyle, M.D.
Rochester, Minnesota

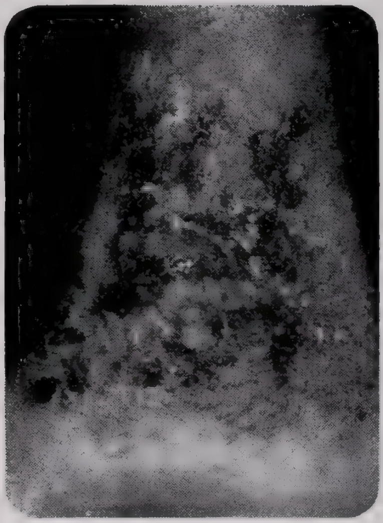
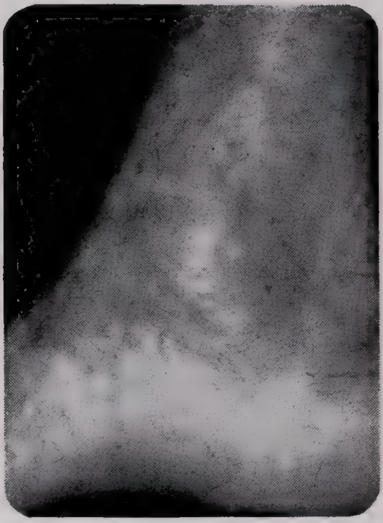
eczema: scourge of childhood



R. R., Age 11 — Before treatment — atopic eczema of long standing



After treatment — with ARISTOCORT Topical Ointment 0.1% for two weeks

ARISTOCORT® Triamcinolone Acetonide Topicals have proved exceptionally effective in the control of various forms of childhood eczema: allergic, atopic, nummular, psoriatic, and mycotic.

In most cases responsive to topical ARISTOCORT, the 0.1% concentration is sufficiently potent. The 0.5% concentration provides enhanced topical activity for patients requiring additional potency for proper relief.

Administration and Dosage: Apply sparingly to the affected area 3 or 4 times daily. Some cases of psoriasis may be more effectively treated if the 0.1% Cream or Ointment is applied under an occlusive dressing.

Contraindications: Tuberculosis of the skin, herpes simplex, chicken pox and vaccinia.

Precautions and Side Effects: Do not use in the eyes or in the ear (if drum is perforated). A few individuals react unfavorably under certain conditions. If side effects are encountered, the drug should be discontinued and appropriate measures taken. Use on infected areas should be attended with caution and observation, bearing in mind the potential spreading of infection and the advisability of discontinuing therapy and/or initiating antibacterial measures. Generalized dermatological conditions may require systemic corticosteroid therapy. Steroid therapy, although responsible for remissions of dermatoses, especially of allergic origin cannot be expected to prevent recurrence. The use over extensive body areas, with or without occlusive nonpermeable dressings, may result in systemic absorption. Appropriate precautions should be taken. When occlusive nonpermeable dressings are used, miliaria, folliculitis and pyodermas will sometimes develop. Localized atrophy and striae have been reported with the use of steroids by the occlusive technique. When occlusive nonpermeable dressings are used, the physician should be aware of the hazards of suffocation and flammability. The safety of use on pregnant patients has not been firmly established. Thus, do not use in large amounts or for long periods of time on pregnant patients.

Packages: Tubes of 5 Gm. and 15 Gm.; ½ lb. jar.

Surgery for the Carotid Artery

THE FINE ARTICLE by Garamella et al. published in this issue of Minnesota Medicine* attests to their technical proficiency in restoring flow in occluded carotid arteries. It is good also that the medical profession be exposed to a positive approach in this very common problem. However, in all fairness to our medical audience, it should be stressed that restoration of flow in totally occluded carotid arteries is not synonymous with restoration of function and, in fact, may cause a worsening of the patient's condition by way of hemorrhage to an area of ischemic brain.

Dr. Garamella mentions the vagaries of interpreting his data. The results in his patients wherein flow was successfully reestablished are better, but not markedly so, than in the patients where flow was not reestablished.

At the present time the best results are obtained when surgery is performed on those patients with intermittent symptoms who have had careful study of the carotid and vertebral system and in whom a partially occluded vessel is demonstrated. The question of whether surgery should be advised for the completed stroke patient remains a moot one. Hopefully, a carefully randomized study will, in the future, clarify the issue.

Importance of National Program for Aerospace Medicine

GENERAL NIESS* has pointed out lucidly the need for continued support of our national aerospace research program. Many persons are confused as to the purposes of the national program of research in aerospace medicine and have difficulty in understanding the purposes behind such a program. In particular, it is very difficult for the uninformed to understand how anything "practical" can be derived from space research. I think General Niess has clarified this question very well indeed.

General Niess also has set forth the prevailing philosophy of those engaged in aerospace medical research, and I am sure he has explained some of the thinking behind the work of a large number of biologists and other aeromedical scientists busily engaged in this very broad field of research.

Utilization of Thebesian Blood Flow in Treatment of Coronary Heart Disease

The heart musculature has a double blood supply. Seventy-eight percent of the blood supplying the heart muscle comes from the coronary artery, and 12 percent comes through by way of the thebesian vein.[1]

Prinzmetal[2] placed microscopic beads in the auricle and traced them into the coronary circulation.

Vineberg[3] and Lillehei[4] have demonstrated that they can save victims of coronary heart disease by inserting a bleeding artery or vein directly into the damaged musculature of the heart, thus giving the heart the opportunity to survive. Nature has supplied us at birth with these passages to deliver blood and oxygen to distressed heart muscles when in need. Several authors[5,6,7] have stated that the heart can be so trained by gradual adaptation to stress, if one can learn how to utilize the function of the thebesian venous system, thus providing a blood supply to the heart musculature by an ebb and flow process. Then it may be possible to prevent or delay complete heart failure.

The surgical method of providing blood to the heart by suturing a bleeding vessel into a prepared groove becomes possible because the heart muscle is sponge-like in its structure. Hence the reaction is similar to pouring into a sponge fluid which quickly disperses throughout, so that as the sponge is squeezed more fluid can be absorbed. Is it not possible that this is precisely what happens in systole and diastole when the spongy heart muscle[8] receives the blood from the thebesian vein and into the loose musculature of the ventricle, producing, in effect, a profusion of blood to nourish the injured ventricular muscular?

My first experience was obtained from the history of a man[8] who suffered from angina and, unable to find his nitroglycerine, gasped with delight as he heard the beautiful singing of a bird. As he did this his angina disappeared, and from that I developed the process of controlled deep breathing as a method of endeavoring to produce an ebb and flow type of blood perfusion through the thebesian vein.

By a process of controlled diaphragmatic breathing, every five minutes out of every two hours the patient is taught to utilize the ebb and flow of the arterial and venous blood to aid in perfusing the heart musculature.

By this method I have observed beneficial results in more than one hundred patients whom I have treated .

The alienist is not a joke; He finds you cracked, and leaves you broke. —
Keith Preston

Most of my patients with high blood pressure are as old as I am. A lot of them are living on pensions. They're grateful when I can keep prescription costs down.

Regroton®

chlorthalidone 50 mg. reserpine 0.25 mg.

1 tablet daily brings pressure down

Advantage: Both components of Regroton are long-acting.
Average dosage: One tablet daily with breakfast.
Contraindications: History of mental depression, hypersensitivity, and most cases of severe renal or hepatic diseases.
Warning: Discontinue 2 weeks before general anesthesia, 1 week before electroshock therapy, and if depression or peptic ulcer occurs. With administration of enteric-coated potassium supplements, the possibility of small bowel lesions should be kept in mind.
Precautions: Reduce dosage of concomitant antihypertensive agents by one-half. Discontinue if the BUN rises or liver dysfunction is aggravated. Electrolyte imbalance and potassium depletion may occur; take particular care in cirrhosis or severe ischemic heart disease, and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended. Use with caution in patients with ulcerative colitis, gallstones, or bronchial asthma.
Side effects: Nausea, vomiting, diarrhea, muscle cramps, headaches and dizziness. Potential side effects include angina pectoris, anxiety, depression, drowsiness, hyperglycemia, hyperuricemia, lassitude, leukopenia, nasal stuffiness, nightmare, purpura, urticaria, and weakness.
For full details, see the complete prescribing information.
Availability: Bottles of 100 and 1000 tablets.

Jaundice and Kernicterus

QUESTION: In which cases of jaundice in infants is kernicterus most likely to be damaging?

ANSWER: Jaundice is most likely to be damaging if a. jaundice is due to hemolytic disease of the newborn; b. the infant is premature, especially of less than 5 lbs; c. jaundice is associated with anoxia, free fatty acids in the serum (as in starvation), or sulfa drugs; d. jaundice is associated with low serum albumin.

There are varying degrees of kernicterus and follow-up in most studies is inadequate. For a good discussion of the problems surrounding "physiologic jaundice" in both premature and full-term infants see R. L. Day, Pediat Clin N Amer 8:539, 1961.

I believe the answer in the toxicity of indirect bilirubin in newborns is whether the infant has enough serum albumin to bind all its indirect bilirubin. We now have a simple lab test available to measure the serum albumin which is free to combine with additional indirect bilirubin and keep the bilirubin from going into the cells.*

The physician who knows both the indirect bilirubin level and the albumin-binding capacity should be able to prevent all cases of kernicterus without subjecting to exchange transfusion infants who don't really need it.

Vaginal Discharge

QUESTION: Does the wearing of high heels affect vaginal discharge?

ANSWER: Vaginal discharge is a common gynecological symptom. Patients may claim that discharge is related to special situations. There is no evidence to indicate that the wearing of high heels or any other kind of heel would or could actually cause or increase vaginal discharge. On the other hand, violent activity or jarring of the body may be associated with the escape of vaginal moisture. Normal moisture is present in all women. Sports like tennis, horseback riding, and walking with high heels may cause the material to descend to the introitus. One should inspect carefully the cervix of these patients. A cervicitis or excessive cervical secretion may be present. Douches and vaginal inserts are without value in correction of cervicitis or excessive cervical secretion.

Soyalac SOLVES THE PROBLEM

...and BABY APPROVES!

Baby has a thing or two to say about a hypo-allergenic, milk-free diet!

Soyalac is the good-tasting, fibre-free formula that infants readily accept. The exclusive Soyalac process results in a consistency much like milk, with a light, creamy color—and nut-like flavor but without a trace of sediment.

Soyalac satisfies the infant. Strikingly similar to mother's milk, it provides protein of high biologic value and balanced nutrients. Clinical data furnish evidence of Soyalac's excellence in promoting normal growth and development.

The Viewing Box

Lesions of the Pelvis

in a

59-Year-Old Woman

A 59-year-old woman complained of easy fatigability and back distress since a hysterectomy in 1956. The operation was followed by roentgen therapy to the pelvis. Five months prior to this 1966 study she developed left leg weakness and a mild left pelvic pain radiating to the thigh. This was relieved by Bufferin.

The x-ray (Figure 1) reveals a generalized extensive coarsening of the trabecular pattern and loss of normal mineralization interspersed with practically intact bone above the acetabular fossae bilaterally. There is an area over the superior aspect of the left iliac bone measuring 10 cm. in greatest diameter which reveals extensive dense mineralization and fairly sharp delineation. Throughout the pelvis no frank destruction is seen and there is no evidence of old or recent fracture.

What is your diagnosis? (See next page.)

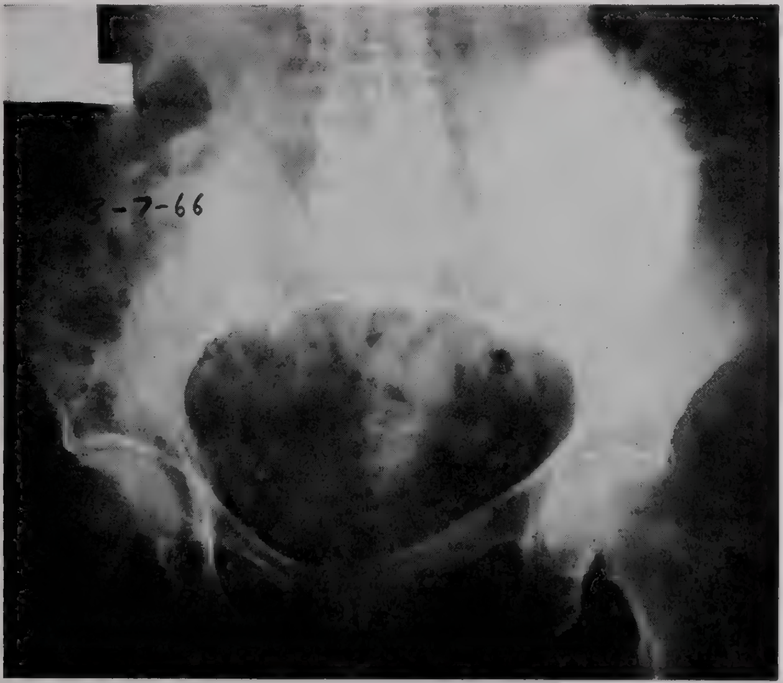

Figure 1

DIAGNOSIS: **Post Radiation Osteogenic Sarcoma**

The vulnerability of bone and cartilage to the effects of radiation are well known and were observed shortly after radiation was first utilized. Exclusive of multiple myeloma, osteogenic sarcoma is the most commonly encountered malignant primary bone tumor and also appears to be the most common of the radiation-induced sarcomas.[14]

Of almost 6,000 patients reported by Phillips and Sheline,[11] sarcomas developed in only two, giving an incidence of 0.3%, or 0.1% of the 2,300 five-year cancer survivals. Thus, although radiation induction of bone sarcoma does occur in normal bone, it is a rare complication of radiation therapy for malignant disease. The present case, for example, is the fourth reported case following external beam therapy for cancer of the cervix.[1,11,15]

The first convincing reports indicating that irradiation of bone may be followed by the development of sarcoma refer to those patients who were irradiated for tuberculous joints or chronic osteomyelitis.[15] Others[5,13] have emphasized this sequence after radiation therapy for benign bone tumors. The most spectacular example of bone sarcoma resulting from radiation has been found in dial painters who repeatedly ingested minute amounts of radium, mesothelium or radiothorium. Hatcher[8] also showed that radiation could cause sarcomas in healthy bone and that these may occur following treatment for dermatoses or malignancy.[13]

The ages of patients at the time of appearance of these iatrogenic sarcomas which have developed in normal bone or a benign bone lesion range from 4-68 years, averaging 37 years.[15] Spontaneous osteogenic sarcomas, however, develop in a younger age group insomuch as almost half occur from 10-19 years.[6]

The time from the last radiation to the onset of clinically determinable sarcomatous change is defined as the latent period.[4,6] It has ranged from 4-30 years, averaging 12, 8.6, 20 and 13.5 years in recent large series.[4,10,13,15]

The most prominent symptoms of malignant change are the rather sudden onset of constant and progressive pain and tenderness and the presence of a local mass.[12]

In general, patients have received rather large doses of low energy radiation; a threshold dose of 3,000 r. with repeated exposure has been reported.[10] However, secondary malignant bone tumors may develop after small doses in children.[5] Moreover, it has been established[7] that in most cases there is a factor of skin change and radiation damage to adjacent structures. Gonadal dysfunction, soft tissue damage, disturbed bone growth, radiation osteitis, avascular necrosis, sequestration and pathological fractures have been associated with this condition.[13]

Cahan et al.[4] defined the prerequisites of the condition (satisfied in this case):

1. There must have been microscopic or x-ray evidence of the nonmalignant nature of the initial bone condition.
2. Irradiation must have been given and the sarcoma that subsequently developed must have arisen in the area included within the radiotherapeutic beam.
3. A relatively long asymptomatic latent period must have elapsed

after irradiation before the clinical appearance of the bone sarcoma.

4. All sarcomas must have been proven histologically.

During the latent period changes occur which can be described as precancerous: they are progressive, almost always resulting in fibrosis, scarring and atrophy. The osteitis has been attributed to the finding that osteoblasts are more sensitive to irradiation than osteoclasts. Hence osteoporosis may be the result of a disturbance in the normal balance between resorption and production of bone.[9] Cruz et al.,[7] in noting the associated radiation osteitis of an extreme degree, have suggested that sarcomatous change occurs in bone which has suffered an intermediate damage. Raventos[12] feels, however, that the present evidence does not permit any conclusion as to whether the radiation-induced sarcoma most often arises in bone which has undergone radiation resorption or in areas of lesser damaged bones. Hatcher[8] suggested that bone rich in hematopoietic tissue or reticuloendothelial cells might be more prone to develop sarcoma than bones which have a greater proportion of fatty marrow. It has also been suggested that the predisposition of the individual to neoplastic growth is a factor in development of radiation sarcoma.

Though Cruz[7] reported two cases remaining free of disease following amputation, it is the experience of Steiner[15] that once a sarcoma has appeared in irradiated bone the possibility of survival is minimal even if the affected part is amputated promptly.

Radiation nephritis, pneumonitis, myelitis can be almost completely guarded against and iatrogenic carcinogenesis can be greatly reduced.[2] However, some sarcomas following irradiation will continue to occur. It is hoped that with greater utilization of supervoltage and less bone absorption of energy per roentgen the incidence of bone sarcoma will be reduced just as there has been a reduction of mandibular necrosis and

Continued

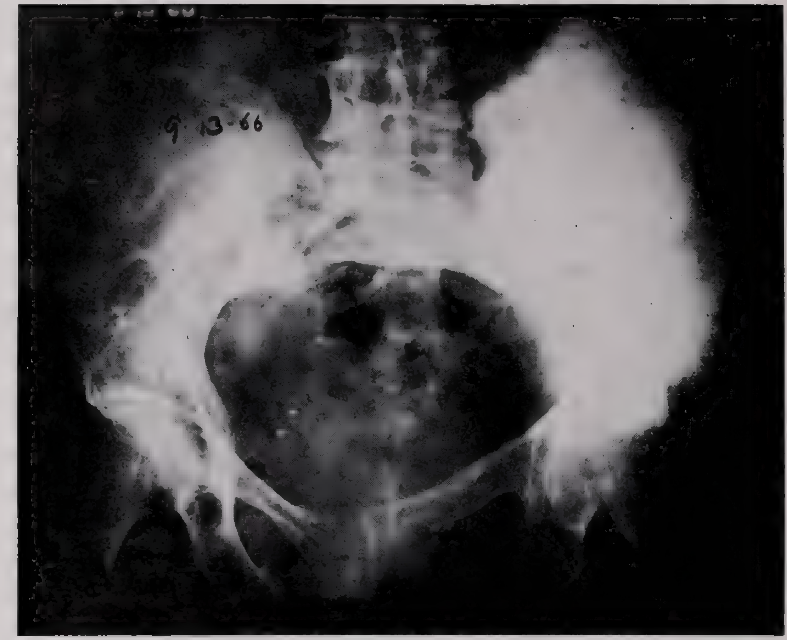

Figure 3

chondronecrosis of the laryngeal cartilage.[2]

It has been recommended[2,3,11] that benign lesions treatable by other means should not be treated with irradiation and that radiotherapy in children should be limited to the treatment of carcinoma.

In the case discussed the tumor arose in normal bone (Figure 2) which had been in the field of irradiation. Following a panhysterectomy in 1956, histological studies revealed an infiltrating anaplastic carcinoma of the cervix. Roentgen therapy was administered with the following technical factors: 200 kvp; thoraeus filter; 20 ma.; 50 cm. tsd. A daily exposure of 350 r. in air was given to one of five fields (anterior, right and left posterior, and right and left lateral). The fields, which measured 10 × 15 cm., extended from the iliac crest to the pubic level. Thirty treatments were given with a total exposure dose of 2,100 r. in air to each field in 33 days. Subsequently, the patient developed an acute dermal reaction which was followed by severe scarring and telangiectasia.

The radiograph (Figure 1, previous page) has demonstrated a generalized radiation osteitis and an osteogenic sarcoma of the left iliac bone, confirmed by biopsy 2/28/66. Note the progressive increase in the size of the lesion six months later (Figure 3), at which time she was referred for palliative radiotherapy.

Clinical Path Conference

Aortic Insufficiency and Bacterial Endocarditis

Dr. Francis J. Everhart:*

A 56-year-old mother of three was admitted to the hospital on June 22, 1966, because of bacterial endocarditis which had been recently diagnosed in her home community. A cardiac murmur was first discovered in 1950, but there was no history of rheumatic fever. After an episode of acute pulmonary edema in September, 1959, administration of digitalis and diuretics was begun and, with a few lapses, had been continued to the time of this, the final admission.

Nine days before the last admission the patient developed an upper respiratory infection and had chills, fever and a mild sore throat. Tetracycline of an unknown dosage was given orally for three days, ending June 15. Four days later, on June 19, there was recurrence of fever and chills, as well as malaise and headache. At this time the patient was hospitalized in her home community, at which time the blood pressure was 170 mm. Hg. systolic and 66 mm. Hg. diastolic. The pulse rate was 80 beats per minute and the body temperature was 104° F. Neither the spleen nor the liver was enlarged, and there were no petechiae. Blood cultures were done on June 19 and 20; both showed beta hemolytic streptococci. One gram of a tetracycline had been given intravenously on June 20. The patient was transferred on June 22, 1966.

Significant events in the medical history included several illnesses. A carcinoma of the colon had been resected in 1951, and there was no evidence of recurrence. A self-limited episode of pneumonia occurred in April, 1959. In 1964, partial loss of vision had been caused by occlusion of the left central retinal artery, and an anticoagulant (sodium warfarin) was administered. Subsequently the vision returned to normal, and treatment with anticoagulants was continued until the time of the final admission. There was a history of sensitivity to penicillin, and a few days

before this admission a severe rash had occurred after a test injection of penicillin intradermally. The patient had taken guanethidine for hypertension for some years.

Physical examination at the time of admission showed a moderately ill patient without peripheral cyanosis or edema. A few splinter hemorrhages were present under the toenails and fingernails. The blood pressure was 156 mm. Hg. systolic and 62 mm. Hg. diastolic. The pulses were regular and the rate was 100 beats per minute. The peripheral pulses were of a "collapsing" type, considered typical for aortic insufficiency. Pulsus alternans was noted by one experienced observer. A left parasternal heave was present, and the point of maximum cardiac impulse was in the left midclavicular line at about the sixth intercostal space. The first cardiac sound was normal and the second sound was single. A grade 3/6 systolic ejection-type murmur was present over the "aortic area" and radiated to the neck. Also, a grade 3/6 holodiastolic blowing murmur was heard along the left sternal border. Over the cardiac apex a prominent third sound and a diastolic rumble of the Austin Flint variety were present. The liver was not enlarged, but there may have been a small degree of splenic enlargement.

Ophthalmoscopic examination showed slight narrowing of the left retinal artery and arteriovenous nicking bilaterally. No retinal hemorrhages were seen.

Laboratory studies, done shortly after admission, gave the following results. The hemoglobin concentration was 14.3 grams per 100 ml. of blood. The total leukocyte count was 14,150 cells per cu. mm. The differential leukocyte count was: neutrophils, 79 per cent; lymphocytes, 12 per cent; and monocytes, 9 per cent. No phagocytic histiocytes were found. The hematocrit was 37 per cent and the reticulocytes numbered 1.1 per 100 erythrocytes. The platelet count was 200,000 per cu. mm. The erythrocyte-sedimentation rate was 107 mm. per hour. Subsequently, the sedimentation rate exceeded 100 mm. per hour several times.

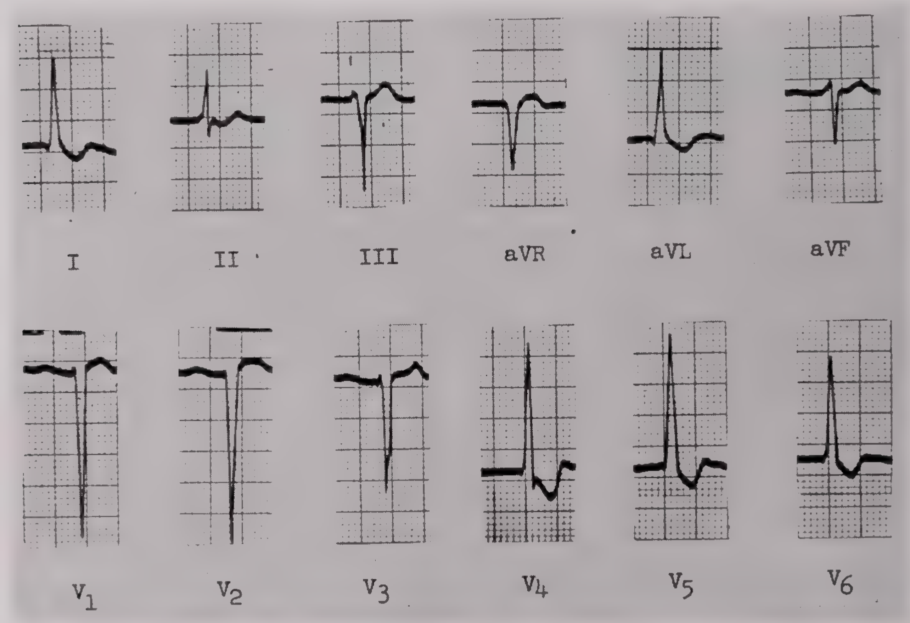

Fig. 1 — Electrocardiogram taken at the time of final admission.

Chemical determinations gave the following results: urea nitrogen, 24 (later study, 10); two-hour postprandial glucose, 64; the direct fraction of bilirubin, 0.2, and the total, 0.7; each in milligrams per 100 ml. of blood. The value for alkaline phosphatase was 9 Bodansky units. The concentration of albumin and globulin in the serum was 3.2 grams per 100 ml. and 3.8 grams per 100 ml., respectively. The VDRL test for syphilis was negative. Levels of serum lactic dehydrogenases were within the upper range of normal. The first test, which was done on the twenty-third hospital day, showed a value of 164 units for the heat stable fraction and 724 units for the total value. A second test, which was done four days later, showed values of 107 and 432, respectively. A third test showed no significant change. The concentration of creatinine was 1.1 mg. per 100 ml. of serum. The creatinine clearance tests gave normal values of 92 and 98 liters per 24 hours. The urine contained a trace of protein but was otherwise normal.

The first electrocardiogram showed left ventricular hypertrophy and strain (Figure 1).

With fluoroscopic examination of the thorax, calcification in the area of the aortic valve and left ventricular hypertrophy were observed. Wide systolic pulsations of the entire thoracic aorta were readily apparent. With barium in the esophagus, roentgenograms confirmed the presence of left ventricular hypertrophy (Figure 2).

Some of the pertinent clinical features are shown in Figure 3. This shows the highest temperature and the dosage of antibiotics, as well as the variations in hemoglobin concentrations and total leukocyte counts. Initially, antibiotics were not administered until blood cultures had been done several times. On the second hospital day the temperature rose to 104.6° F. and the patient had a shaking chill. At this time administration of antibiotics was begun with the following schedule: 3.0 grams of cephalothin, intravenously, every six hours, and 0.5 grams of streptomycin, intramuscularly, every 12 hours. Two blood cultures, which had been transferred with the patient, revealed beta streptococci, which were later found to be Group B beta hemolytic streptococci.

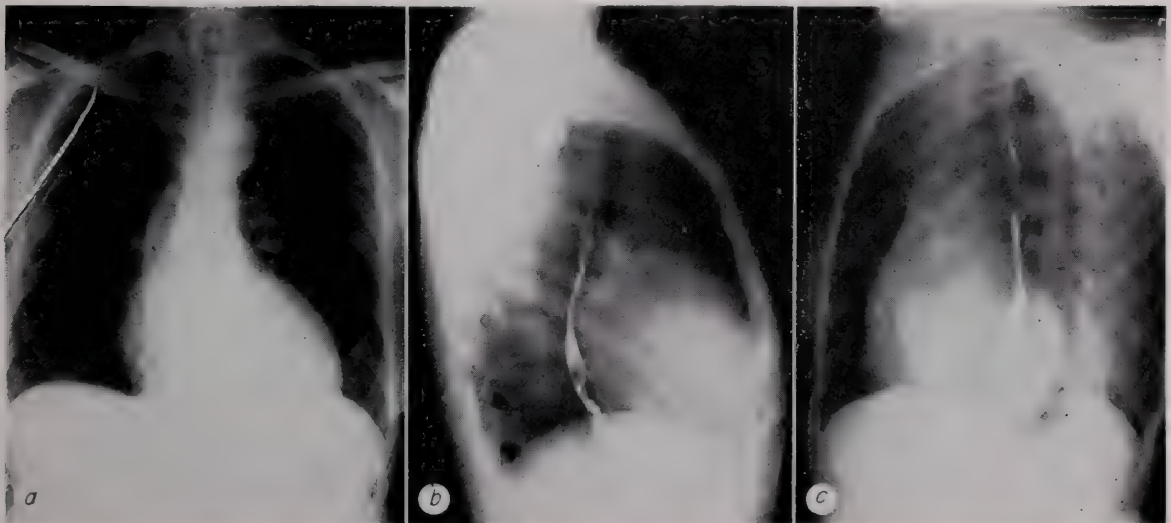

Fig. 2 — Roentgenograms of thorax. *(a)* frontal, *(b)* lateral, and (c) left anterior oblique views, respectively.

Continued

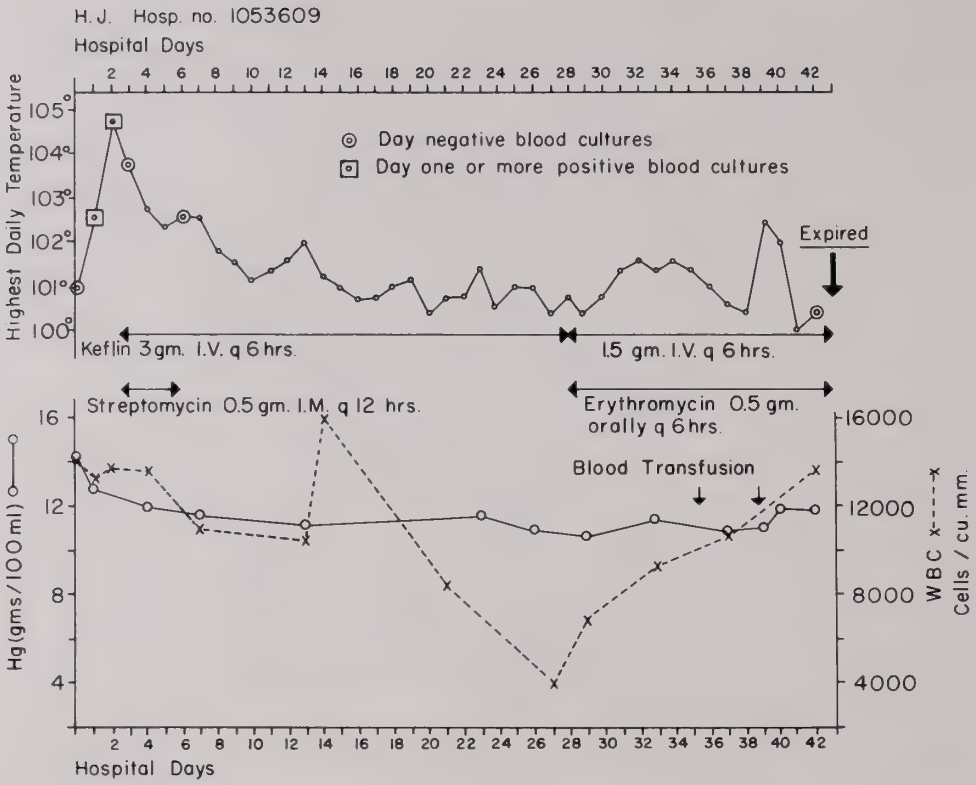

Fig. 3 — Summary of antibiotic treatment, results of blood cultures, and related response.

The organism's susceptibility to streptomycin, tetracycline, erythromycin and cephalothin is given in Table 1. Additional studies were done on a culture which was positive on the second hospital day, and this organism's susceptibility to penicillin, chloramphenicol, kanamycin, and lincomycin is also given in Table 1. The initial four cultures of the blood were sterile, whereas the succeeding six blood cultures, which were done during the first and second hospital days, were positive for Group B beta hemolytic streptococci. The colony count ranged from seven to 20 colonies per ml. of blood. After administration of antibiotics the blood remained sterile. The temperature fell somewhat, but remained above normal until the patient died. Administration of digitalis was stopped at the time of admission because sensitivity to this drug was suspected. After administration of digitalis was restarted on the tenth hospital day, it was necessary frequently to change the dosage because of rhythm disturbances. Beginning on the twenty-eighth hospital day, the patient had attacks of thoracic pain which appeared to be angina. The pain, which often occurred at night, was relieved by nitroglycerin. During this time the murmur of aortic insufficiency became more prominent. The hemoglobin concentration fell slowly and two blood transfusions were given. The second was followed by elevation of the body temperature to 102.4° F. During the evening of the forty-second hospital day the patient had an attack of severe thoracic pain which persisted for about one-half hour, despite the fact that three tablets of nitroglycerin were taken. The patient died several hours later.

Dr. James N. Karnegis will discuss the differential diagnosis.

TABLE I

Sensitivity to Antibiotics of Beta Hemolytic Streptococcus Recovered from Blood

Sensitive to	Resistant to

*Micrograms per liter.

Dr. James N. Karnegis:**

The history and physical examination indicate cardiovascular disease. The fact that the patient had been treated for carcinoma of the colon does not appear to be a factor in the final illness.

The acute nature of the illness is illustrated by the fact that only about seven weeks elapsed from the time the patient first developed symptoms to her death. It seems obvious that the major disease was severe infection. The referral diagnosis was bacterial endocarditis. The fever, chills, malaise and headache were consistent with that condition, and the diagnosis was made by the isolation of beta hemolytic streptococcus from the blood. No reference is made in the initial physical examination to the presence of a cardiac murmur, but the wide systemic arterial pulse pressure would be consistent with aortic reflux.

More physical findings of bacterial endocarditis were evident upon admission to the second hospital. Subungual splinter hemorrhages were noted. The statement about a suggestion of mild splenomegaly being present is of no value. However, clear-cut cardiac findings were described. A wide systemic arterial pulse pressure was again recorded together with the collapsing pulse of aortic insufficiency. This was further confirmed by auscultation of an aortic diastolic murmur. The aortic systolic murmur, while suggesting aortic stenosis, could also be caused by the increased stroke volume resulting from aortic insufficiency alone. The single second cardiac sound could represent stenosis of the aortic valve with resultant absence of an aortic valvular closure sound, or pulmonary hypertension with the pulmonic valve closing earlier than normal in the cardiac cycle, superimposing the pulmonic on the aortic component of the second sound. Pulmonary hypertension could have been caused by congestive heart failure, but we cannot be sure of this since no mention is made of examination of the lungs. Pulsus alternans generally is taken to indicate left ventricular decompensation, and the third heart sound is consistent with that. It is more likely, however, that the single second sound resulted from aortic valvular stenosis, since the elevation of pulmonary pressure in this case would not be expected to be of sufficient magnitude altogether to prevent respiratory splitting of the second cardiac sound. A left parasternal heave indicates right ventricular hypertrophy, but since there is no other evidence for right ventricular hypertrophy we cannot be certain that such a heave was

---

**Director, Maud Taylor Hill Cardiac Diagnostic Laboratory, The Charles T. Miller Hospital, St. Paul; Clinical Instructor of Medicine, University of Minnesota, Minneapolis.

Continued

actually present. A diastolic rumble was interpreted by the observers to be of the type heard in patients who have aortic insufficiency but not mitral stenosis. This murmur is believed to be caused by the aortic regurgitant jet of blood striking the anterior leaflet of the mitral valve and deflecting it into the pathway of blood being expelled in diastole from the left atrium into the left ventricle. The Austin Flint murmur mimics that of mitral stenosis but can be distinguished by other auscultatory findings. In mitral stenosis one would expect an accentuated rather than a normal first cardiac sound, and an opening snap rather than a third sound.

Laboratory studies showed mild leukocytosis and a neutrophilia. Renal and hepatic tests were normal. The erythrocyte-sedimentation rate is of diagnostic importance, being virtually always elevated in bacterial endocarditis, and was quite high in this case. The electrocardiogram showed a normal electrical axis in the frontal plane, left ventricular hypertrophy and digitalis effect. The normal sinus rhythm and absence of p mitrale provide some additional evidence to help exclude mitral stenosis.

Thoracic roentgenoscopy further defined aortic insufficiency by demonstrating marked pulsation of the thoracic aorta and left ventricular hypertrophy. Although the barium-filled esophagus is somewhat displaced in the region of the left atrium, it is probable that this is caused by left ventricular hypertrophy rather than pathological enlargement of the left atrium from mitral stenosis. Calcification was definitely seen in the aortic valve but not in the area of the mitral valve. Aortic valvular calcification is of key importance in this case and indicates calcific aortic stenosis.

Calcific aortic stenosis may be complicated by embolism, and this could explain some of the previous illnesses mentioned in the history. The occlusion of the left central retinal artery may have been embolic, and the systemic hypertension could have been produced by renal embolism. Since there is no definite evidence of mitral stenosis, the etiology of the aortic stenosis could well have been congenital rather than rheumatic. One would then expect a bicuspid or perhaps unicommissural aortic valve. A bicuspid aortic valve, whether congenital or acquired, is known to be fertile ground for the development of bacterial endocarditis. The aortic insufficiency displayed by this patient could have been related to the calcific stenosis with deformity and immobilization of the leaflets, thus resulting in incompetence. The aortic insufficiency could also have been caused by the endocarditis destroying valvular tissue with perforation or prolapse of the leaflets, or by vegetations interfering with coaption and closure of the leaflets.

Beta hemolytic streptococcus is a microorganism which often causes acute bacterial endocarditis. It is a virulent organism, and thorough treatment should be started immediately. Even when the infection has been eradicated the patient may still succumb, for example, to uncontrollable heart failure resulting from the valvular insufficiency produced by destruction of valvular tissue. Penicillin is generally the drug of choice. Although the microorganism was sensitive to this agent, unfortunately the patient was allergic to it. Under these circumstances, administration of penicillin, even when used in conjunction with adrenal steroids, is of high risk. The choice of antibiotics prescribed for this patient was reasonable, although streptomycin was given for only a brief period. Perhaps some would have employed a combination of antibiotics, adding another to which the organism was sensitive, probably choosing a bactericidal agent.

As mentioned earlier, even after eradication of the infection, death is sometimes produced by uncontrollable heart failure resulting from destruction of valvular tissue, but that did not appear to be the course here. The patient had angina relieved by nitroglycerin and died suddenly, suggesting involvement of the coronary arteries. Bacterial endocarditis of the aortic valve is the most common cause of coronary embolism, and this appears to be the most probable course of events in this patient. Furthermore, it is likely that the cardiac arrhythmias thought to be due to digitalis sensitivity earlier in the hospitalization were really caused by coronary emboli originating from the vegetations located on the aortic valve. Embolism is not related to the success of antibiotic therapy since it can occur for some time after the infection has been eliminated.

In conclusion, I believe that this patient had calcific aortic stenosis, probably on a congenital basis, with a bicuspid or unicommissural valve. The valve was insufficient after, and probably also before, the onset of acute bacterial endocarditis. Although the patient was treated for six weeks, she had angina pectoris and died suddenly, probably from coronary embolism originating from vegetations located at the aortic valve.

Dr. Michael E. Korns will present the pathologic findings.

Dr. Michael E. Korns:*

At necropsy the principal abnormalities involved the cardiovascular

Continued

system and, in particular, the aortic and mitral valves. The valvular lesions included chronic rheumatic aortic valvular endocarditis with insufficiency and bacterial endocarditis with perforation of each cusp. Also present were secondary bacterial endocarditis of the mitral valve and acute subendocardial infarction of the anterolateral papillary muscle of the left ventricle.

The heart was hypertrophied, weighing 595 grams. The degree of left ventricular hypertrophy was relatively greater than that of the right ventricle. There was patchy scarring of the left ventricular myocardium. Manifestations of congestive heart failure included generalized vascular stasis and hydropericardium (150 ml.). The aorta showed a severe degree of atherosclerosis.

The aortic valve was tricuspid. Each of the cusps was thickened and roughened, and there was a minimal degree of patchy calcification. Each cusp contained at least one perforation, but the posterior cusp contained four (Figure 4(a)). The contact surface of each cusp was surmounted by friable, grayish-tan vegetations. These were largest at the margins of the perforations through which the vegetations were continuous with vegetations on the sinus side of the cusps. The anterior leaflet of the mitral valve in its lower one third contained a perforation which measured approximately 0.5 cm. in diameter (Figure 4(b)). Obscure from the ventricular side of the leaflet (Figure 4(a)), the perforation was evident on the atrial side and was surrounded by vegetations which were similar to the aortic valvular vegetations. Additionally, there were vegetations deposited on the posteromedial commissure of the mitral valve.

The contiguous chordae tendineae had a ragged, lusterless appearance, and several were surmounted by small, yellowish vegetations. The mitral "ring" showed a small degree of calcification. There were jet lesions in the endocardium of the left ventricle; most of these were plaque-like, but several, in the central one third of the septum, took the form of small diastolic pockets (Figure 5).

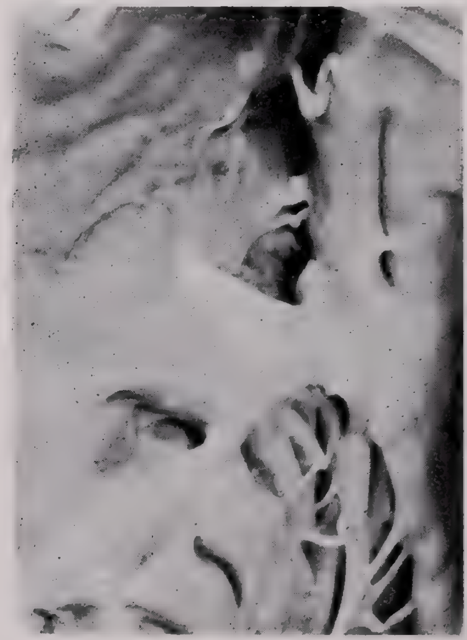

Fig. 5 — Endocardium of left ventricle. Endocardial pocket resulting from chronic aortic insufficiency.

The myocardium of the left ventricle, including the papillary muscles, showed patchy scarring, and the anterolateral papillary muscle was a mottled yellow; the gross appearance suggested acute infarction. The coronary arteries showed minimal atherosclerosis, and no coronary emboli were demonstrated either grossly or microscopically.

Histologically, the distortion of the aortic cusps was readily apparent (Figure 6(a) and (b)). The vegetations were engrafted upon cusps which were the seat of thickening with dense fibrous tissue containing small foci of calcification. Clumps of gram-positive bacteria, some of which formed short chains, were found in the aortic and mitral valvular vegetations (Figure 6(c)). Unfortunately, it was not possible to tell whether the organisms were viable. The infection was severe enough, however, to have caused an incipient aneurysm of one aortic sinus (Figure 6(a)) and a microabscess in the wall of the contiguous aorta (Figure 6(b)).

The atrial surface of the margin of the perforation in the anterior mitral leaflet showed nodular, confluent masses of acutely and chronically inflamed granulation tissue (Figure 7(a)), and there were several microabscesses in juxtaposition to the margin of the perforation. The process of infarction involving the anterolateral papillary muscle of

the left ventricle was quite recent and characterized by extensive areas of necrosis intermixed with viable muscle and small scars. In the majority of areas with necrosis the muscle fibers showed only eosinophilia without cellular infiltration. In other areas infiltration with polymorphonuclear leukocytes (Figure 7 (b)) was present.

Dr. Jesse E. Edwards will give a closing summary.

Dr. Jesse E. Edwards:*

From the pathologic findings and the clinical history it is evident that this patient had suffered from aortic insufficiency of rheumatic origin for some years. The chronicity of the aortic insufficiency is well supported by the fact that the heart was hypertrophied, weighing just under 600 grams. The occurrence of bacterial endocarditis in patients having antecedent valvular disease, often of rheumatic nature, is an accepted phenomenon. It is uncommon, however, that the antecedent disease is sufficient in degree to cause significant cardiac dysfunction. In this regard this patient's case is unusual, since there was evidence of congestive cardiac failure from aortic insufficiency preceding the occurrence of bacterial endocarditis.

The lesions of bacterial endocarditis in this case were characterized by extreme destruction of the aortic valve resulting in aortic insufficiency

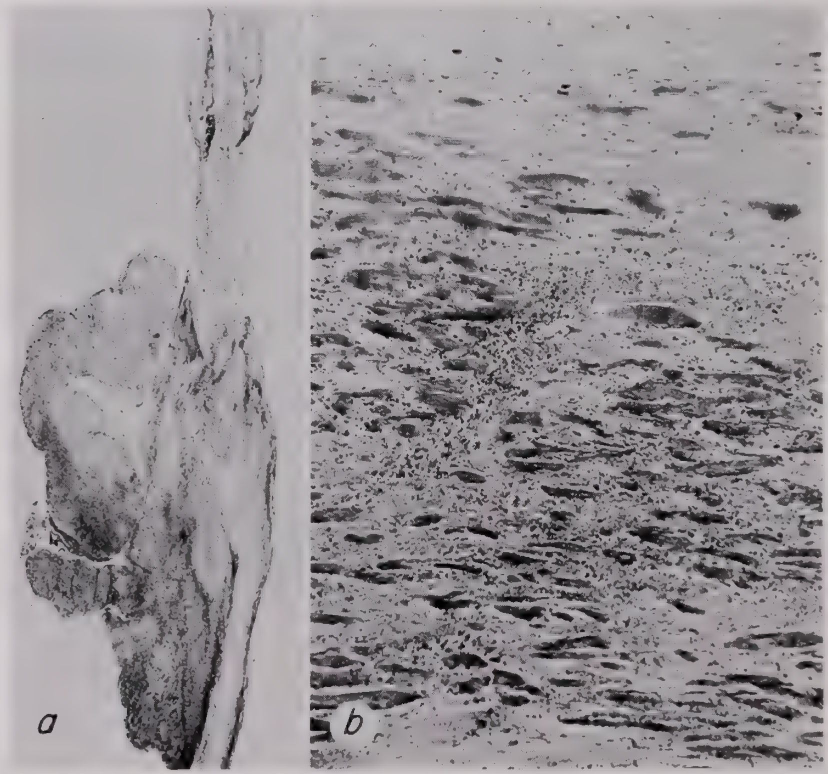

Fig. 7 *(a)* — Photomicrograph of anterior leaflet of mitral valve from section taken just peripheral to perforation shown in Figure 4 *(b)*. Nodular vegetations on atrial surface. on its own account. Coupled with the antecedent aortic insufficiency of rheumatic origin, the degree of incompetence of the aortic valve after the effects of the bacterial endocarditis were added must have been of severe proportion, accounting for significant mechanical disturbances in cardiac function in this patient, even though bacteriologic cure had been obtained. This is one of the tragedies of the present medical era when the patient with bacterial endocarditis may benefit from antibiotic therapy as far as the infection is concerned, but in some cases, as in this instance, the mechanical destruction caused by the active stages of bacterial infection leaves the patient with a serious mechanical defect in one or another cardiac valve.

The mitral valvular lesions in this case are of interest. It will be recalled that there was a perforation in the anterior mitral leaflet and a focus of infection in the posteromedial commissure. Each of these lesions is considered to have resulted from aortic valvular insufficiency, while active infection of the aortic valve was present. Infected blood which regurgitated had impacted against the underlying mitral valve to cause the secondary foci of infection in the mitral valve. In this particular case the perforation of the anterior mitral leaflet was relatively small and of itself did not contribute to any significant cardiac dysfunction. In other cases a similar phenomenon results in a gross defect in a leaflet of the valve. In some cases rupture of mitral valvular chordae may be the significant mitral valvular complication of regurgitation through an infected aortic valve. It is to be emphasized that in some cases of aortic valvular endocarditis the secondary effects upon the mitral valve may be more significant than those upon the primarily involved aortic valve.

The myocardial lesions observed in this case were characterized by acute infarction which was localized in the anterolateral muscle of the left ventricle. When bacterial endocarditis involves a valve in the left side of the heart, embolism of vegetative material into the coronary system is common. This often results in focal, microscopic-sized infarcts of the myocardium. In this particular case the basis for localization of infarction to the anterolateral papillary muscle is not clear. One possibility is that coronary embolism (although no such lesions were observed) was concentrated in the zone that became infarcted.

Drs. Ernesto Arosemena and James H. Moller and I demonstrated that there is a tendency for infarction of the left ventricular papillary muscles in instances of left ventricular hypertrophy, whatever the cause. It is possible that the infarction of the anterolateral papillary muscle observed in our case was a manifestation of this phenomenon. While mitral insufficiency was not demonstrated in our patient, it is possible that this disturbance had in fact been present as a result of the demonstrated involvement of the anterolateral papillary muscle of the left ventricle.

It will be recalled that calcification of the aortic valve was described during the roentgenoscopic examination. Although calcific foci were found in this valve during the pathologic examination, the degree of such involvement seemed inadequate to have been visible by roentgenoscopic examination. Also, it is questioned whether the minor degree of

Continued

calcification of the mitral "ring" could have been visible and so confused with aortic valvular calcification.

Final Anatomic Diagnosis

Rheumatic aortic valvular insufficiency with complicating bacterial endocarditis.

Old Medical Equipment Needed

Minneapolis People to People are sponsoring a drive for used or repairable medical equipment and supplies which will be sent to Santiago, Chile, the Sister City of Minneapolis.

Equipment will be distributed by the medical faculty of the University of Chile to poor hospitals in the entire country. There is a dire need for any equipment or supplies that can be repaired to a useable condition. Conditions in many areas are such that patients are sometimes placed two to a bed, as in the case of women's confinements. In many cases there is a total lack of hospital facilities.

Doctors are asked to bring the material to the hospitals, which are serving as collection points. If the equipment is too large to be transported, please call Joe Paulson of the Jaycees at Swedish Hospital X-Ray department (333-4171) in Minneapolis.

Surgical Meeting

A dinner meeting of the Minneapolis Surgical Society will be held December 1 at the Minneapolis Club in Minneapolis at 6:00. The following speakers will be guests of the Society for that evening:

George C. Hottinger, M.D. — "Cushing Syndrome — Surgical Perspective With Report of a Case"

Michael F. Lynch, M.D. — "The Typical, Atypical, and "Atypical" Ductus Arteriosus in Infants and Children. Surgical Consideration in 23 Consecutive Cases"

On Quaffing

A man who tries to drown his troubles in drink usually finds he has only irrigated them. — The Link

Tussagesic breaks up coughs, quickly clears stuffed and runny noses and relieves aches and pains. Provide coverage of the tough cold for up to 24 hours with just a single timed-release tablet dosed morning, midafternoon and at bedtime.

each

Tussagesic®

timed-release tablet contains:

Triaminic® (phenylpropanolamine hydrochloride 25 mg., pheniramine maleate 12.5 mg., pyrilamine maleate 12.5 mg.)	50 mg.
Dextromethorphan hydrobromide	30 mg.
Terpin hydrate	180 mg.
Acetaminophen	325 mg.

Dosage: Adults—1 tablet, swallowed whole to preserve timed-release feature, in morning, midafternoon and at bedtime. *Side effects:* Occasional drowsiness, blurred vision, cardiac palpitations, flushing, dizziness, nervousness or gastrointestinal upsets. *Precautions:* The patient should be advised not to drive a car or operate dangerous machinery if drowsiness occurs. Use with caution in patients with hypertension, heart disease, diabetes or thyrotoxicosis.

Medical Seminar

Complications of Stapedectomy

Presented as a Seminar
Sponsored by
The Faculty of the Mayo Graduate School of Medicine

USUALLY STAPEDECTOMY is a very successful surgical operation, but occasionally complications occur that tax the surgeon and distress the patient. These complications may be divided into those that are apparent during the surgical procedure and those that are manifest in the postoperative period.

Complications Apparent During the Surgical Procedure

Bleeding

Excessive bleeding can make stapedectomy a difficult and miserably prolonged procedure. The cause of the problem may be hypertension, either primary or due to anxiety, an excessively prolonged operation, or an unsuspected blood dyscrasia. Otosclerotic foci in the young person or in any person in whom there is highly active otosclerotic disease are inclined to bleed excessively. These problems are more easily forestalled than treated, once they have been allowed to develop. Adequate premedication to allay anxiety, a properly placed circumferential canal-skin injection of lidocaine and 1:100,000 adrenaline, restriction of operating time to less than 45 minutes, and full use of suction irrigation and diamond-dust burrs for bony bleeders are all advised.

Injuries and Abnormalities of the Incus and Malleus

The most common ossicular injury sustained during stapedectomy is dislocation of the incudomalleal* joint. Dislocation is caused either by poor control of the curette when bone from the posterosuperior canal wall is removed or by uncontrolled manipulation within the middle-ear cavity. Sometimes the dislocation may be reduced from below; at other times[1] the epitympanum must be exposed further and the incus replaced in its correct articulation.

Abnormalities of the incus and malleus are uncommon. They include absence of the long process of the incus (usually destroyed by infection), absence of the entire incus, and fixation of the head of the malleus to the roof of the epitympanum by a bony spur. The partial or complete loss of the incus presents the operator with the problem of where to attach the strut of the prosthesis. Usually the surgeon compromises successfully by attaching the strut to the handle of the malleus. Routine assessment of the mobility of the ossicular chain should enable the recognition of a fixed mallear head.

Problems at the Footplate

The "Floating Footplate."—During the removal of the superstructure of the stapes, the footplate sometimes becomes mobile and free. In this situation the footplate resists attempts at removal by shifting away and causing waves of pressure in the perilymph, thus damaging the inner ear. To deal with this problem, House[1] advised that, with a fine sharp needle, a small hole be made in the footplate prior to removal of the superstructure. The hole prevents traumatizing suction on the membranous labyrinth during elevation of the footplate. A thicker footplate may be impossible to perforate with a needle; in this case, extremely cautious use of a footplate drill is necessary.

The "Obliterated Footplate."—Here the annular ligamentous margins of the stapes may be obscure and the otosclerotic over-

Continued

---

*See Test Your Word Score Page 1719.

growth marked. More commonly, the margins of the ligament may be distinct and the footplate not too abnormal. It is fortunate that the obliterated footplate is uncommon, because after stapedectomy the incidence of postoperative sensori-neural hearing loss and regrowth of otosclerotic foci with secondary closure of the oval window are discouragingly high.

McGee[2] stated the belief that obliterated footplates are handled best by drilling a small hole in the center of the footplate and inserting a stainless-steel piston. House[1] advised not to remove areas of otosclerosis that abut on the promontory, the facial nerve, or the sides of the oval window. He believes, as do many others, that otosclerosis is activated by trauma. If the footplate of the stapes has previously been operated on and bony closure is discovered at a subsequent operation, a secondary removal of the "footplate" is considered so likely to produce cochlear loss that many surgeons advise that no further surgery be performed on the footplate.[1,3]

Free Footplate Fragments.—The footplate may break up during removal, and a fragment or sometimes an entire footplate may drop into the vestibule. Tiny fragments are usually not a concern, but expert opinion is divided on what to do about large ones.

In their experience, Cawthorne[4] and Portmann[5] found that if large fragments are left in the vestibule very poor hearing usually results. House[1] believed that large fragments cause no more than persistent positional vertigo.

A fragment large enough to be seen probably should be removed, but blind probing seems far too likely to cause permanent damage to the inner ear to be advised. Manipulation in the vestibule should always be stopped if vertigo occurs.

Anthony[6] pointed out that the white utricular macula deep to the superior rim of the oval window may simulate a bone fragment. Naturally, it is disastrous to remove this "fragment."

Profuse Perilymph Leakage

This is an unusual event. In extreme cases, perilymph gushes from the oval window and fills the middle ear and sometimes even the external auditory canal. The etiologic possibilities include a large cochlear aqueduct, a fissure in the otic capsule, and a fracture of the lamina cribrosa* with an instrument. Shea[3] reported 17 instances of such leakage in a series of 780 patients. The condition is usually controllable at surgery by Gelfoam packing plus muscle or vein packing as well. Coverage with antibiotics for five to seven days afterward is strongly recommended. Cawthorne[7] advised reoperation if the perilymph drainage has not ceased within a few days after operation. Patients with excessive perilymph leakage during operation possibly are more likely to have a footplate fistula later. These patients should be closely followed and, if an infection of the upper respiratory tract develops, treatment should be vigorous because of the potential danger of labyrinthitis.

Complications Apparent in the Postoperative Period

Disturbances of Taste and Oral Sensation

There is a surprising lack of agreement as to how troublesome the symptoms are that result from injury of the chorda tympani nerve during stapedectomy. House[1] stated that sectioning, partial tearing, or even stretching of the chorda tympani may cause the common postoperative symptom of metallic taste on the anterior two thirds of the tongue or soreness or dryness of the mouth. These symptoms usually subside in three to four months.

Bull[8] reported that unilateral section of the chorda tympani resulted in 32% of 126 patients having persistent symptoms of metallic taste or soreness after one year, whereas only 7% of 100 patients had persistent symptoms at the end of one year when the chorda tympani had been preserved. He believed that the common practice of sectioning the suspected stretched nerve to avoid troublesome oral discomfiture was irrational, as such discomfort rarely occurred after nerve stretching. He stressed that 78% of patients in his series had permanent symptoms if both chorda were cut. These patients have dry mouth and total lack of taste on the anterior two thirds of the tongue. There are no known cases of the taste buds originally supplied by the chorda tympani nerve being reinnervated by the glossopharyngeal nerve. Thus, every effort should be made to preserve the chorda tympani nerve, especially if the opposite one has previously been sectioned.

---

*See Test Your Word Score Page 1719.

Equilibrium Disturbances

These do not appear to be a common problem, according to the reports of most otologists, although the patient has a period of hesitancy when moving his head suddenly and has slight imbalance when walking; this occurs after even the most atraumatic stapedectomy and clears quickly.

Shea[3] discussed another entity — postural giddiness after stapedectomy. The patient finds that tilting his head backward or somewhat to the side causes violent transitory vertigo. Shea believed that this is utricular in origin and could possibly be caused by a bone fragment irritating the utricle. Shea[3] believed that aviators, steeplejacks, and others who require a perfectly functioning vestibular labyrinth to do their jobs need to be warned, before operation, of this risk.

A prosthesis that is too long is a well-known cause of postoperative, persistent equilibrium dysfunction. House[1] suggested that the distance between the footplate and the incus be measured routinely and that the prosthesis be tailored accordingly.

Problems of Infection

Otitis media occurs occasionally after stapedectomy. Routine postoperative treatment with antibiotics probably suppresses otitis media that might otherwise occur. Several instances of meningitis, sometimes months after stapedectomy, have been reported, and there have been a few consequent fatalities. Preceding the onset of meningitis, the patient often has had a head cold and has created a situation whereby increased intratympanic pressure — such as flying, driving a car in the mountains, underwater diving, or blowing the nose vigorously — has caused rupture of the foot plate prosthesis, with the subsequent ingress of contaminated material from the middle ear. Shea[3] has reported a case of mastoiditis from *Proteus* organisms and of subsequent jugular foramen syndrome* after a stapes-mobilization procedure in the presence of external otitis. After a stormy course, the patient recovered.

According to House,[1] the tympanic membrane ruptures before the Gelfoam-based, oval-window membrane does when infected material is present in the middle ear. This is a fortunate event and prevents otitis media from being a very dangerous complication of stapedectomy.

To decrease the possibility of otitis media after stapedectomy, diving and unpressurized-air travel should not be permitted, although swimming and pressurized-air travel can be.

Anthony[6] emphasized that an ounce of prevention with scrupulous preoperative preparation of the ear canal and exacting operative technique is worth a pound of cure. Wright and Marmesh[9] have had only one case of otitis media in 2,749 cases of stapedectomy, after preoperatively treating the canal skin with iodine.

Facial Nerve Palsy

Facial nerve paralysis occurring after stapedectomy is rare. The palsy may be caused by trauma or by the local effect of lidocaine upon an exposed facial nerve within a dehiscent facial canal. In the latter instance, the function of the muscles of the face should completely recover within the first six hours after operation.

The function of the facial nerve must always be assessed immediately after stapedectomy, because if the function is normal and a palsy develops later, the treatment is different from that advocated if paralysis is noted at the end of the operation and is unchanged after a period of six hours' observation.

A delayed palsy commonly is partial, and recovery usually occurs in one to three weeks. The pathologic process underlying it undoubtedly is neurapraxia. A patient

Continued

---

*See Varnet's Syndrome Page 1676.

with this type of paralysis should be observed and not immediately reoperated on.

The immediate postoperative palsy may be handled conservatively, too, but only if the operator is sure that he did not severely damage the facial nerve. Most surgeons usually are not certain, however, of the extent of the injury that causes an immediate postoperative palsy, and when doubt exists they advocate early exploration of the facial nerve. An impacted bone chip or a hematoma may be the cause of the palsy; the remedy is removal. When the nerve has been severed, it may be possible to approximate the ends. Nerve grafting is indicated if a gross breach in the continuity of the nerve exists.

Subsequent Hearing Losses

These losses are often classified as either immediate or late, but perhaps can be grouped more informatively as conductive losses or sensori-neural losses.

Conductive Losses

These are nearly always caused by technical errors. The prosthesis may slip off the long process of the incus if the attachment is loose. A prosthesis that is tightly attached to the incus may cause incudal necrosis and subsequent disruption of the ossicular chain. Polyethylene struts were particularly bad in causing incudal necrosis and are not used now. A prosthesis that is too short prevents an effective oval-window seal, and a conductive loss results. Conductive losses that occur in the early postoperative period are usually due to the reactionary serous otitis that is so often seen after stapedectomy or tympanotomy. In reactionary serous otitis, awaiting the resolution of the fluid is regarded as the best decision. Myringotomy and suction removal of the fluid is advocated by House,[1] if the conductive loss is persistent. Later in the postoperative period, bony reclosure of the oval window or, rarely, calcification in the graft material may cause a delayed conductive loss.

Sensori-neural Losses

Immediately after stapedectomy, minor degrees of high-tone, sensori-neural loss that are not permanent are probably due to slight trauma to the hair cells of the organ of Corti. Severe to complete sensori-neural hearing loss, although embarrassing to the surgeon and unfortunate for the patient, does not occur often. Cody and associates[10] reported that 1.9% of their 639 patients had profound sensori-neural loss six months after operation. These patients were operated on between 1960 and 1963. By far the lowest incidence of severe sensori-neural loss was reported by Hough.[11] He has performed partial stapedectomy and believes that lack of trauma associated with this technique explains his excellent results.

Much statistically based discussion and rather less animal experimentation have led to the incrimination of the following factors as contributory to profound sensori-neural loss: trauma, infection, bleeding, bone chips or dust, graft material, any revision operation, "drill-out" operations, stapedectomy after fenestration, extremes of age of the patient, and loss of the stapedius reflex.

Trauma has been suggested as a cause because the incidence of sensori-neural loss decreases as the operator gains experience. Experimentally, Schuknecht and Tonndorf[12] have shown that excessive manipulation of stapes can result in injury to the organ of Corti in the upper basal turn of the cochlea of the cat, thus creating a lesion identical to that from a high-intensity blast or head injury. Hohmann[13] demonstrated that direct trauma to the membranous labyrinth in the vestibule often results in widespread labyrinthine reactions; the reactions vary from mild labyrinthitis to a severe reaction that is followed by invasion of the labyrinth with connective tissue and bone.

Shea,[3] in support of the theory that infection causes labyrinthitis and sensori-neural loss, stated that a large percentage of ears with such loss had, at repeat operation, massive adhesions in the oval window niche around the graft and the prosthesis.

House[1] believed that blood in itself does not cause cochlear hearing loss. Bleeding, however, may lead to further surgical trauma by poor visualization, longer operating time, and prolonged use of suction. Hohmann[13] has shown that blood can be injected into the inner ear of cats without inner-ear complications. Shea[3] has noted that, whether bleeding is a cause or an effect, profuse bleeding occurs more often in ears that undergo further cochlear loss.

While at one time it was believed that bone dust or chips probably could prove irritating to the cochlea and cause sensori-neural loss[14] by a theoretic interreaction of labyrinthine fluid and bone protein and inorganic ions, it now seems generally agreed that bone chips do not cause inner-ear damage provided they do not injure the membranous labyrinth mechanically.

The possibility of a graft material such as a Gelfoam prosthesis being more likely than other graft materials to perforate and cause a fistula, resulting in inner-ear infection and subsequent hearing loss, has been refuted by House's[1] excellent results with this material.

Although fat, vein, and fascia have been used extensively in previous years, there has been a trend to use Gelfoam more and more as the graft material to cover the oval window. The switch was based in part on the better results obtained by surgeons who used Gelfoam than by those who used tissue material. Theoretically, too, Gelfoam can be kept sterile more easily than can fat, fascia, or vein. Toxic products of degeneration from the fat, fascia, or vein and a foreign protein reaction have been postulated as causing hair-cell damage.[15] In experiments recently performed on cats, however, Hayden and McGee[16] could not definitely incriminate any factor in fat grafts. The final answer to the question of the superiority of Gelfoam as compared to tissue grafts will be found in the results of the long-term, follow-up studies of the use of Gelfoam by the average otologist.

Shea[3] reported that 11.1% of 61 patients had cochlear loss at a one-year follow-up of a series of repeat operations on the same ear with Teflon. Other surgeons had cited similar experiences with revision operations.

After primary "drill-out" procedures for obliterative otosclerosis, Shea[3] found a 10% incidence of profound sensori-neural loss in 186 patients at the end of three years. Recently, Sooy and associates[17] reported that four (6.3%) of 64 patients had a discrimination loss of as much as 10% four months after "drill-out" procedure.

Shea[3] reported a 9.1% incidence of cochlear loss after stapes surgery that followed earlier fenestration. He believed that the added trauma of a secondary operation as well as infection from the mastoid bowl are both causative factors.

Shea[3] cited appreciably higher incidences of sensori-neural loss in patients at the extremes of life. The reason for this is not definitely known.

Exposure to loud noise after loss of the damping effect of the stapedius muscle through its routine section at stapedectomy theoretically entails a greater risk of sensori-neural loss. Cawthorne[7] advised the wearing of cotton wool or ear plugs during exposure to loud noise for several weeks or months after stapedectomy.

Summary

In summary, complications are associated with stapedectomy, but these are usually minor. The dreaded problem of further sensori-neural hearing loss is nearly always associated with excessive surgical trauma. Long-term follow-up studies to determine the best techniques along with careful planning and attention to surgical detail should improve the percentage of successful results.

Butazolidin® alka

phenylbutazone, 100 mg.
dried aluminum hydroxide gel, 100 mg.
magnesium trisilicate, 150 mg.
homatropine methylbromide, 1.25 mg.

Usually works within 3 to 4 days in osteoarthritis

The trial period need not exceed 1 week. In contrast, the recommended trial period for indomethacin is *at least 1 month.*

That's why it's logical to start therapy with Butazolidin alka—you'll know quickly whether or not it works. And usually, it will.

A large number of investigators have reported major improvement in about 75% of cases. Some patients have gone into remission. Relief of stiffness and pain may be followed quickly by improved function and resolution of other signs of inflammation. And Butazolidin alka is well tolerated, especially since it contains antacids and an antispasmodic to minimize gastric upset.

Contraindications
Edema; danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. Because of the increased possibility of toxic reactions, the drug should be used with greater care in the elderly and should not be given when the patient is senile or when other potent chemotherapeutic agents are given concurrently. Large doses of Butazolidin alka are contraindicated in patients with glaucoma.

Warning
If coumarin-type anticoagulants are given simultaneously, the physician should watch for excessive increase in prothrombin time. Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea, sulfonamide-type agents and insulin. Patients receiving such concomitant therapy should be carefully observed for this effect.

Use with caution in the first trimester of pregnancy.

Precautions
Before prescribing, the physician should obtain a detailed history and perform a complete physical and laboratory examination, including a blood count. The patient should be kept under close supervision and should be warned to report immediately fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools. Regular blood counts should be made to guard against blood dyscrasias.

Adverse Reactions
The most common adverse reactions are nausea, edema and drug rash. Moderately lowered red cell count may sometimes occur due to hemodilution. The drug has been associated with peptic ulcer and may reactivate a latent peptic ulcer. Infrequently, agranulocytosis, exfoliative dermatitis, Stevens-Johnson syndrome or a generalized allergic reaction may occur and require withdrawal of medication. Stomatitis, salivary gland enlargement, vertigo or languor may occur. Leukemia and leukemoid reactions have been reported but cannot definitely be attributed to the drug. Thrombocytopenic purpura and aplastic anemia are also possi side effects.

Confusional states, hyperglycemia, agitatio headache, blurred vision, optic neuritis and transient hearing loss have been reported, have hepatitis, jaundice and several cases anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently.

Dosage
The initial daily dosage in adults is 300-600 mg. daily in divided doses. In most instance 400 mg. daily is sufficient. When improveme occurs, dosage should be decreased to the minimum effective level: this should not exceed 400 mg. daily, and is often achieved with only 100-200 mg. daily.

For complete details, please refer to full prescribing information.

Grand Rounds

Inappropriate Secretion of Antidiuretic Hormone[*]

ROGER STENLUND, M.D.
Medical Resident

HYPONATREMIA[**] IS encountered frequently in clinical medicine. This finding in itself has little value unless correctly interpreted in light of accompanying data.

Hyponatremia usually occurs in three main settings:

a. Hyponatremia associated with circulatory insufficiency and an overexpanded extracellular fluid volume. Congestive heart failure, the nephrotic syndrome, and severe hepatic disease are examples.

b. Hyponatremia with circulatory insufficiency and a contracted extracellular fluid volume, as may be seen with overzealous diuretic therapy, severe gastrointestinal electrolyte losses, excessive perspiration losses, renal disease and adrenal failure.

c. Hyponatremia associated with an adequate circulation and an expanded extracellular fluid volume.

The latter situation is of major interest in this paper as it exists in two circumstances — the syndrome of inappropriate antidiuretic hormone secretion and its experimental prototype of prolonged administration of exogenous antidiuretic hormone and water.

Antidiuretic Hormone

Neurohypophyseal extraction yields a relatively pure protein with a molecular weight of 30,000, which can be divided into antidiuretic hormone and oxytocin. Both are octapeptides with antidiuretic hormone being arginine — vasopressin, the antidiuretic hormone common to all mammals except swine.

Antidiuretic hormone is probably produced in cells of the supra-optic and paraventricular nuclei and liberated from the terminations of axons of the supra-optico-hypophyseal tracts in response to impulses from these same nuclei or elsewhere in the hypothalamus.[1]

Continued

The Normal (Appropriate) Schema of Antidiuretic Hormone Secretion and Action

Extracellular fluid osmolarity and perhaps also extracellular fluid volume appear to be the most important of the many factors regulating ADH secretion. Changes in extracellular fluid osmolarity of as little as ±2% are postulated to be sensed by osmoreceptors located somewhere within the distribution of the internal carotid arteries, perhaps in the supra-optic nuclei themselves. In response to increased tonicity antidiuretic hormone is liberated and with decreased tonicity the converse occurs. Impulses from volume receptors within the thorax may also influence the release of antidiuretic hormone.

Antidiuretic hormone is liberated in response to many other stimuli, including pain, fear, syncope, apprehension, exercise, smoking, and various drugs — central nervous system depressants (especially morphine, ether, and the barbiturates), nicotine, epinephrine, histamine, acetylcholine, and adenosine-triphosphate.

Likewise, antidiuretic hormone release is inhibited by several factors: alcohol, left atrial distention, hypnotic suggestion of water drinking and conditioned-reflex diuresis.

This variety of factors implies the presence of a central integrative mechanism which receives and integrates these various impulses and then relays stimulation or inhibition of antidiuretic hormone release.

Three Direct Renal Effects:

a. To increase the permeability of the distal convoluted and collecting tubules to water.

b. To stimulate the transfer of sodium into the renal interstitium at the loops of Henle.

c. To regulate the rate of medullary and papillary perfusion by the vasa rectae.

The cumulative effect augmenting water reabsorption and inhibiting excretion of free water. Under maximal stimulus, the urine may reach an osmolarity of approximately 1,400 mOm-L or 3-5 times that of serum.

The basic action of antidiuretic hormone is, therefore, to maintain the osmolarity of body fluids within close limits — i.e. 290 ± 10 mOm/L for serum.

Mechanism for Maintaining Body Fluid Osmolarity:

a. Afferent impulses — probably from several sites in response to several stimuli.

b. A central integrative mechanism assimilating these impulses.

c. The neurosecretory mechanism responsible for antidiuretic hormone.

d. Renal effect or mechanisms which govern water excretion accordingly.[1,2,3]

Syndrome of Inappropriate Secretion of Antidiuretic Hormone

Background Material

Early data by Leaf et al.[5] provided evidence that electrolyte deficit induced by antidiuretic hormone was probably a reflection of water retention more than urinary loss.

Jaenike and Waterhouse[6] found that with a high fluid intake with steady sodium intake (approximately 110 mEq/day) there occurred an initial rapid expansion of total body water associated with an excessive urinary excretion of sodium. After the sixth day of this response, urine osmolarity slowly decreased, urine volume increased and body water balance was reestablished with a concomitant decrease in natruresis,* but with a continuing state of over-expansion of body fluid volume. In spite of continued antidiuretic hormone and water, a new steady state was achieved characterized by persistent overhydration and hyponatremia. This suggested that duration of the overhydrated state was a critical factor in an apparent renal unresponsiveness to continued antidiuretic hormone. This never occurred prior to the seventh day of antidiuretic hormone and water administration. Urine osmolarity progressively fell from a high on day one of 800 mOm/L to values only slightly hypertonic to plasma. Sodium excretion decreased to the point that positive sodium balance was achieved. There was a subsequent three-day period of water retention with value series identical to those obtained during the initial response. Despite continued vasopressin at higher doses, water balance was again achieved at a body weight approximately 5 kg. greater than control weights.

A variant study, similar to the above but with sodium restriction (approximately 32 mEq/day), revealed a similar response pattern, but natruresis was less marked.

These subjects experience mild nausea and headache during periods of maximal water retention, and one had mild ankle edema.

In a subsequent study it was observed that water retention and natruresis were directly related to water intake — being slight at 1,000 cc/day and marked at 2,000 cc/day. On two occasions they were able to achieve net loss of water by the use of mannitol.* In the latter study after periods of lower fluid intake, the urine became actually hypotonic to plasma, whereas in the first study, urine osmolarity was persistently greater than that of plasma. Sodium excretion also tended to parallel sodium intake, but natruresis could not be abolished by sodium restriction alone.

Additional studies allowing intake of 3,150 cc/day had to be discontinued because of severe nausea, vomiting, headache and lethargy.

The occurrence of decreasing urine tonicity associated with a stable but overhydrated state suggests that a state of overhydration could exist without a true, significant sodium-losing state.

They concurred with Leaf that the hyponatremia was due to dilution more than to sodium loss.

The Clinical Syndrome

In the majority of cases the syndrome of inappropriate antidiuretic hormone is entertained after the incidental finding of hyponatremia. The syndrome should be considered strongly with the preliminary data of hyponatremia, absence of edema and normal blood urea nitrogen. The diagnosis can then be pursued in a more definitive manner. Since there is no readily available and accurate method of antidiuretic hormone measurement, the diagnosis is primarily inferential, initially resting upon the clinical picture and supporting laboratory data and finally upon a response

---

*See Test Your Word Score Page 1719.

Continued

to management consistent with that anticipated with the syndrome of inappropriate secretion of antidiuretic hormone.

Several features of this syndrome are characteristic:

a. Hyponatremia without evidence of vascular collapse or significant edema.

b. Extracellular fluid volume usually greater than normal.

c. No evidence of renal or adrenal malfunction.

d. Tendency to increased glomerular filtration rate and low or normal blood urea nitrogen.

e. Urine osmolarity usually consistently greater than serum osmolarity.[7,8]

Differential Features

The initial differential diagnosis includes the other causes of hyponatremia previously mentioned and should pose no difficulty. Probably the most difficult differential is the stage of adrenal insufficiency in which the water-excreting defect is more profound than the salt-losing defect, leading to hyponatremia without apparent body-fluid volume contraction. This may occur, for instance, in non-addisonism patients who are taking steroids for asthma, rheumatoid arthritis, etc., and then have abrupt discontinuance of steroid.[9] In the interests of a definitive diagnosis of this syndrome specific endocrine function and renal function and fluid space determinations should be performed.

Pathophysiology and Other Features of This Syndrome

The "inappropriateness" relative to this syndrome is the secretion of antidiuretic hormone or at least a state of antidiuresis in the absence of the previously mentioned "normal appropriate" stimuli.

Conditions similar to those features of this syndrome have been reported with many disease states, most of which have been intrathoracic or intracranial.

Intrathoracic Diseases:

Neoplasms — majority are oat-cell carcinoma.

Tuberculosis.

Williams et al.[10] published data from a case of oat-cell carcinoma involving the hilum of the lung associated with this syndrome. Utilizing special histochemical staining techniques, they found morphologic changes in the cells of the hypothalamic nuclei and posterior pituitary which were considered indicative of neurosecretory exhaustion due to prolonged secretion of ADH. They do not comment on the possibility that these changes might indicate some other functional state, such as decreased neurosecretory function due to an ectopic secretory focus. Cell counts of the anterior pituitary were felt to be indicative of enhanced adrenocortical activity, and bilateral adrenal hyperplasia was found at autopsy. Adrenal function studies were said to be normal.

Amatruda et al.[11] performed bio-assay techniques for antidiuretic activity on portions of an oat-cell carcinoma from a patient who had exhibited the syndrome of inappropriate antidiuretic hormone. They found an average activity of 212 U.S.P. micro-units of arginine — vasopressin equivalence per mg. of dried tumor. This amount was small compared with that present in normal antidiuretic hormone neurosecretory sites, but they felt that the large total mass of the tumor may have produced functionally significant amounts. Of interest is that they also assayed the activity of tissues from patients with diseases associated with inability to excrete a water load. Tissue from a patient with cirrhosis was inactive. However, hilar lymph nodes from a patient with a demyelinating disease of the central nervous system contained 53 antidiuretic hormone-activity units/day. Hilar lymph nodes from patients with carcinoma of the prostate and sarcoidosis also revealed 20 and 50 antidiuretic hormone-activity units, respectively. Tissue from other cases was negative.[13,6] Histochemical studies as mentioned above would have been of interest in the patient whose tumor demonstrated antidiuretic hormone-like activity. It is not known if the demonstrable activity was due to actual antidiuretic hormone production or to other possible explanations such as an active polypeptide with its own antidiuretic action, or to release of antidiuretic hormone from the bioassay animal (not hypophysectomized) or perhaps ab- or adsorption of antidiuretic hormone by the tumor.

Diseases of, or Including the Central Nervous System:

Neoplasm.
Vascular disease.
Head trauma.
Malformation.
Undiagnosed.
Meningitis.
Metabolic.
Myxedema.
Porphyria.

Vogel et al.[12] specifically attempted to evaluate aldosterone responsiveness as reflected by urine aldosterone levels in a case demonstrating this syndrome, associated with a cerebral tumor. They found aldosterone levels to be within the normal range at all times and exhibiting a normal response pattern to changes in extracellular fluid volumes.

Very little is known regarding the pathophysiological relationships between these various diseases and this syndrome.

Two cases reported by Carter et al.,[8] both with central nervous system disease (one metastatic tumor and one skull fracture), seemed to exhibit a biphasic pattern. Early in the syndrome antidiuretic hormone secretion appeared to be independent of both extracellular fluid volume and tonicity, as evidenced by prompt excretion of a massive saline load which transiently raised extracellular fluid volume higher and sodium levels to normal. Later, antidiuretic hormone effect appeared less marked in response to volume expansion. This may represent decreased renal responsiveness to antidiuretic hormone as mentioned earlier rather than to actual suppression of antidiuretic hormone as they suggested.

Carter's group and others were able to demonstrate sodium retention in response to small doses of 9-alpha-fluorohydrocortisone. This ability in association with failure to retain a salt load and continued natruresis with a negative sodium balance was suggested as evidence in support of the concept of reduced aldosterone activity and also to confirm the preservation of renal-tubular salt-retaining ability.

This conflicts with the earlier opinion of Peters who, in 1950, presumed

Continued

the underlying mechanism to be renal salt-losing secondary to central nervous system disease, either directly via the renal nerves or indirectly by depressed adrenocorticotropic hormone.

Goldberg[9] felt that, while the exact mechanism of hyponatremia associated with inappropriate antidiuretic hormone is unknown, it may be due in part to two factors: a. Increased glomerular filtration rate, b. Decreased secretion of aldosterone, both directly or indirectly resultant from the increased extracellular volume.

As Leaf has pointed out[7] a small urine volume may not be present during all stages of the antidiuretic hormone syndrome because, after the initial stage of water retention, oliguria and natruresis, two conditions tend to modify continued antidiuresis: (a.) The glomerular filtration rate increases promoting water excretion, (b.) Renal tubular response to antidiuretic hormone is seemingly decreased.

It is observed that after the initial phase, urine volume will closely reflect water intake. This would appear to be a safety mechanism protecting these patients from unlimited over-expansion of body fluid volume.

A case exhibiting a prolonged tendency to inappropriately secreted antidiuretic hormone was reported by Epstein et al.[14] This patient had a persistently abnormal electroencephalogram thought to represent an abnormality of upper brain stem and diencephalon region, but no other neurological disease was evident. For a period of over two years she was managed satisfactorily with serum sodium in 140-145 mEq/L range by instructing her to drink only when thirsty. The inappropriate antidiuretic hormone syndrome was reproduced at intervals in this patient by administration of a water load.

In cases associated with myxedema, the syndrome could not be reproduced after the patient became euthyroid with treatment.[16]

The syndrome has been observed during acute exacerbations of porphyria, but in the interim between attacks, the syndrome could not be reproduced.[17]

Goldberg[9] has summarized some pathophysiologic situations which could be responsible for the inappropriateness of antidiuretic hormone control in this syndrome:

a. A persistent positive stimulus for antidiuretic hormone secretion, such as an irritative lesion within the central nervous system or persistent impulses from receptors within a diseased thorax.

b. Defective ability to maintain inhibition of antidiuretic hormone secretion in response to normal inhibitory stimuli.

c. Re-setting of osmoreceptors to a subnormal level.

d. The multiple possibilities associated with neoplasms.

Treatment

The most important facet of treatment is fluid restriction. In most patients studied, correction was approaching normal by about the third to the sixth day after institution of fluid restriction. Some authors[15] have mentioned supplementary use of mannitol, which increases free water excretion, but is of little consequence compared to fluid restriction. Alcohol was usually ineffective.

Long-term management largely depends on the underlying disease. Success will require a cooperative and intelligent patient.

Prognosis

This also depends on the associated disease process. Some patients reported never achieved fluid balance prior to death. A patient followed for over two years has been mentioned, in whom the antidiuretic hormone defect remains, and in whom the syndrome can be reproduced at will, yet who is subjectively well, providing fluid intake does not exceed that necessary to quench thirst.[14] Reference has been made to the findings in myxedema and porphyria during the treated and symptom-free intervals.

Case Report

An 81-year-old Caucasian male was admitted 1/23/66 to Hennepin County General Hospital in acute respiratory distress. Physical findings were those of chronic obstructive pulmonary disease with an acute exacerbation. There was a history of chronic lung disease for many years with frequent acute episodes, the last in September 1965. He also carried the diagnosis of chronic brain syndrome secondary to cerebral arteriosclerosis and had a diffusely abnormal EEG. with normal cerebral spinal fluid.

Initial treatment consisted of I.V. fluids, bronchodilators and IPPB. On the second hospital day he was felt to be in incipient cardiac failure and was given thiomerin and digitalized without observable change in clinical status. On the fourth hospital day he was found to weigh 166 pounds (15 pounds more than when last discharged), and to have a serum sodium of 122 mEq/L and a urine specific gravity of 1.031. There was no overt edema.

These findings were suggestive of inappropriate antidiuretic hormone syndrome. There was no significant response to infusion of 500 cc. of 5% alcohol, nor any striking response to a mannitol test dose.

Fluid restriction was instituted with subsequent weight loss, rise in serum sodium and modest improvement in overall clinical status. The subsequent hospital course was complicated by his underlying pulmonary disease and obstructive uropathy, but without overt evidence of further fluid and electrolyte imbalance. The patient was discharged from the hospital ambulatory and at his baseline chronic pulmonary and chronic brain syndrome status.

Adrenal function was not assessed. There was clinical evidence of mild congestive heart failure. Renal function was modestly impaired.

Well enough for old folks to rise early, because they have done so many mean things all their lives they can't sleep. — Mark Twain

It works.

*What's New in Hematology?**

ALBERT B. HAGEDORN, M.D.**
Rochester, Minnesota

SIGNIFICANT ADVANCES are being made in hematology — equally as impressive as those being made in other fields of medicine. This review will be confined to the clinical or practical advances† and will leave to others the experimental and research advances, which perhaps are more impressive.

Blood Transfusion

Hematologists have always held that many more transfusions of blood have been given than were actually required. This is serious because of the potential hazards associated with the administration of blood. In addition, blood is a precious commodity that must be conserved for therapeutic and economic reasons, research purposes, and national defense needs. We are now beginning to advocate administration of only the specific fraction of blood that is needed by the individual patient. As a result of the improvement and simplicity of the equipment for collecting and separating the component parts of blood, all blood banks can readily fractionate the whole blood obtained from donors. If there is a need for whole plasma, then this alone should be given; if there is a need for platelets, then only platelets should be given; if there is a need for antihemophilic globulin, then only a concentrate rich in this substance should be given; and, if there is anemia requiring transfusion, then only packed erythrocytes should be given. Recently, an analogy has been drawn between the old "shotgun" hematinic therapy and the giving of whole blood, the point being that only the substance lacking should be prescribed. Even infusions of granulocytes are being given in certain cases of leukopenic leukemia to tide the patient over an acute secondary infection or febrile episode. However, this still is not a general practice because it requires a sufficient pool of chronic granulocytic leukemic patients — to act as donors; and the separation of the leukocytes from the other cellular components presents complex technical problems. At the present time this type of transfusion can be done only in large research centers such as the National Institutes of Health.

A practical technique for harvesting antihemophilic globulin from whole plasma has been developed by Dr. Judy Pool at Stanford. It depends on the use of cold temperatures for precipitation of fibrinogen which is rich in factor VIII. Then, by plastic-bag technique, this protein can be removed and the rest of the plasma conserved. This cryoprecipitation of fibrinogen can also be used to concentrate antihemophilic globulin from outdated blood. It has been shown in our laboratory that so-called old blood in the

†I am indebted to Drs. Joseph M. Kiely and E. J. Walter Bowie for some of the ideas mentioned in the text.

Continued

blood bank still contains about 50% of the original antihemophilic globulin that was present when the blood was fresh. We now can make use of this antihemophilic globulin by separating it out by Pool's technique. Another new development is the use of animal antihemophilic globulin concentrates in treating patients with hemophilia and circulating anticoagulants. Most of this experience has been in Europe, but some trials have been made in this country.

Anemia

The reports of the past year indicate that androgen therapy is not as effective as previously suggested for the anemia occurring in the myeloid metaplasia of myelofibrosis and myelosclerosis. In my experience, testosterone has not helped in any such cases. However, in an occasional case of nonhemolytic anemia that may occur in lymphoproliferative syndromes such as chronic lymphocytic leukemia, testosterone has produced some impressive effects. Use of testosterone is also advocated in aplastic anemia, but most results have been poor. Use of testosterone, together with corticosteroids, is also currently advocated for prevention of marrow aplasia when toxic chemical agents are used therapeutically — for example, in conjunction with cyclophosphamide (Cytoxan) or L-sarcolysin (Alkeran) in the treatment of multiple myeloma. The long-acting testosterone derivative, testosterone enanthate (Delatestryl), is given intramuscularly once weekly in a dosage of 600 mg. Impressive remissions of multiple myeloma have occurred with a combined program of L-sarcolysin, prednisone, and testosterone.

Coagulation Defects

Within the past year a new coagulation factor has been officially accepted — factor XIII, the fibrin-stabilizing factor or the Laki-Lorand factor. The new coagulation disorder associated with deficiency of factor XIII has been seen in more than 10 cases. These cases are characterized by severe umbilical bleeding at birth, a condition apparently mistaken for one of the hemophilic states in the past. A case in an adult (31 years old) was also recently recognized. The condition is probably hereditary and occurs in both sexes. All the usual coagulation tests give normal results in these patients. A clot does form, but it is of poor quality. The deficiency is recognized by testing the clot with 5M urea or monochloroacetic acid; normal clots are insoluble in these solutions but, when factor XIII is deficient, the clot readily dissolves. A single transfusion of blood may be effective in preventing further bleeding for as long as two weeks.

The Fibrinolytic States

The dilemma of distinguishing the fibrinolytic states from the consumptive coagulopathies (a new term favored by the coagulationists) has not been solved. There is no single specific test that distinguishes between the two entities and, further complicating the picture, similar clinical conditions may trigger either mechanism. Various causes, such as malignant disease, sepsis, hemolytic transfusion reactions, obstetric complications, and certain pulmonary and pelvic operations, may initiate the production of either a fibrinolysin or a massive intravascular thrombosis or embolization with subsequent depression of many of the coagulation factors. The diagnosis may have to be intuitive. For the fibrinolytic state epsilon-aminocaproic acid (Amicar) is the drug of choice. For the consumptive coagulopathies (often called defibrination syndrome) heparin is the drug of choice. The dilemma is great. Although excellent concentrates of fibrinogen are readily available, administration of fibrinogen alone is not the treatment for some of the consumptive coagulopathies, for example, the one often seen by obstetricians. Because of the deficiencies of prothrombin, factor V, factor VIII, and platelets as well as of fibrinogen, it would be more reasonable to give whole, fresh blood carefully collected in plastic bags rather than fibrinogen alone as is sometimes done.

The Thrombocytopenic States

Thrombocytosis has now been recognized as an occasional complication of malignant disease and may be a worthwhile early clue, when no other signs of the malignant process are evident.

Likewise, thrombocytopenia may occasionally occur with malignant disease, but it is usually associated with what is now called "microangiopathic hemolytic anemia," which results from a variety of disease entities, all characterized by spastic small blood vessels. These changes in the blood vessels lead to changes in the erythrocytes and to anemia similar to the anemia seen after certain heart-valve operations. A clue is the morphologic change in the erythrocytes which are characterized by marked poikilocytosis with frequent schistocytes. This is seen in a variety of conditions, including malignant hypertension, thrombotic thrombocytopenic purpura, systemic lupus erythematosus, polyarteritis nodosa, and metastatic malignancy.

It is feasible to obtain reasonable platelet harvests from whole blood by use of plastic bags for transfusion to patients with thrombocytopenia. However, for the isoimmune thrombocytopenic purpuras with circulating antibodies, platelet transfusions obviously will be ineffective. Steroids are considered to be the drug of choice for acute idiopathic thrombocytopenic purpura (ITP). In chronic ITP, especially in adults, the risk of continued steroid therapy is greater than the risk of splenectomy. For the patient not responding to either steroids or splenectomy, an antimetabolite, such as 6-mercaptopurine or azathioprine (Imuran), can be used as an immunesuppressive agent.

Hematologic Reactions

Although it is well known that drugs are capable of producing adverse hematologic reactions, it is worth emphasizing the point that there is a potential new hazard to the blood with the introduction of each new drug or therapeutic preparation. Every physician should be aware of this potential hazard and should inform his colleagues whenever an unexpected response occurs in a patient.

The recent interest in recognizing the cellular reaction to chloramphenicol (Chloromycetin) bears no relationship to recognizing the adverse fatal reactions that sometimes occur. With the former, the vacuolation of the erythrocyte precursors noted in the bone marrow is directly related to the dose of chloramphenicol, can be predicted, and is reversible if the drug is discontinued in time. With the fatal aplastic anemias and pancytopenias which may occur from chloramphenicol, there seems to be a sensitivity

Continued

reaction involved; this cannot be predicted or prevented and is not related to dose. It probably is related to sensitization from previous use of the drug.

Megaloblastic Anemia

For many years it has been recognized that megaloblastic anemia occasionally develops secondary to anticonvulsant therapy. This results chiefly from diphenylhydantoin (Dilantin) and mephenytoin (Mesantoin), but other anticonvulsant drugs can do this, too. It is now realized that this is an induced folic-acid deficiency state and that patients who develop this anemia need not discontinue the anticonvulsant drug. A therapeutic dose of folic acid is given along with the anticonvulsant.

Hypersensitivity Reaction

In certain cases of chronic myelocytic leukemia treated with busulfan (Myeleran), an interstitial pulmonary fibrosis may develop which, if not recognized early, can lead to the death of the patient. The early signs are cough and wheezing, and a thoracic roentgenogram will show bilateral, fan-shaped pulmonary shadows. The mechanism of this phenomenon is not understood, but apparently it is a hypersensitivity reaction. If the busulfan therapy is stopped early enough, the condition will abate.

Drugs

A new use for an old drug is that of aminopyrine in the treatment of the debilitating febrile reactions that may occur in patients with lymphoma, especially Hodgkin's disease. This is used particularly in cases in which the bone marrow will not tolerate any more specific treatment and high fever persists. The new drug indomethacin (Indocin) is equally effective in this respect and may be the drug of choice.

Recently, 6-mercaptopurine has been shown to have a favorable effect in controlling Waldenström's hyperglobulinemic purpura. However, this is a relatively benign condition and I would think a woman would have to have a strong desire to be rid of her discolored legs before I would be willing to give her such a potentially toxic substance.

In Waldenström's macroglobulinemia, a malignant condition entirely different from the aforementioned state with the same eponym, chlorambucil (Leukeran) has proved to be very effective in controlling the signs and symptoms. Dr. Edwin Bayrd of the Mayo Clinic first used this in treating Waldenström's macroglobulinemia and has been successful in more than 25 cases. Plasmaphoresis has been effective in managing the distressful complications caused by the hyperviscosity syndrome that sometimes occurs in Waldenström's macroglobulinemia and less frequently in multiple myeloma. The condition can be verified by a simple laboratory test: measuring the serum viscosity index by means of a capillary viscometer. After the abnormal globulin has been removed from the plasma by differential centrifugation, the remaining plasma is returned to the patient along with the cellular elements of the blood.

A new chemotherapeutic agent has been added to the armamentarium for treatment of Hodgkin's disease. It is a methylhydrazine derivative marketed as Natulan: a cytotoxic agent whose exact mechanism of action is not known. It is of a different class than the other presently used agents and, therefore, can be given when these other agents have reached their limitations of clinical usefulness.

A new attitude toward Hodgkin's disease has developed recently. Efforts are being made to stage the disease accurately because many radiologists and hematologists think that stage I Hodgkin's disease is now potentially curable. Stage I Hodgkin's disease is defined as one in which the disease is limited to one anatomic region or to two contiguous anatomic regions on the same side of the diaphragm. Although clinical examination in cases of Hodgkin's disease is relatively simple and accurate, it often fails to reveal the status of the iliac and retroperitoneal regions. As a result, if a patient is considered to be probably in stage I, it is mandatory that a retroperitoneal lymphangiogram be made. With present methods this is a simple, low-risk procedure that can be done on an outpatient basis, with results available within 24 hours. If the retroperitoneal lymphangiogram is negative, then high-dose obliterative radiation is given to the localized peripheral nodes.

Diagnosis

Finally, a new, simple, rapid, and apparently reliable test for detecting heterophil antibodies of infectious mononucleosis in serum is now available. It depends on a commercial reagent developed by Wampole Laboratories (Stamford, Connecticut) and called the Mono-Test. Reports indicate an overall accuracy of 99% with no false-negative results noted. It takes only two minutes to perform and can be easily done in an office laboratory. The results so far reported suggest that its specificity may be sufficiently indicative of infectious mononucleosis to eliminate the need for titration and differential absorption tests.

Buckle Up*

Check Your Car

Many freeway accidents are caused by cars pulled off the road because of mechanical failure. If you plan to use a freeway on your next trip, prepare your car for continuous high speed driving conditions.

BEFORE YOU GO brakes, exhaust system, windshield wipers and lights should be operating properly. Tires should be in good condition and properly inflated for continuous high speed travel. Fill the fuel tank and check water, fan belt, oil and battery.

ON THE ROAD stop every two hours to have fuel, water, oil and tire condition checked. You will have to leave the freeway for these stops. Watch for signs indicating exits to service areas.

Learn what your gas gauge means. Know how much gas your tank holds when full, half full, etc. Know how many miles your car can go on a gallon of gas. Too many emergency stops on highways are due to running out of gas. Tire trouble is another of the most common causes.

Why do more Minnesota Doctors insure with The St. Paul?

Probably because our Professional Liability coverage is so thorough.

Really broad coverage. Fewer exclusions, so interpretations are no problem. The price is likely to be nice, too.

To get the folder that tells all about it concisely, write.

The St. Paul is the approved carrier for the State Medical Association here . . . and in more states than any other single insurance company. It must be something we offer!

Want to see just 1 insurance man and still be fully insured? Use our St. Paul Multicover Plan. Same agent as for Liability. He's in the Yellow Pages.

For further information, or the name of your nearest St. Paul agent, please contact the St. Paul office at:

St. Paul, 385 Washington Street 55102 **Phone: 221-7911**

SMALL BOWEL ULCERATION FROM THYAZID AND POTASSIUM THERAPY

This syndrome of ulceration of the small bowel has now occurred sufficiently often to be of clinical significance in a patient who is receiving Thyazid and potassium therapy for diuresis.

Enteric coating dissolves in approximately five hours and in the instance of enteric-coated potassium therapy with the release of high concentrations of potassium in the lower jejunum, it is reasonable to expect that this area of the small gut will be more frequently involved.

The Food and Drug Administration has requested all manufacturers of Thyazid and oral diuretics, as well as coated potassium salt preparations, to include a warning on the label of such products, suggesting that the drug be withdrawn if symptoms occur. It is recommended that coated potassium tablets should be used only when adequate dietary supplementation is not practical.

Carl O. Rice, M.D.
Minneapolis, Minnesota

THORACOTOMY FOR DIAGNOSIS

Exploration was carried out in 110 persons with obscure chest lesions, 78 of whom were tuberculin reactive. Fifty-six patients had symptoms and were X-rayed promptly. In one-half, unfortunately, 6 months elapsed before thoracotomy was undertaken. In forty instances, the X-ray revealed a coin lesion, and seven of these were found to be malignant. In the remaining 53 pulmonary cases, with X-ray appearance suggesting consolidation, atelectasis, cavity, and multiple nodulation, there were 21 with malignant disease. Definitive surgical treatment was carried out in 82 cases. The over-all operative mortality was 6.4%, but since 1960 it has been only 3.5%. There were no persistent complications in the survivors. Five patients who were found to have carcinoma are still alive, and in three of these the indication for operation was a coin lesion. Two of them had metastatic tumors and have a poor prognosis. "Watchful waiting" is very dangerous when dealing with an undiagnosed intrathoracic lesion. The low mortality and morbidity of exploratory thoracotomy justifies immediate exploration of such patients.

DECOMPRESSION OF CIRCUMFERENTIAL LIMB BURN

The accumulation of edema fluid in subcutaneous compartments of the burned limb may increase the tissue pressure sufficient to cause damage out of proportion to the burn.

The indications for decompressing the tissue with a longitudinal incision are that the burn is deep, that there is a progressive loss of sensation, and that the distal part of the extremity is cool. With these indications an emergency decompression may be indicated and could usually be performed in the ward without anesthesia. The importance of carrying the decompression incision to the deep fascia must be kept in mind. There may be some risks in doing this, e.g., production of an open wound, contamination, and systemic infection; but the advantages in properly indicated cases outweigh the disadvantages. When it is possible, this procedure should be carried out in the operating room under adequate anesthesia.

FORAMINOTOMY FOR HERNIATED LUMBAR DISC

Shenkin and Haft have used foraminotomy in conjunction with the removal of the herniated disc in 536 patients. They found that foraminotomy done initially facilitated the displacement of the nerve root and provided a better exposure of the disc. When necessary, they did not hesitate to remove the facet in order to obtain a satisfactory lateral exposure.

In the postoperative period early ambulation was practiced. In the followup series, in endeavoring to compare their results with others reported in the medical literature, their excellent and good results formed a significantly higher percentage than had previously been reported, so that they were able to classify 92 percent as falling in the excellent or good result category. The poor results were obtained in those patients who presented less obvious signs and symptoms than are usually evident when disc disease is present.

They preferred foraminotomy over spine fusion because it presented fewer morbidity figures and the healing period was considerably diminished from that evident in those patients who had undergone removal of the disc and spine fusion.

FROSTBITE IN CHILDREN

The effects of frostbite sustained in early childhood in 13 patients (seven adults and six children) are reported. The shortest interval between the frostbite and examination was four and one-half years, and the longest 50 years. Frostbite in a child may be severe enough to destroy the cartilage cells of the epiphysial plate of a digit and produce clinical deformity. The affected phalanges are short and smaller than normal; the juxta-articular bone is expanded and irregular with the spongiosa altered to show a coarse cancellous pattern; the same expanded and

SQUIBB NOTES ON THERAPY

"'Tranquilizer' is not a good word"[1]

"THIS classification is psychologically too seductive, pharmacologically too unspecific, and in terms of results not infrequently untrue."[2]

What is a tranquilizer? According to the 24th Edition of Dorland's Medical Dictionary[3] a tranquilizer is "an agent which acts on the emotional state, quieting or calming the patient without affecting clarity of consciousness."

Defining a drug by its effects, however, can be misleading. The same effects by which the dictionary defines a tranquilizer have sometimes been seen after administration of a sedative — or, for that matter, a placebo.

Ambiguous though the term may be, it appears to be here to stay. The 1966 edition of the Physicians' Desk Reference[4] lists 42 tranquilizers indicated for treatment of anxiety and apprehensive states.

'Tranquilizers' have differences in action, differences in effect

Although all tranquilizers are intended to calm anxious patients there *are* differences in their actions — and in their effects. They have been divided into three categories — the rauwolfia group, the 'minor' tranquilizers, and the phenothiazines.[5]

Although the tranquilizing effect of rauwolfia has been known for centuries, its use as an antipsychotic agent in current practice has diminished.[5]

A 'minor' tranquilizer is often prescribed to achieve more than one effect. Thus, besides being tranquilizers some of these compounds may be muscle relaxants, antihistaminics with some calming action, anticholinergic sedatives, or antispasmodics.[5]

The phenothiazines are considered 'major' tranquilizers because they alter psychotic behavior.[1] This classification may have done them more harm than good because it implies that the phenothiazines should be reserved for the more severely disturbed. This is not necessarily true.

The phenothiazines — and the problem of sedation

One of the problems of prescribing phenothiazines for ambulatory patients has been the fear that excessive sedation will impair the patient's ability to function. This, however, is less of a problem with some of the phenothiazines.

"Clinically they may be differentiated primarily in terms of their potency and the extent of their sedative effect, which appear to be inversely proportional. That is, the least potent, the one which is used in highest dosage, chlorpromazine, is the most sedative, while the reverse holds true for fluphenazine."[6]

In a recent report on various studies conducted over several years evaluating 360 patients treated for anxiety and stress with seven phenothiazines, this inverse relationship of potency to sedation was confirmed.[7] Also under consideration was the degree to which the particular phenothiazines neutralized anxiety (the angolytic index). Interestingly enough there was, again, an inverse relationship. The most sedative of the phenothiazines appeared to be the least active in neutralizing anxiety. Fluphenazine, one of the least sedative, on the other hand, was found to be most effective in relieving anxiety.[7]

RELATIVE SEDATIVE AND ANGOLYTIC INDICES OF PRINCIPAL PHENOTHIAZINES*

DRUG	SEDATIVE INDEX	ANGOLYTIC INDEX	BASED ON STANDARD DOSE OF
Chlorpromazine	100	15	25 mgs.
Triflupromazine	100	15	25 mgs.
Thioridazine	90	17	25 mgs.
Perphenazine	15	25	4 mgs.
Carphenazine	25	25	25 mgs.
Trifluoperazine	3.3	95	2.0 mgs.
Fluphenazine	3.5	100	2.5 mgs.

*adapted from Sainz[7]

Prolixin is therapeutically effective without excessive sedation

When used as a 'tranquilizer' in general medical practice, in many patients Prolixin (Squibb Fluphenazine Hydrochloride) suppresses anxiety, but not normal activity. These two features are of particular importance to patients who must be able to live and work without their normal daily activitie being restricted.

Because of its longer duration o action, Prolixin, in doses of as littl as one to three milligrams in adults, generally taken once a day, is effective in maintaining many patients free of their symptoms o anxiety and tension.

Contraindications: Do not use with high doses of hypnotics or in patients with subcortical brain damage. Use with caution in patients with a history of convulsive disorders. Severe reactions may occur in patients with idiosyncrasy to other centrally-acting drugs, and severe hypotension may occur in patients with special medical disorders, e.g. mitral insufficiency and pheochromocytoma.

Precautions: Effects of atropine, anesthetics and C.N.S. depressants may be potentiated. Hypotension may occur in patients undergoing surgery. Do not use epinephrine for treatment of the hypotensive reactions which may appear in patients on phenothiazine therapy.

Side Effects: Extrapyramidal reactions, allergic skin reactions, the possibility of anaphylaxis, drowsiness, visual blurring, dizziness, insomnia, nausea, anorexia, salivation, edema, perspiration, dry mouth, abnormal lactation, polyuria, hypotension and jaundice and biliary stasis may occur. Routin blood counts are recommended to determine possible blood dyscrasias; if symptoms of upper respiratory infection occur, discontinue drug an institute appropriate therapy.

Available: 1 mg. tablets. Bottles of 50 and 500.

PROLIXIN®

SQUIBB FLUPHENAZINE HYDROCHLORIDE

SQUIBB

'The Priceless Ingredient' of every produc is the honor and integrity of its maker.

irregular appearance is seen on the contiguous surface of the more proximal phalanx where there is no epiphysis. The joint surfaces are irregular and uneven, but the width of the joint space does not seem to be altered. Usually the epiphysis appears to have disappeared completely, but in some there is only partial destruction with the undestroyed portion remaining and taking part in the joint disfiguration. In the adult the roentgenographic changes are not so distinctive, and the joint changes cannot be differentiated from a long-standing polyarthritis. No clear-cut or significant abnormality of the vascular pattern is found. It is suggested that the deformities may be helped by interphalangeal fusion of severely involved joints in the position of function, and phalanges that become angled into varus or valgus may be improved by open wedge osteotomy or epiphysiodesis of the side of the functioning epiphysis.

INFECTION IN COLON SURGERY

At the University of Cincinnati, 90 patients undergoing elective colon operations were studied pertaining to infection of the wound or diarrhea. These patients were classified into five different groups depending on the preoperative and postoperative medication, which was designed to eliminate infection. It was observed that those who received no preoperative medication but were given Procaine penicillin G and tetracycline after operation had no postoperative wound infection or diarrhea, whereas in the other four groups in which antibiotic medication was given preoperatively and postoperatively the incidence of infection was higher.

They also observed that advanced age, extreme obesity, remote infection, prolonged operation and a protracted period of preoperative hospitalization were the greatest contributing factors in the development of wound infection or diarrhea.

They were able to conclude that the postoperative administration of penicillin and a broad-spectrum antibiotic seemed to be the best prophylactic combination for the prevention of infection following colon surgery.

BREATH HOLDING SEIZURES

Twenty children with severe breath holding episodes were studied to delineate the clinical and physiological features of a spell. A very consistent sequence was observed. Expiratory apnea of about 40 sec. occurred after provocation by a frustrating or painful stimulus. Opisthotonos and incontinence occurred at the end of the apnea and was followed by a variable period of stupor. Physiologically, the oximetry curve dropped to below 30% saturation while the pulse and blood pressure remained high. The electroencephalogram was of high voltage and low frequency. The postulated mechanism of the seizue is that of anoxic anoxia.

DISCREPANCY IN LEG LENGTH

Additional blood flow to a long bone is considered to be one of the more important factors for stimulating the growth of epiphysis in order to bring about a correction in the discrepancy of leg length. Procedures which have been designed to provide this additional stimulation have been periosteal stripping, implantation of foreign material, arterial venous anastomosis, and occlusion of the medullary cavity.

More recently, Dickerson has performed experiments in the growing puppy by transferring the femoral artery into the medullary cavity of the long bone, thereby providing increased arterial supply. As a control he used the opposite femur, performing the same operation except that he did not transfer the artery into the medullary cavity. In every instance in which an artery had been diverted, he found that the length of the bone was equal to or longer than the opposite femur of the same animal, with an increase in length extending up to two millimeters.

One might be dubious as to whether or not the "dummy operation" stopped the normal growth process. The benefit obtained from this type of procedure readily becomes obvious; but one might be more convinced if the period of observation had been extended two or three times as long.

TUMORS OF THE SMALL INTESTINE

Twenty-seven primary tumors of the small intestine, which were encountered at the University of Alberta Hospital in a 10-year period, have been reviewed. Seventeen symptomatic growths were treated by operation and ten asymptomatic tumors were discovered incidentally. During this same period, three intramesenteric lipomas were found. Small intestine tumors were malignant in 15 of the 17 symptomatic and benign in seven of the nine asymptomatic patients. Carcinoid tumors, malignant lymphomas, nonlymphoid sarcomas, and carcinomas were the common malignant neoplasms, whereas adenomas, lipomas, myomas, fibromas, and angiomas comprised the majority of benign growths reported. Symptoms of anorexia, anemia, abdominal pain, obstruction, and hemorrhage suggest small intestine tumor if more common pathology has been ruled out. The preoperative sedimentation rate in 8 patients with malignant lesions was over 20 mm/hour; in all 8, death or recurrence ensued within 2 years. Three patients with malignant growths and sedimentation rates under 10 mm/hour showed no recurrence within 3-8 years of resection. Case reports of calcified ileal carcinoid with massive calcified liver metastases and a leiomyoma (within a resected Meckel's diverticulum) which recurred as leiomyosarcoma are presented in detail.

Special Article

The Phonocardiogram in the Diagnosis of Heart Diseases*

HILTRUD MUELLER, M.D.**
JEROME T. GRISMER, M.D.†
Minneapolis, Minnesota

THE PURPOSE of this article is to define the relationship between the hemodynamics of the heart and the heart sounds in the normal heart and in certain common heart diseases. The article is not intended as a complete review of the subject of phonocardiography. Further, the accepted interpretation on controversial parts is presented, rather than a discussion of the controversial points. If the reader is interested in further information, he should refer to standard texts of phonocardiography. The relationship between the hemodynamics of the heart and the heart sounds are clarified by simultaneous registration of phonocardiogram, electrocardiogram and intercardiac pressures.

Heart Sounds

First Heart Sound (Figure 1)

The first and second heart sounds are predominantly valve closure noises. As the ventricular pressure exceeds the atrial pressure, the mitral and the tricuspid valves close. The sudden interruption of the blood flow from the atrium into the ventricle and the ventricular backflow against the valves institute vibrations of the valve leaflets. These vibrations produce the main part of the first heart sound. Before this main component there are some low frequency vibrations which occur after the onset of the QRS complex in the electrocardiogram. They are normally related to myocardial contraction, preceeding the closure of the atrioventricular valves. There is normally a slight asynchronism between the left and right ventricular contraction. The contraction begins earlier in the left ventricle with the result that the mitral valve closes slightly in advance of the tricuspid valve. Thus the mitral component of the first heart sound appears a

**Trainee, American College of Cardiology.

†Director, Cardio Pulmonary Department, Mount Sinai Hospital, Minneapolis, Minnesota.

little earlier than the tricuspid component.

After the isometric contraction the systolic ventricular pressure exceeds the diastolic pressure of the aorta and pulmonary artery and the arterial valves open. This valve opening is silent to auscultation and external phonocardiography. Intracardiac phonocardiography demonstrates low-pitched vibrations of small amplitude.[1]

Second Heart Sound

At the end of the ejection phase, as the ventricular pressure falls below the pressure in the aorta and pulmonary artery, the aortic and pulmonic valves close. There is again a sudden interruption of the blood flow and a local backflow against the semilunar valve leaflets which vibrate and result in the second heart sound. Normally the aortic valve closes earlier than the pulmonic valve. The difference is about 0.025 seconds.

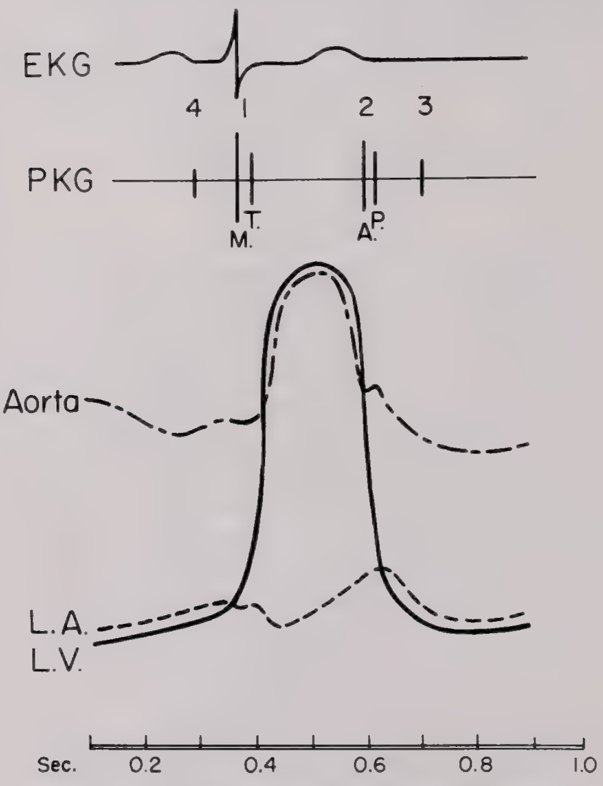

Fig. 1 — The relationship between electrocardiogram, heart sounds, and pressure curves of the left atrium (LA), left ventricle (LV) and aorta. (Drawing)

M = mitral valve component of first heart sound.[1]

T = tricuspid valve component of first heart sound.[1]

A = aortic valve component of second heart sound.[2]

P = pulmonic valve component of second heart sound.[2]

3 = third heart sound.

4 = fourth heart sound.

In the isometric relaxation phase the ventricular pressure drops below the atrial pressure, and the mitral and tricuspid valves open. This opening is silent in normal conditions, even with intracardiac phonocardiography, because flow occurs under a low-pressure condition. In abnormal states this valve opening becomes audible and delayed as in mitral and tricuspid valvular stenosis. This is the mitral or tricuspid "opening snap" heard on auscultation.

Third Heart Sound

The third heart sound is mainly related to vibrations of the ventricular myocardium from rapid filling in the early diastolic phase. The sound is usually physiological in young individuals. With aging, the occurrence of the third heart sound is pathological, "the protodiastolic gallop," a sign of decreased ventricular function. This sound is heard in lesions producing a diastolic overload of the ventricle, as in heart failure, aortic and mitral valvular insufficiency, or patent ductus arteriosus. The interval from the second to the third heart sound varies between 0.12 and 0.15 seconds.

Fourth Heart Sound

This sound is the result of atrial contraction. It occurs normally in children, and in an exaggerated form in adults as "the presystolic gallop," a result of elevated atrial pressure. This "presystolic gallop" is often auscultated in patients with a systolic overload of the ventricle (hypertension, coarctation of the aorta, aortic valvular stenosis, etc.).

A normal phonocardiogram of a 15-year-old healthy boy is reproduced in Figure 2. Depicted are the mitral and tricuspid components of the first heart sound and the aortic and pulmonic components of the second heart sound. The third sound of low frequency and small amplitude follows with an interval of 0.12 seconds. There is also a low-pitched fourth heart sound.

Pulmonary Hypertension

Normally, in young individuals, the aortic and pulmonic components of the second heart sound are of similar high amplitudes. With aging, the aortic component exceeds the pulmonic component, changes easily noted on clinical auscultation. In adults, a high amplitude of the pulmonic sound is a pathological sign of pulmonary hypertension from either primary lung diseases or lung changes secondary to cardiac malfunction. In cardiac lesions the principle functional effect for these lung changes is the obstruction to pulmonary venous flow. This is accompanied by pulmonary arteriolar vasoconstriction and medial hypertrophy, which is the basis for elevation of the pulmonary pressure above the level of the pulmonary capillaries and veins. Increasing medial hypertrophy and additional changes in the intima of the pulmonary arterioles increase the pulmonary hypertension. Mitral stenosis is a typical cause for these changes. They are less marked in mitral incompetence and are possible in all cardiovascular anomalies with a large left to right shunt.

Pulmonary Valvular Stenosis

In contrast to the high amplitude of the pulmonic component of the second sound in pulmonary hypertension, the amplitude is small in patients with diminished pressure and flow in the pulmonary artery, as in pulmonary valvular stenosis. In pulmonary valvular stenosis the interval between the aortic and the pulmonic component is increased ("split" as heard by auscultation) because of the delayed closure of the pulmonic valve secondary to the prolonged ejection time of the right ventricle. There is a relationship between the length of this "split interval," the severity of the stenosis, and the degree of the right ventricular hypertension.[2] The more severe the stenosis, the longer the "split interval." For example, a split-interval of 0.06 seconds indicates a pressure of approximately 100/mm/Hg in the right ventricle (the normal is 25-30/mm/Hg).

Right and Left Bundle Branch Block

Similarly, right bundle branch block produces a widely "split" second heart sound (Figure 3-a). In this case, the delay of the depolarization and the repolarization of the right ventricle results in a late closure of the tricuspid valve, producing splitting of the first heart sound.

Left bundle branch block can result in a paradoxic splitting of the second sound (Figure 3-b) in which the small pulmonic precedes the larger aortic component of the second sound. The delay in the activation of the left ventricle leads to a delayed closure of the aortic valve and to a delayed occurrence of the aortic component. This paradoxic splitting may disappear after deep inspiration. With inspiration the increased volume in the right ventricle prolongs its ejection time and delays the closure of the pulmonic

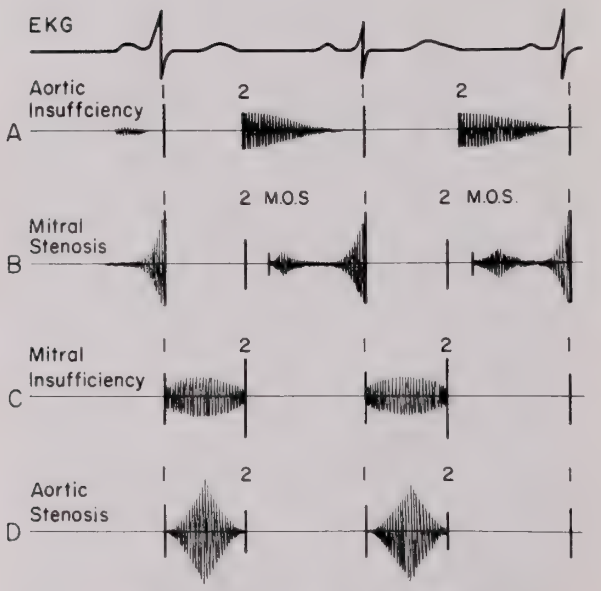

Fig. 4 — Characteristics of heart murmurs in valvular stenosis (ejection murmur) and insufficiency (regurgitation murmur).

valve. The result is that both components of the second sound come closer together or may appear at the same time.

Considering these hemodynamic changes, it is possible to diagnose a right bundle branch block or left bundle branch block by auscultation. In left bundle branch block the wide splitting of the second sound disappears after deep inspiration; in right bundle branch block, it remains unchanged.

Heart Sounds in Mitral Stenosis

By analysis of the phonocardiographic record, a reliable method is available to judge the severity of mitral valvular stenosis. Two points are important in this judgment:

The first is the interval between the second heart sound (II), and the mitral opening snap. As mentioned before, under normal conditions there is no noise in the opening of the mitral valve. In mitral stenosis the narrowed fibrotic valve "snaps" toward the ventricle in the early diastole when the elevated atrial pressure exceeds the diastolic ventricular pressure. The vibrations of the valve, due to this snapping, are one cause for the mitral opening snap: The time lapse between the second sound and the mitral opening snap is the mitral opening interval, which depends on the pressure gradient between the left atrium and the left ventricle. The higher the left atrial pressure, the greater the gradient, the earlier the valve snaps into the ventricle and the earlier, the mitral opening snap. Figure 3-c schematically shows the change of the mitral opening interval at different heart rates. Due to a faster heart rate and a decreased diastolic phase, the emptying of the left atrium is more difficult. Consequently the gradient between left atrial and left ventricle increases and the mitral opening interval increases.

"Snappy" sounds shortly after the second heart sound (possibly representing opening snaps of normal valves) occur in instances of very large diastolic flow across the atrioventricular valves. Examples are large atrial or/ventricular septal defect or patent ductus Botalli.

NE OF THE ROBITUSSIN® FORMULAS

nant mitral valvular stenosis,[5] a relationship was noted between the second heart sound mitral opening snap interval, the mean pulmonary artery wedge pressure, the mean pulmonary artery pressure, and the opening orifice of the mitral valve (Table 1). The less the time of the second sound interval, the higher the mean pulmonary artery wedge pressure, the higher the pulmonary artery pressure, and the smaller the orifice of the mitral valve. The normal valve opening varies between 4 cm^2 and 6 cm^2.

In patients with mitral valvular stenosis, there is also a relationship between the II - mitral opening snap interval and the functional classification by the New York Heart Association (Table 1).

a. Functional classification I - No symptoms at rest - Mitral opening interval of 0.09 sec. or more.

b. Functional classification II - Symptoms at rest - Mitral opening snap of 0.09-0.07 sec.

c. Functional classification III - Right heart failure which disappears after treatment - Mitral opening interval of 0.07-0.055 sec.

d. Functional classification IV - Right heart failure despite treatment - Mitral opening interval less than 0.055 sec.

A second point which is helpful in estimating the severity of mitral stenosis is the delay of the first heart sound. The normal interval between the onset of the QRS complex and the first heart sound ranges between 0.03 and 0.05 seconds. If the atrial pressure is high, the ventricular pressure curve requires a longer time to exceed the atrial pressure. Consequently, the mitral valve closure and the occurrence of the first heart sound (I) are delayed. In a series of 120 patients with predominant mitral stenosis of functional class II-IV,[2] this interval was abnormally prolonged (average 0.07 seconds). Successful corrective valve surgery on the mitral valve restored the interval to normal with the exception of five patients.

Heart Murmurs

The following are examples of the difference in the characteristics of the systolic heart murmurs in valvular stenosis (ejection murmur) and valvular insufficiency (regurgitation murmur) as recorded on the phonocardiogram.

Valvular Stenosis

In aortic and pulmonic valvular stenosis the typical diamond-shaped systolic ejection murmur appears (Figure 4-d). There is a relationship between the severity of the stenosis and the onset and the peak of the murmur. The more severe the stenosis, the later is the beginning as well as the maximum amount of blood ejected through the narrowed valve and the later is the onset and peak of the murmur.

Systolic Murmur

The systolic murmur in mitral or tricuspid valvular insufficiency (Figure 4-c) differs from the systolic murmur of semilunar valvular stenosis. It occurs immediately after the first heart sound with the beginning of the isometric contraction phase. Usually the amplitude of the vibrations do not change markedly and the murmur appears as a band on the phonocardiographic tracing. Sometimes the murmur has a slight crescendo-decrescendo form. In tricuspid insufficiency, the amplitude of the vibrations temporarily increases after inspiration because of the increased blood volume of the right heart.

Diastolic Murmur

Diastolic heart murmurs also have certain identifying characteristics. The diastolic

TABLE I
Mitral Stenosis

*mean pressure

Continued

murmur of aortic insufficiency is a high frequency decrescendo murmur appearing immediately after aortic component of the second heart sound (Figure 4-a). The diastolic murmur of mitral stenosis begins only after the mitral opening snap, which marks the moment of maximum tension of the left atrial wall and the narrowed mitral valve. At this time the atrial pressure exceeds the ventricular pressure and the blood flow starts. The murmur is low-pitched, and in sinus rhythm it shows a presystolic crescendo during atrial contraction (Figure 4b).

Conclusion

Phonocardiography is helpful in the diagnosis of heart diseases. By this graphic method, accurate correlation can be made with the various heart sounds and murmurs, the sequence of electrical excitation and the auscultatory findings. This information is not only useful in diagnosis but important in the evaluation of treatment and prognosis of patients with heart diseases.

The Tobacco Tyrant*

Bishop relates: "Young people have a peculiar susceptibility to tobacco, and they suffer from its direct effect upon the heart. Tobacco makes the susceptible heart irritable, irregular, and intermittent. Part of this effect is probably due to vascular disturbance. On general principles, a cigar is the least harmful form of smoking. A pipe is stronger, and cigarets are particularly harmful on account of the incomplete combustion and the frequency with which they are used."

Faught declares: "Nicotin is, next to adrenalin, the most powerful vaso-constrictor known. Tobacco, in the form of pipe, cigar, and cigaret, has the power of raising blood pressure. Arterial disease tends to augment the effect of smoking on arterial pressure. In cases of anginoid attacks, tobacco in all forms should be prohibited entirely."

Blumgarten says: "Nicotine is one of the most violent poisons known. Chronic tobacco poisoning follows excessive smoking. The patient usually complains of palpitation of the heart, has a rapid, irregular pulse, is very nervous, and may have digestive disturbances."

Charles Lyman Greene, in his book on Examination For Life Insurance, has this to say: "It is very evident that the excessive use of tobacco is productive of disease. The most injurious form is undoubtedly the excessive smoking of cigarets. In elderly men, the over-use of tobacco is a positive danger by reason of its toxic effect upon the heart."

1

Contraindications: Thrombophlebitis or pulmonary embolism (current or past). Existing evidence does not support a causal relationship between use of Norinyl and development of thromboembolism. While a study which was conducted does not resolve definitively the possible etiologic relationship between progestational agents and intravascular clotting, it tends to confirm the findings of the Ad Hoc Advisory Committee appointed by the Food and Drug Administration to review this possibility. Cardiac, renal or hepatic dysfunction. Carcinoma of the breast or genital tract. Patients with a history of psychic depression should be carefully studied and the drug discontinued if depression recurs to marked degree. Patients with a history of cerebral vascular accident.

Warning: Discontinue medication pending examination if there is sudden partial or complete loss of vision, or if there is a sudden onset of proptosis, diplopia or migraine. If examination reveals papilledema or retinal vascular lesions, medication should be withdrawn.

Precautions: By May 1963, experience with norethindrone 2 mg.—mestranol 0.1 mg. had extended over 24 months. Through miscalculation, omission or error in taking the recommended dosage of Norinyl, pregnancy may result. If regular menses fail to appear and treatment schedule has not been adhered to, or if patient misses two menstrual periods, possibility of pregnancy should be resolved before resuming Norinyl. If pregnancy is established, Norinyl should be discontinued during period of gestation since virilization of the female fetus has been reported with oral use of progestational agents or estrogen. When lactation is desired, withhold Norinyl until nursing needs are established. Existing uterine fibroids may increase in size. In metabolic or endocrine disorders, careful clinical preevaluation is indicated. A few patients without evidence of hyperthyroidism had elevated serum protein-bound iodine levels, which in the light of present knowledge, does not necessarily imply hyperthyroidism. Protein-bound iodine increased following estrogen administration. Bromsulphalein retention has occurred in up to 25% of patients without evidence of hepatic dysfunction. Studies from 24-hour urine collections have shown an increase in aldosterone and 17-ketosteroids and decrease in 17-hydroxycorticoid levels. Thus, Norinyl should be discontinued prior to and during thyroid, liver or adrenal function tests. Because progestational agents may cause fluid retention, conditions such as epilepsy, migraine and asthma require careful observation. Thus far no deleterious effect on pituitary, ovarian or adrenal function has been noted; however, long-range possible effect on these and other organs must await more prolonged observation. Norinyl should be used with caution in patients with bone, renal or any disease involving calcium or phosphorus metabolism.

Side Effects: Intermenstrual bleeding; amenorrhea; symptoms resembling early pregnancy, such as nausea, breast engorgement or enlargement, chloasma and minor degree of fluid retention (if these should occur and patient has not strictly adhered to medication plan, she should be tested for pregnancy); weight gain; subjective complaints such as headache, dizziness, nervousness, irritability; in a few patients libido was increased. In a total of 3,090 patients, 2.2% discontinued medication because of nausea.

NOTE: See sections on contraindications and precautions for possible side effects on other organ systems.

Dosage and Administration: One Norinyl tablet orally for 20 days, commencing on day 5 through and including day 24 of the menstrual cycle. (Day 1 is the first day of menstrual bleeding.)

Availability: Dispensers of 20 and 60 tablets; bottles of 100.

BE A MYTH-MONGER #6

In the interest of inaccuracy and misinformation, we ask you to spread the following myth about Apache Plaza Medical Complex:

DOCTORS DON'T WANT FULL APPOINTMENT SCHEDULES

But let's face it, Doctor, that's what makes a successful practice. If you're looking for more names in that appointment book, it's imperative that you consider Apache Plaza Medical Complex for your office location. It's in the heart of an already large residential area that is also the fastest growing area in the Twin Cities, with top incomes and young, growing families possessing superb credit. It's a natural if it's success you're after.

Book Reviews

If a man empties his purse into his head, no man can take it away from him. An investment in knowledge always pays the best interest. — Franklin

OPERABLE HEART DISEASE — PATHOPHYSIOLOGY, DIAGNOSIS, AND TREATMENT — **Howard D. Sirak, M.D. C. V. Mosby Company, 1966, 130 Pages, $12.50.**

The key to this book's objectives is found in the Foreword (R. H. Wylie) and the Preface (H. W. Sirak). "A guide to understanding the basic problems" — "should be received gratefully by the student - by the surgical intern - physicians who must understand circulatory dynamics in their day to day management."

The text succinctly discusses terminology, routine and special diagnostic techniques, and fetal circulation and physiology. The basic concepts of the heart lung machines, the changes in open-heart surgery, and the postoperative care are summarized. The common congenital and acquired cardiac lesions are diagramatically illustrated, the abnormal physiology noted and the surgical correction discussed.

Comment: The author has presented concepts adequately although briefly. The numerous diagrams are excellent and undoubtedly contribute to the cost. There are no other illustrations such as electrocardiographs or physiological graphs. A bibliography is not included. Not only would this be an excellent text for students, but would also be a fine text for the paramedical groups such as technicians, nurses, and medical secretaries.

Jerome Grismer, M.D.

RESUSCITATION OF THE NEWBORN INFANT AND RELATED EMERGENCY PROCEDURES — PRINCIPLES AND PRACTICE — 2nd Edition. The C. V. Mosby Co., St. Louis. Publication date: June 7, 1966, $16.50.

Few books deserve to be recommended as required reading. This book is one. All persons who assist the birth of infants or who supervise their first breaths should read this book. The compelling reasons for seeking more knowledge to promote neonatal survival are known to all who supervise those exciting moments, fraught with hope for life, but tinged with the chance of death.

This is not a book to be bought and not read — it is one to be read and re-read and thumbed through until clinical observations and research progress make it obsolete and a new edition appears.

CONTROVERSY IN INTERNAL MEDICINE — **Edited by Franz J. Ingelfinger, Arhold S. Relman, and Maxwell Finland, W. B. Saunders Company, Philadelphia and London. 679 pages, $14.50.**

In this delightful book, 74 authorities square off in 23 chapters for the intellectual championships of internal medicine. The protagonists, who vary from two to five in a single chapter, are well matched in their academic credentials. All have been superbly conditioned in preliminary bouts in the medical journals, and most are regarded as the reigning champions of their concept of the disease in question.

The chief judges are Franz Ingelfinger, Arnold Relman, and Maxwell Finland — veterans of the academic arena in Boston. They pick the sites of verbal conflict, the sizes of the canvas, and — in closely contested encounters — they join the melee as combatants. In the program are such heavyweight debates as arteriosclerosis and diet, the use of hypertensive drugs, the dilemmas of anticoagulants, the management of gastric and duodenal ulcers, the malignant potential of colonic polyps, the causes of hemochromatosis, and the vagaries of statistics.

The controversies include only those subjects in which conclusive evidence for pathogenesis and management is lacking. The discussants feint, spar, and counter with all the weapons in their verbal arsenal — their experience, the deficiencies in their opponent's data or logic, numerical manipulation, and references to Shakespeare, the Bible, and George Washington. In some essays solid blows are exchanged, and the judges award a decision; other discussions end as draws and offer an artful exercise in shadow boxing. The judges' wordings in their decisions are pungent and pithy and, in my opinion, their comments alone are worth the price of admission.

vignettes of angina pectoris — no. 1 in a series:

angina and the surgeon

John Hunter —
British surgeon (1728-1793)

angina of anger

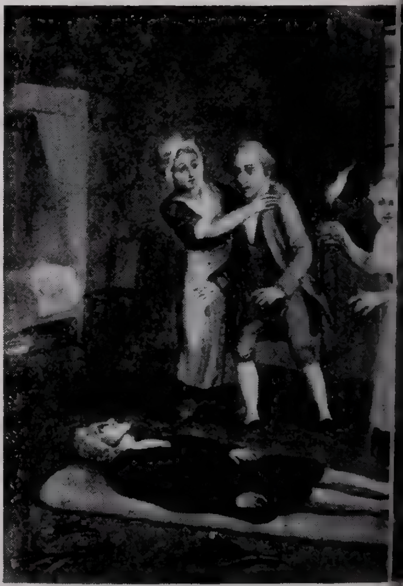
"My life is in the hands of any rascal who chooses to annoy and tease me."[1] So said the great British surgeon and anatomist, John Hunter, realizing that he could not control the anger which precipitated frequent and severe attacks of angina pectoris. According to Mettler: "His statement was no exaggeration. On October 16, 1793, he attended a meeting of the St. George's hospital staff, and, while defending the interests of several students, he was contradicted and thoroughly antagonized. The pains of angina commenced, he started toward another room, gained it, and fell dying into the arms of a physician."[2]

Why Edward Jenner withheld his paper on angina In 1777, at an earlier stage of the condition, Hunter's angina alarmed a favorite pupil, Edward Jenner, who wrote to Dr. Heberden that he feared his teacher was "affected with symptoms of the Angina Pectoris."[3] So concerned was Jenner about his former teacher's emotion-related condition that he deliberately cancelled publication of a paper on angina pectoris, fearing that Hunter would read it, and have "his fears excited by its truly formidable nature."[4]

Severity of angina described Hunter's brother-in-law, Dr. Everard Home, who witnessed his death and performed an autopsy, gave this account of the later stag of the condition:

"... the pain became excruciating at the apex of the heart; the throa was so sore as not to allow of an attempt to swallow anything and the left arm could not bear to be touched....

"The affections above described were, in the beginning, readily brought on by exercise ... but the at last seized him when lying in bed, and in his sleep...."[5]



18th century ancestor of the modern coronary candidate Surgeon, anatomist, pathologist physiologist, geologist, and teach Hunter had a passion for researc which led him to disregard his practice, his health and even the

in the modern management of angina pectoris

Peritrate® SA

Sustained Action (pentaerythritol tetranitrate) 80 mg.

Each double-layer, biconvex, dark green/light green tablet of Peritrate SA Sustained Action contains:
pentaerythritol tetranitrate .... 80 mg.
(20 mg. in immediate release layer and 60 mg. in sustained release base)

Peritrate (pentaerythritol tetranitrate) is a nitric acid ester of a tetrahydric alcohol (pentaerythritol).

Actions: The exact cause of angina pectoris (that is, the pain associated with coronary artery disease) remains obscure, despite the numerous and often conflicting hypotheses concerning its pathophysiology. Therapy at the present time, therefore, remains essentially empiric. Customarily, clinical improvement has been measured by: reduction in (1) number, intensity and duration of angina pectoris attacks and (2) necessity for glyceryl trinitrate intake for prevention or relief of anginal attacks.

Peritrate SA Sustained Action (pentaerythritol tetranitrate) 80 mg. has been reported in clinical usage to reduce in number and severity the incidence of angina pectoris attacks, with concomitant reduction in glyceryl trinitrate intake.

In the evaluation of Peritrate (pentaerythritol tetranitrate) and Peritrate SA Sustained Action (pentaerythritol tetranitrate) 80 mg. in angina pectoris, clinical improvement has been customarily measured subjectively by reduction in number and severity of attacks and necessity for glyceryl trinitrate intake for prevention or abortion of anginal attacks. Individual patterns of angina pectoris differ widely as does the symptomatic response to antianginal agents such as pentaerythritol tetranitrate. The published literature contains both favorable and unfavorable clinical reports. In conjunction with total management of the patient with angina pectoris, Peritrate (pentaerythritol tetranitrate) and Peritrate SA Sustained Action (pentaerythritol tetranitrate) 80 mg. have been accepted as safe for prolonged administration and widely regarded as useful.

Animal pharmacology: In a series of carefully designed studies in pigs, Peritrate (pentaerythritol tetranitrate) was administered for 48 hours before an artificially induced occlusion of a major artery and for seven days thereafter. The pigs were sacrificed at various intervals for periods up to six weeks. The result showed a significantly larger number of survivors in the drug-treated group. Damage to myocardial tissue in the drug-treated survivors was less extensive than in the untreated group. Pigs rather than dogs were used because their coronary artery distribution more closely resembles that of human beings. Studies in dogs subject to oligemic shock through progressive bleeding have demonstrated that Peritrate (pentaerythritol tetranitrate) is vasoactive at the postarteriolar level, producing increased blood flow and better tissue perfusion. These animal experiments cannot be translated to human behavior

Indications: Peritrate SA Sustained Action (pentaerythritol tetranitrate) 80 mg. is indicated for the relief of angina pectoris (pain associated with coronary artery disease). It is not intended to abort the acute anginal episode but is widely regarded as useful in the prophylactic treatment of angina pectoris.

Contraindications: Peritrate SA Sustained Action (pentaerythritol tetranitrate) 80 mg. is contraindicated in patients who have a history of sensitivity to the drug.

Warning: Data supporting the use of Peritrate (pentaerythritol tetranitrate) during the early days of the acute phase of myocardial infarction (the period during which clinical and laboratory findings are unstable) are insufficient to establish safety.

Precautions: Should be used with caution in patients who have glaucoma.

Adverse reactions: Side effects reported to date have been predominantly related to headache (which may require discontinuation of medication) and gastrointestinal distress which are usually transient with continuation of medication.

Dosage: Peritrate SA Sustained Action (pentaerythritol tetranitrate) 80 mg., 1 tablet immediately on arising and 1 tablet 12 hours later (on an empty stomach).

Additional dosage forms
Peritrate (pentaerythritol tetranitrate)—10 mg. and 20 mg. tablets with or without phenobarbital.

Peritrate with Phenobarbital SA Sustained Action — 80 mg. pentaerythritol tetranitrate and 45 mg. phenobarbital.

(**Warning:** Tablets containing phenobarbital may be habit forming.)

now...introducing a new high-strength dosage for

SIGNEM

A 'MAXIMUM SECURITY' ANTIBIOTIC*

- * THE BROAD RANGE DEPENDABILITY OF TETRACYCLINE
  long established as the broad-spectrum agent of first choice in a wide variety of infections
- * WITH THE ADDED SECURITY OF MEDIUM-SPECTRUM REINFORCEMENT
  triacetyloleandomycin is highly active against the common 'coccal' pathogens, including certain strains of staphylococci resistant to penicillin and tetracycline
- * ESPECIALLY VALUABLE IN U.R.I.
  provides decisive therapy in acute respiratory infections and other conditions in which staphylococci, streptococci or mixed flora are frequently encountered
- * NOW AVAILABLE IN NEW STRENGTH FOR NEW CONVENIENCE AND ECONOMY
  Signemycin 375—high-potency capsules for simpler administration, greater patient economy

YCIN® 375

(tetracycline 250 mg.
triacetyloleandomycin 125 mg.)

Indications: Indicated in the therapy of acute severe infections caused by susceptible organisms and primarily by bacteria more sensitive to the combination than to either component alone. In any infection in which the patient can be expected to respond to a single antibiotic, the combination is not recommended. Signemycin should not be used where a bacteriologically more effective or less toxic agent is available. *Triacetyloleandomycin, a constituent of Signemycin, has been associated with deleterious changes in liver function.* See precautions and adverse reactions.
Contraindications: Contraindicated in individuals who have shown hypersensitivity to any of its components. Not recommended for prophylaxis or in the management of infectious processes which may require more than 10 days of continuous therapy. If clinical judgement dictates therapy for longer periods, serial monitoring of liver function is recommended. Not recommended for subjects who have shown abnormal liver function tests, or hepatotoxic reactions to triacetyloleandomycin.
Precautions and Adverse Reactions: Triacetyloleandomycin, administered to adults in daily oral doses of 1.0 gm. for 10 or more days, may produce hepatic dysfunction and jaundice. Adults requiring 3 gm. of Signemycin initially should have liver function followed carefully and the dosage should be reduced as promptly as possible to the usual recommended range of 1.0 to 2.0 gm. per day. Present clinical experience indicates that the observed changes in liver function are reversible after discontinuation of the drug.
Use with caution in lower than usual doses in cases with renal impairment to avoid accumulation of tetracycline and possible liver toxicity. If therapy is prolonged under such circumstances, tetracycline serum levels may be advisable. In long term therapy or with intensive treatment or in known or suspected renal dysfunction, periodic laboratory evaluation of the hematopoietic, renal and hepatic systems should be done. Formation of an apparently harmless calcium complex with tetracycline in any bone forming tissue may occur. Use of tetracycline during tooth development (3rd trimester of pregnancy, infancy and early childhood) may cause discoloration of the teeth. Reversible increased intracranial pressure due to an unknown mechanism has been observed occasionally in infants receiving tetracycline. Glossitis, stomatitis, proctitis, nausea, diarrhea, vaginitis and definite allergic reactions occur rarely. Severe anaphylactoid reactions have been reported as due to triacetyloleandomycin. Photosensitivity and photoallergic reactions (due to the tetracycline) occur rarely. Medication should be discontinued when evidence of significant adverse side effects or reaction is present. Patients should be carefully observed for evidence of overgrowth of nonsusceptible organisms including fungi, which occurs occasionally, and which indicates this drug should be discontinued and appropriate therapy instituted. Steps should be taken to avoid masking syphilis when treating gonorrhea.

MOLECULAR REMODELING–

laboratory exercise or clinical necessity?

More than twenty-five years have passed since the discovery of the diuretic activity of sulfanilamide started pharmacologists on a succession of molecular remodelings to find the ideal diuretic.

Diuresis–a sought-after clinical effect from an unwanted side effect

It started in 1937 when a clinician reported that the administration of a sulfonamide was sometimes accompanied by an unexplainable side effect–metabolic acidosis.[1] Three years later the side effect was explained. The sulfonamide radical of sulfanilamide inhibited carbonic anhydrase,[2] the enzyme responsible for converting carbon dioxide and water to hydrogen ions and bicarbonate ions.

Later, other investigators showed by dog experiments that metabolic acidosis probably resulted when the inhibition of carbonic anhydrase upset the exchange of hydrogen and sodium ions, causing increased excretion of sodium as the bicarbonate.[3]

It was twelve long years after the first report of the unexplainable side effect (metabolic acidosis) that it was finally shown that large doses of sulfanilamide administered to edematous patients were indeed capable of promoting diuresis.[4] However, the possibility of toxic effects from its prolonged use and its relatively weak diuretic action made it impractical for clinical use as a diuretic.[5]

Because the inhibition of carbonic anhydrase seemed to be the key to effective diuresis, investigators began to look for more potent enzyme inhibitors —in the hopes that they would be more effective diuretics.

The most important of these early compounds, acetazolamide, enjoyed several years of fairly wide clinical use.

Its carbonic anhydrase inhibitory activity was several hundred times greater than that of sulfanilamide.[6] The increase in inhibitory activity, however, increased not only the excretion of sodium and bicarbonate ions, but also the excretion of potassium.[7] And, like its predecessor, acetazolamide precipitated mild acidosis. Its prolonged use could result in hypokalemic acidosis.[7]

The 'thiazides'–an answer to the metabolic acidosis caused by carbonic anhydrase inhibition

Despite the fact that the sulfonamide group appeared to be responsible for carbonic anhydrase inhibition which in turn appeared to be responsible for diuresis, investigators began to synthesize compounds with structural alterations to the sulfonamide group.

The first major breakthrough came with the synthesis of chlorothiazide. Altering the sulfonamide group did indeed alter the ability of chlorothiazide to inhibit carbonic anhydrase–it was only 1/10th as potent as acetazolamide in inhibiting the enzyme.[8] Despite the drop in inhibitory potency, however, chlorothiazide proved to be an effective diuretic–an observation that led to the conclusion that its diuretic action was due to some mechanism other than its action on carbonic anhydrase.[9,10]

For effective diuresis, chlorothiazide was administered in daily dosages ranging from 250 to 2000 mg.[11] It increased the excretion of sodium and chloride; and, to a lesser extent, potassium and bicarbonate.[11] The excretion of potassium appeared to be maximal at higher dose levels at which, theoretically, the carbonic anhydrase inhibitory effect is more active.[11] Its prolonged use, therefore, could sometimes result in metabolic hypokalemic, hypochloremic alkalosis.[7]

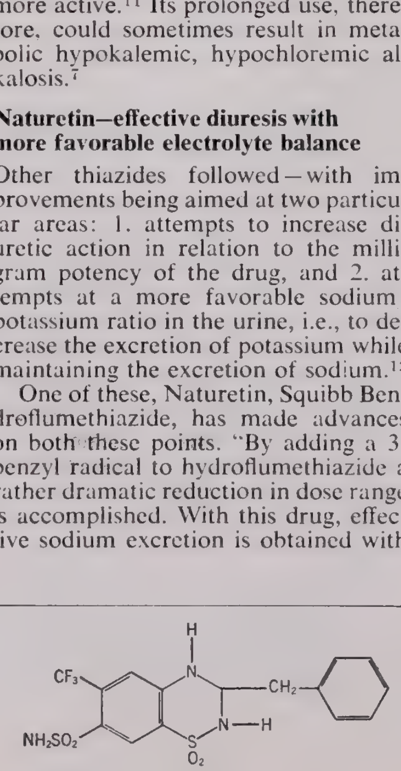
Naturetin–effective diuresis with more favorable electrolyte balance

Other thiazides followed—with improvements being aimed at two particular areas: 1. attempts to increase diuretic action in relation to the milligram potency of the drug, and 2. attempts at a more favorable sodium/potassium ratio in the urine, i.e., to decrease the excretion of potassium while maintaining the excretion of sodium.[12]

One of these, Naturetin, Squibb Bendroflumethiazide, has made advances on both these points. "By adding a 3-benzyl radical to hydroflumethiazide a rather dramatic reduction in dose range is accomplished. With this drug, effective sodium excretion is obtained with doses between 2.5 and 10 mg., which is a 200 to 1 ratio as compared to chlorothiazide..."[13]

Moreover, due probably to its virtual lack of carbonic anhydrase inhibition, Naturetin (bendroflumethiazide) has been shown to cause less potassium and bicarbonate loss and less alteration in urinary pH than either chlorothiazide or hydrochlorothiazide.

Naturetin is outstandingly effective not only in establishing, but also in maintaining, excretion of retained fluid in edematous patients. And its duration of action is sufficiently prolonged to allow a single daily administration in most patients. Naturetin is also an effective antihypertensive agent.



Contraindications: Severe renal impairment; previous hypersensitivity.

Warning: Ulcerative small bowel lesions have occurred with potassium-containing thiazide preparations or with enteric-coated potassium salts supplementally. Stop medication if abdominal pain, distension, nausea, vomiting, or G.I. bleeding occur.

Precautions: The dosage of ganglionic blocking agents, veratrum, or hydralazine when used concomitantly must be reduced by at least 50% to avoid orthostatic hypotension. Electrolyte disturbances are possible in cirrhotic or digitalized patients.

Side Effects: Bendroflumethiazide may cause increases in serum uric acid, unmask diabetes, increase glycemia and glycosuria in diabetic patients and may cause hypochloremic alkalosis, hypokalemia; cramps, pruritus, paresthesias, and rashes may occur.

Supplied: Naturetin (Squibb Bendroflumethiazide) 5 mg. and 2.5 mg. tablets. Also availabl Naturetin c̄ K [Squibb Bendroflumethiazid (5 or 2.5 mg.) with Potassium Chloride (50 mg.)]. For full information, see Product Brief

Medical Economics

U. S. Savings Bonds — A Good Investment!

One of the more pleasing features of our booming economy for the man who has money to save has been the escalating trend of interest rates the past few years. In fact, we live in an era of savage competition for the savings dollar. All over the nation financial institutions are bombarding us around the clock with newspaper, radio and television advertising announcing interest rates of 5, 5¼ and 5½ per cent in efforts to attract the savings dollar.

But few, if any, of the financial institutions advertising their high rates mention the income tax angle. Yet what matters particularly to long-term savers (including doctors) is not just the obvious interest rate but the net return after income taxes. Doctors have income tax problems, of course, perhaps more so than most people, and I am sure they are interested in a savings program designed to yield the highest rate of return.

The Series E Savings Bond pays 4.15 per cent when held to maturity (seven years), which on the surface, at least, does not appear to be at all competitive with other forms of savings. However, the key factor involved here is that you can defer payment of the Federal income tax due on your accumulated E Bond interest until you actually cash your bonds. You could wipe out your entire income tax liability if you don't start redeeming your E Bonds until you retire and move into an income range which may exempt you completely from paying income taxes. U. S. Savings Bonds are also exempt from state or local taxes, which further adds to the E Bond as a saving instrument deserving your attention.

How much do you really know about the attractive features of U. S. Savings Bonds? Here are some pertinent facts:

1. Savings Bonds are "indestructible." If lost, stolen, mutilated, or destroyed, the Treasury Department will replace them without charge.
2. Every $3.00 invested in Series E Bonds return $4.00 at maturity. The interest rate is guaranteed.
3. E Bonds may be redeemed for full purchase price, plus accumulated interest, any time after the first two months.
4. All E Bonds carry an optional 10-year extension privilege beyond maturity, continuing to earn interest, compounded semi-annually.
5. Savings Bonds are exempt from state and local income taxes, and the federal tax on E Bonds interest may be deferred until the bonds are redeemed.
6. E Bonds may be exchanged (in units of $500 or more, cash value) for Series H Bonds, which pay interest by Treasury check each six months. While the H Bond interest is taxable, tax on the accrued interest on E Bonds exchanged may continue to be deferred until the H Bonds are redeemed. This exchange may be made at any time, but is especially timely when you reach retirement and want extra income.
7. Savings Bonds may be registered in one

Continued

name alone, in two names as co-owners, or in beneficiary form. The surviving co-owner or beneficiary becomes sole and absolute owner upon death of owner.

The annual individual limitation on E Bonds has been raised to $20,000 (cash value $15,000). This limitation can be readily circumvented, however, by naming the wife or child as owner with the husband as co-owner or beneficiary on a bond; thereby, a family of four, for instance, could actually purchase $80,000 worth of E Bonds ($60,000 purchase price) annually.

We are not criticizing any of the many types of investments and savings available to the doctor or any other American. We *are saying* that the well balanced investment portfolio should include United States Savings Bonds.

It can be obviously seen from the table below that the United States Series E Savings Bond has a distinct net-yield advantage for the long-term saver or investor.

It is for this reason that we recommend that doctors take a good look at the Series E Bond when planning their financial portfolios and/or their retirement programs.

The following table, amended to include the state income tax exemption (prepared by Internal Revenue), dramatizes the value of tax deferral for a husband and wife filing a joint federal return. Find your own tax bracket, then look at the right-hand column showing the rate your investment would have to earn to be even with the E Bond rate plus its tax deferral feature.

Andrew J. Henjum*
St. Paul, Minnesota

Net Taxable Income	Because of State Income Tax-Exemption your 4.15% is equal to:	Your 4.15% with Tax Deferral is equal to:	Because of Total Tax Saving your 4.15% is equal to:
$ 3,000	4.37%	5.00%	5.26%
4,000	4.42%	5.12%	5.45%
8,000	4.51%	5.32%	5.78%

Society for Cryo-Ophthalmology

The Society for Cryo-ophthalmology has been formed to promote investigative and clinical applications of low-temperature technics to the eye. Applications for membership will be welcomed from those interested in the investigative aspects of this subject, the preservation of ocular tissue, therapeutic applications of cryogenics to various ocular diseases, and cryosurgical technics. It is contemplated that scientific meetings will be held immediately prior to the annual sessions of the American Academy of Ophthalmology and Otolaryngology.

Inquiries and applications should be addressed to Dr. John G. Bellows, 30 N. Michigan Blvd., Chicago, 60602.

Minnesota State Board of Medical Examiners

The Minnesota State Board of Medical Examiners and the State Examining Committee for Physical Therapists have announced that persons desiring to take the examination for registration of physical therapists must be graduates of a school of physical therapy approved by the Board for training physical therapists, in addition to the other statutory qualifications. Persons interested in determining their eligibility to take the examination for registration in physical therapy are advised to contact the Board in order to insure that the school they propose to attend is one approved by the Board.

Many overweight patients can benefit from the appetite control provided by the sustained anorexigenic-tranquilizing action of BAMADEX SEQUELS: anorexigenic action of amphetamine; tranquilizing action of meprobamate; prolonged action through sustained release of active ingredients.

Bamadex® Sequels®

DEXTRO-AMPHETAMINE SULFATE (15 mg.) WITH MEPROBAMATE (300 mg.) SUSTAINED RELEASE CAPSULES

to help establish a new dietary pattern

Contraindications: Dextro-amphetamine sulfate: in hyperexcitability and in agitated prepsychotic states. Previous allergic or idiosyncratic reactions to meprobamate.

Precautions: Use with caution in patients hypersensitive to sympathomimetic compounds, who have coronary or cardiovascular disease, or are severely hypertensive.

Dextro-amphetamine sulfate: Excessive use by unstable individuals may result in psychological dependence.

Meprobamate: Careful supervision of dose and amounts prescribed is advised, especially for patients with known propensity for taking excessive quantities of drugs. Excessive and prolonged use in susceptible persons, e.g. alcoholics, former addicts, and other severe psychoneurotics, has been reported to result in dependence on the drug. Where excessive dosage has continued for weeks or months, reduce dosage gradually. Sudden withdrawal may precipitate recurrence of preexisting symptoms such as anxiety, anorexia, or insomnia; or withdrawal reactions such as vomiting, ataxia, tremors, muscle twitching and, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, reduce dosage and avoid operation of motor vehicles, machinery or other activity requiring alertness. Effects of excessive alcohol consumption may be increased by meprobamate. Appropriate caution is recommended with patients prone to excessive drinking. In patients prone to both petit and grand mal epilepsy meprobamate may precipitate grand mal attacks. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side Effects: Overstimulation of the central nervous system, jitteriness and insomnia or drowsiness.

Dextro-amphetamine sulfate: Insomnia, excitability, and increased motor activity are common and ordinarily mild side effects. Confusion, anxiety, aggressiveness, increased libido, and hallucinations have also been observed, especially in mentally ill patients. Rebound fatigue and depression may follow central stimulation. Other effects may include dry mouth, anorexia, nausea, vomiting, diarrhea, and increased cardiovascular reactivity.

Meprobamate: Drowsiness may occur and can be associated with ataxia; the symptom can usually be controlled by decreasing the dose, or by concomitant administration of central stimulants. Allergic or idiosyncratic reactions: maculopapular rash, acute nonthrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever, transient leukopenia. A case of fatal bullous dermatitis, following administration of meprobamate and prednisolone, has been reported. Hypersensitivity has produced fever, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, stomatitis, proctitis (1 case), anaphylaxis, agranulocytosis and thrombocytopenic purpura, and a fatal instance of aplastic anemia, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity, usually after excessive dosage. Impairment of visual accommodation. Massive overdosage may produce drowsiness lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

The discomforts of

DIARRHEA
MUCOUS COLITIS
DIVERTICULITIS
SPASTIC URETERITIS
BLADDER SPASM

are relieved by direct musculotropic action with.....

Trocinate®

BRAND THIPHENAMIL HCl

Available in 100 milligram pink sugar-coated tablets.

The high therapeutic index permits dosage sufficient to relieve spasm promptly.

Administer 4 tablets every 4 hours until relief is constant, then adjust maintenance dosage.

Trocinate *BRAND* THIPHENAMIL HCl

Directly relaxes smooth muscle spasm
Combats hypermotility
Non-mydriatic, may be used in glaucoma

Sixteen years of clinical use, with absence of untoward effects, has established the safety and effectiveness of Trocinate.

Trocinate is metabolized in the body and completely eliminated, which is a safety factor. Dosage must be sufficient to maintain the therapeutic blood level.

● IMPORTANT! ●
CONVENTION
REGISTRATION FORMS

AMA '66
LAS VEGAS

POSTGRADUATE COURSES EXTRAORDINAIRES!

The 20th AMA Clinical Convention in Las Vegas, November 27-30, will offer three important Postgraduate Courses on topics of vital interest to the practicing physician . . . Fluid and Electrolyte Balance, Obstetrics and Gynecology, and Cardiovascular Disease. Eminent specialists in their fields will participate in programs to be given in three half-day sessions in the Las Vegas Convention Center.

Registration for each of these sessions is limited . . . be sure you don't miss out on the program of your choice by using the form below to register in advance. Because of the space limitation, please include a $10 registration fee for each postgraduate course you select.

DETAILS OF THE SESSIONS:

OBSTETRICS AND GYNECOLOGY

Monday thru Wednesday, Nov. 28-30, 9 a.m.-12 noon
Course Director and Moderator:
  Daniel G. Morton, M.D.
  Professor and Chairman, Dept. OB-GYN
  UCLA
Including 30-minute presentations on:
  Management of Septic-Abortion
  Intrauterine Transfusion for Erythroblastosis Fetalis
  Hypertensive Disorders in Pregnancies
  Human Sterilization: Indications, Legal Implications, Methods
Each presentation will be followed by a 10-min. discussion period.

CARDIOVASCULAR DISEASE

Monday thru Wednesday, Nov. 28-30, 2-5 p.m.
Course Director:
  George C. Griffith, M.D.
  Emeritus Professor of Medicine
  University of Southern California, Los Angeles
Recent Advances in Operable Cardiovascular Disease
Pulmonary Embolism: Prevention, Recognition, Treatment
Regional Arteriosclerosis
Each half-day session will be followed by a 30-minute panel discussion by all participants.

FLUID AND ELECTROLYTE BALANCE

Monday thru Wednesday, Nov. 28-30, 9 a.m.-12 noon
Course Director:
  Telfer B. Reynolds, M.D.
  Professor of Medicine
  University of Southern California School of Medicine
30-minute presentations on:
  Basic Concepts in Fluid and Electrolyte Balance
  Dehydration and Uremia
  Hyponatremia
  Hypokalemia and Hyparkalemia
  Normal Acid-Base Balance
  Acidosis and Alkalosis
Each morning's program will feature a 90-minute panel discussion.

FOUR EXCEPTIONAL BREAKFAST ROUND TABLE DISCUSSIONS

Tuesday, Nov. 29, 7-8:30 a.m.
1. "The Management of Metabolic Bone Diseases"
2. "Indication for Cardioversion"

Wednesday, Nov. 30, 7-8:30 a.m.
3. "The Problems and Potential of L.S.D."
4. "An Agonizing Reappraisal of Cancer Chemotherapy"

The price of each breakfast will be $3.00. Indicate your choice on the coupon below and include payment.

FOR RENT: Space available for surgical sub-specialists. Excellent location. Near Unity Hospital, 10 minutes from Mercy. Share space with General & Thoracic Surgeon and 2 interns. Call Mrs. Winkel — 560-1700, Fridley.

GENERAL SURGEON — Board certified experienced, all phases surgery and general practice. Prefer Twin Cities area. Write: MINNESOTA MEDICINE-367, 496 Lowry Medical Arts Bldg., St. Paul, 55102.

WANTED: Young general practitioner to join five-man group consisting of three GPs, a general surgeon, and radiologist. College town serving population of 22,000 30 miles from Twin Cities. Also need LOCUM TENENS in general practice. Contact: Ed Jenkins, Manager, River Falls Medical Clinic, River Falls, Wisconsin, Phone 425-5322.

PSYCHIATRIST (or interest in psychiatry) and general physician. 1,300 bed NP hospital with progressive treatment, full supporting staff. Community of 35,000 in hunting and fishing area, three colleges, 1½ hours from University of Minnesota. Salary range $15,000-$20,000 depending on qualifications. Liberal fringe benefits. Financial assistance in moving. License in one of the States, United States, required. Nondiscrimination in employment. Write Chief-of-Saff, VA Hospital, St. Cloud, MN 56301.

PATHOLOGIST — certified by American Board of Pathology. Desires location in the Twin Cities area, large or small hospital. Four years experience. All openings considered. Write MINNESOTA MEDICINE-366, 496 Lowry Medical Arts Bldg., St. Paul 55102.

GENERAL PRACTITIONER WANTED: to associate with Physician-Surgeon in Owatonna, a Southern Minnesota community, 25,000 population. Clinic building three years old; with five large treatment rooms; lab.; x-ray; central supply; two doctors' offices; pharmacy; and business offices. Located next door to 85 bed City Hospital. Good opportunity for partnership. Contact: O. W. Roberts, M.D.; 920 South Cedar St., Owatonna, Phone 451-4630.

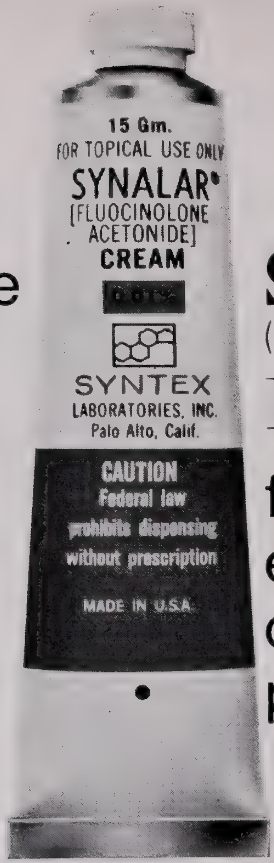
WANTED: young internist and pediatrician, board certified or eligible, to join five-man group consisting of three GPs, a general surgeon and a radiologist. College town serving population of 22,000 thirty miles from Twin Cities. Salary open with early partnership opportunity. Write or call collect: Ed Jenkins, Manager, River Falls Medical Clinic, River Falls, Wisc. Phone 425-5322.

WANTED: General surgeon, qualified or certified. Six man group in Minnesota. Fully accredited 150 bed hospital, open staff. Further information available. Write: Falls-Starekow Clinic, Thief River Falls, Minnesota. 56701.

GENERAL PRACTITIONER experienced in general medicine and surgery seeking location in Minneapolis area, independent or partnership. Write: MINNESOTA MEDICINE-368, 496 Lowry Medical Arts Bldg., St. Paul 55102.

WANTED: Locum tenens for large general practice St. Paul, Minnesota for February 1967. Salary open. Write: MINNESOTA MEDICINE-369, 496 Lowry Medical Arts Building, St. Paul 55102.

No matter how noble the objectives of a government, if it blurs decency and kindness, cheapens human life, and breeds ill will and suspicion — it is an evil government. — Hoffer.



new small size

Synalar® 0.01

(fluocinolone acetonide) **cream**

15 Gm.

for even greater economy in office or hospital practice

the superiority topical with the

Now you can prescribe as little or as much Synalar Cream 0.01% as is needed for a particular therapeutic problem in a size that permits the greatest economy for your patient. The new 15 Gm. tube, for example, is best suited for short-term therapy and for small sites. For more extensive body areas prescribe the 45 Gm. tube—a size that's also ideal for your treatment table. And the 120 Gm. jar is most economical for hospital use. Thus, with Synalar Cream 0.01%, you have the superiority of a modern topical corticosteroid shown to be more effective than 1% hydrocortisone[1-3] plus the economy that makes therapy practical for use in more dermatologic conditions, in long-term maintenance, with occlusive dressings in resistant cases, and in extensive area involvement.

Contraindications: Tuberculous, fungal, and most viral lesions of the skin (including herpes simplex, vaccinia, and varicella). Not for ophthalmic use. Contraindicated in individuals with a history of hypersensitivity to any of its components. **Precautions:** 1. *General*—Synalar Cream 0.01% is virtually nonsensitizing and nonirritating. Where severe local infection or systemic infection exists, the use of systemic antibiotics should be considered, based on susceptibility testing. While topical steroids have not been reported to have an adverse effect on pregnancy, the safety of their use on pregnan females has not absolutely been established. Therefore, they should not b used extensively on pregnant patients, in large amounts, or for prolonge periods of time. 2. *Occlusive dressing method*—With occlusion of extensiv areas, systemic absorption of the corticosteroid may occur, and suitabl precautions should be taken. Occasional patients may show contact sens tivity to a particular dressing material or adhesive. Miliaria, folliculitis, o pyodermas have been seen infrequently with the use of this technique. Th development of infection requires appropriate antibacterial therapy and di continuation of the occlusive dressing method. Local atrophy and stria have been reported with protracted occlusive dressing therapy. While lesio relapses can be expected to occur in many psoriatic patients, remission may persist for several weeks to several months in favorable cases. Th patient whose psoriasis is in an active stage, with recent appearance of ne lesions, may not be a good candidate and may show early relapse. Som plastic films may be flammable, and due care should be exercised in the use. Similarly, caution should be employed when such films are used on o left near children to avoid the possibility of accidental suffocation. **Sid Effects:** Side effects are not ordinarily encountered with topically applie corticosteroids. As with all drugs, however, a few patients may react unf vorably to Synalar under certain conditions. **References:** 1. Cahn, M. M., an Levy, E. J.: J New Drugs 1:262 (Nov.-Dec.) 1961. 2. Meenan, F. Sustained circulatory, respirator
and cerebral stimulation for th

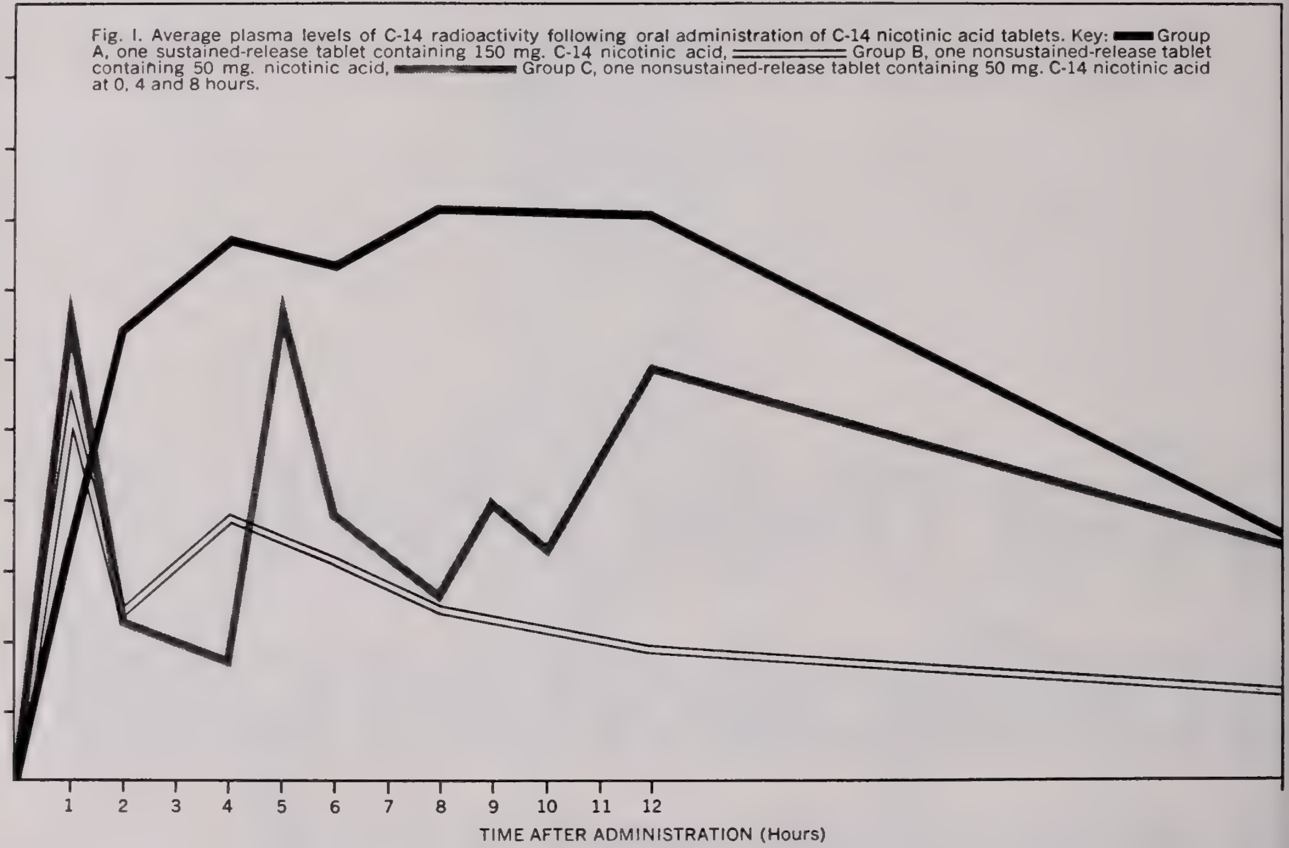

Fig. I. Average plasma levels of C-14 radioactivity following oral administration of C-14 nicotinic acid tablets. Key: ▬ Group A, one sustained-release tablet containing 150 mg. C-14 nicotinic acid, ═ Group B, one nonsustained-release tablet containing 50 mg. nicotinic acid, ▬ Group C, one nonsustained-release tablet containing 50 mg. C-14 nicotinic acid at 0, 4 and 8 hours.

(fewer absent doses by absent-minded patients)

Human volunteer subjects were administered Geroniazol TT tablets with the nicotinic acid component made radioactive with C-14. Plasma and urine samples were analyzed. (See Figures I and II) The radioactive tracer study substantiated the previous clinical evidence that the release of nicotinic acid from the Geroniazol TT tablet produced a gradual rise in plasma levels to a plateau for a total of 12 hours and more.

Such proven sustained activity makes the management of geriatric patients much easier by minimizing the possibility of neglected doses through absent-mindedness or senile confusion. Therapy *can* be continuous on a daily dose of only one Geroniazol TT tablet every 12 hours.

The gradual release of nicotinic acid in Geroniazol TT will provide the well-known peripheral vasodilatation needed in patients with deficient circulation and with a minimum amount (if any) of "flushing." Also, cerebrovascular circulation is complemented by pentylenetetrazol, long-established as a cerebral and respiratory stimulant.

Geroniazol TT improves the typical, unfortunate, signs of senile confusion. Patients become more alert,

ged and debilitated

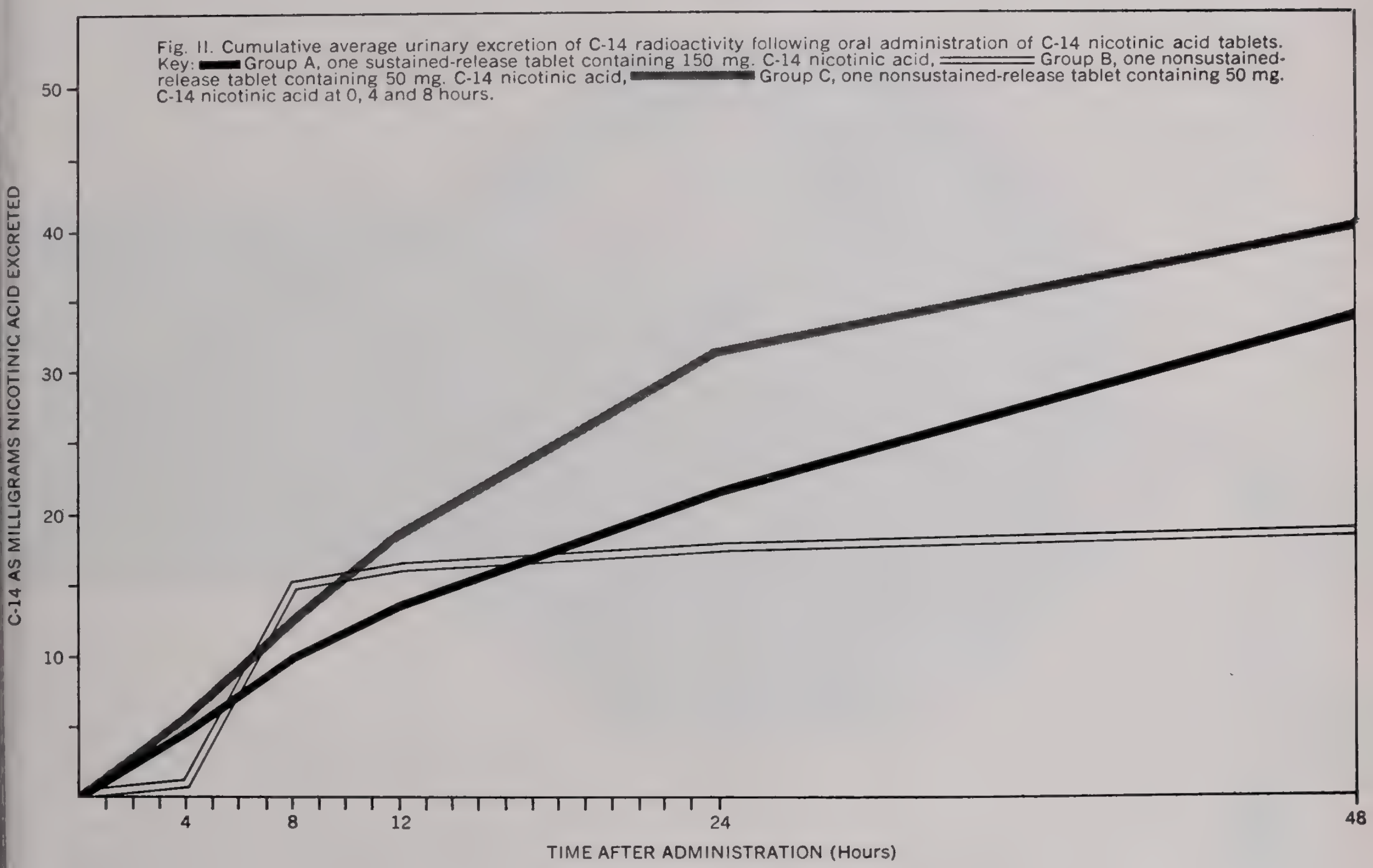

Fig. II. Cumulative average urinary excretion of C-14 radioactivity following oral administration of C-14 nicotinic acid tablets. Key: ▬ Group A, one sustained-release tablet containing 150 mg. C-14 nicotinic acid, ═ Group B, one nonsustained-release tablet containing 50 mg. C-14 nicotinic acid, ▬ Group C, one nonsustained-release tablet containing 50 mg. C-14 nicotinic acid at 0, 4 and 8 hours.

less confused and moody. Personal care, memory, emotional stability, social attention improve. Fatigue, apathy and irritability are reduced.

A prescription for 100 tablets of Geroniazol TT will permit your patients to enjoy the benefits of time-prolonged nicotinic acid/pentylenetetrazol therapy, at an economical price. Dosage is only one tablet every 12 hours.

Contraindications: There are no known contraindications.

Precautions: Exercise caution when treating patients with a low convulsive threshold.

Side Effects: Side effects are rarely encountered, however due to the vasodilatation effect of nicotinic acid, transitory mild nausea, flushing, tingling and pruritus are possible.

Dosage: One tablet every 12 hours.

Supplied: Prescribe bottles of 100 tablets, to take advantage of recent price reduction.

Geroniazol® TT

nicotinic acid 150 mg., pentylenetetrazol 300 mg.
Tempotrol® Time Controlled Tablet

When uncontrolled diarrhea brings a call for help

When the diarrhea sufferer has run the gam home remedies without success, pleasant-ta CREMOMYCIN can answer the call for help. It ca counted on to consolidate fluid stools, soothe i tinal inflammation, inhibit enteric pathogens, detoxify putrefactive materials — usually with few hours.

CREMOMYCIN combines the bacteriostatic ag succinylsulfathiazole and neomycin, with the sorbent and protective demulcents, kaolin and tin, for comprehensive control of diarrhea.

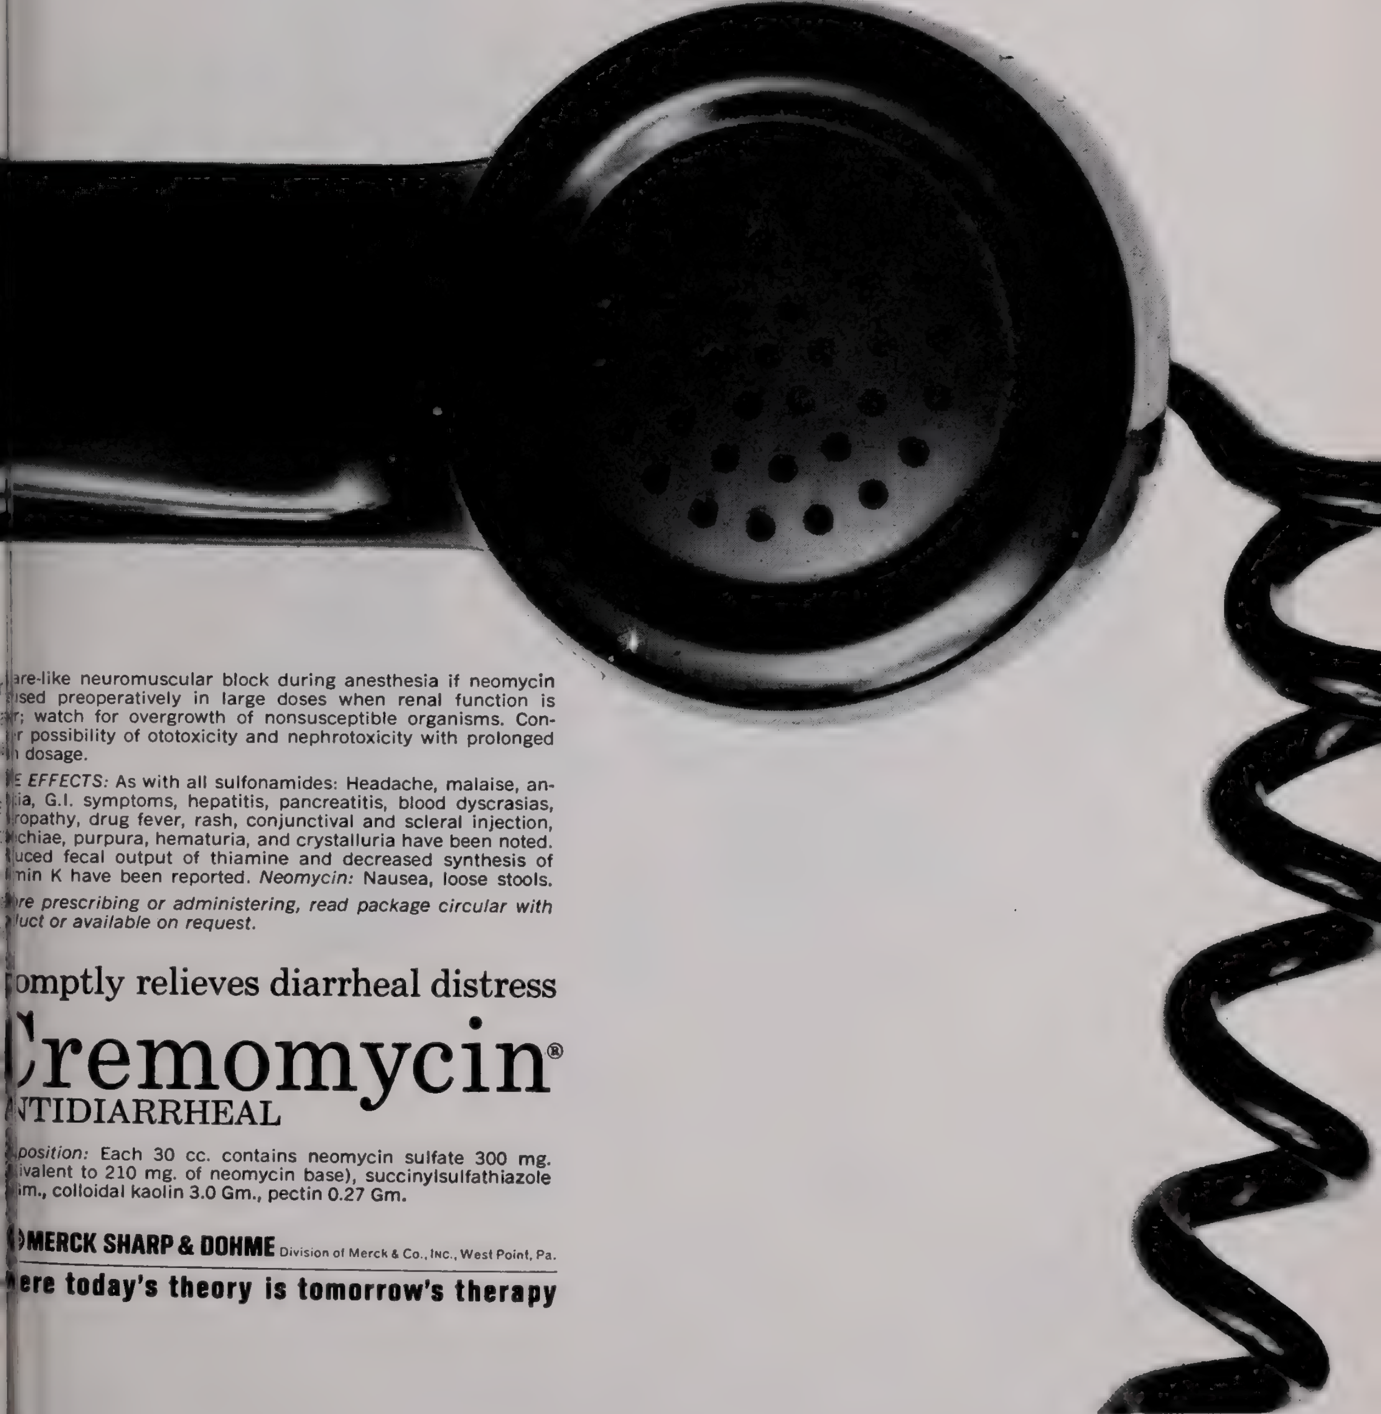
INDICATIONS: Diarrhea.

CONTRAINDICATIONS: Do not use in intestinal obstructic tensive ulceration of bowel, or diverticulosis; in hypersen to sulfonamides or neomycin; in pregnancy at term, in pren infants, or during first week of life in the newborn.

WARNINGS: Use only after critical appraisal in patient hepatic or renal damage, urinary obstruction, or blood c sias. Fatal hypersensitivity reactions and blood dyscrasi ported with use of sulfonamides. Consider periodic blood c hepatic and renal function tests during intermittent or c use.

PRECAUTIONS: Succinylsulfathiazole: Use with caution if is history of significant allergies and/or asthma. Continu requires supplementary vitamins B_1 and K. *Neomycin:* Wa

your ℞ for Cremomycin can provide relief



are-like neuromuscular block during anesthesia if neomycin ised preoperatively in large doses when renal function is r; watch for overgrowth of nonsusceptible organisms. Con- r possibility of ototoxicity and nephrotoxicity with prolonged dosage.

E EFFECTS: As with all sulfonamides: Headache, malaise, an- ia, G.I. symptoms, hepatitis, pancreatitis, blood dyscrasias, ropathy, drug fever, rash, conjunctival and scleral injection, chiae, purpura, hematuria, and crystalluria have been noted. uced fecal output of thiamine and decreased synthesis of min K have been reported. *Neomycin:* Nausea, loose stools.

re prescribing or administering, read package circular with luct or available on request.

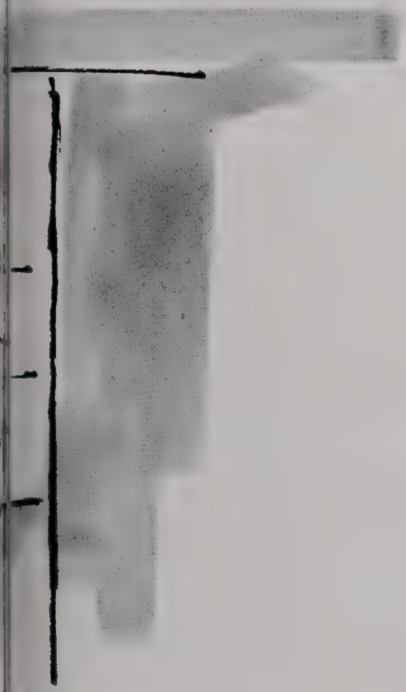
MERCK SHARP & DOHME Division of Merck & Co., INC., West Point, Pa.

ere today's theory is tomorrow's therapy



Wait, Annabelle. Mommy hasn't told the doctor yet that you *need* a shot.

e she does, maybe she
't. But if her problem is
congestion due to cold
ergy, consider the medi-
that combines conve-
e and effectiveness—
histine Melet.

et is especially suitable
treatment of children. It's
asant tasting, chewable
that leaves no aftertaste
tty, undissolved particles
in the mouth. It provides decongestant action almost as quickly as a liquid, but assures the accurate dosage of a tablet.

Because Melets are so convenient to carry and so easy to take at any time, adults, too, will appreciate this modern dosage form.

Use cautiously in individuals with severe hypertension, diabetes mellitus, hyperthyroidism or urinary retention. Caution adults who operate machinery or motor vehicles that drowsiness may occur. Each Melet contains phenylephrine hydrochloride 10 mg. and chlorpheniramine maleate 2 mg.

NOVAHISTINE® MELET

DOW **PITMAN-MOORE** Division of The Dow Chemical Company, Indianapolis

against the usual gram-negative urinary pathogens

Why use five...where **one** will do?

In a recent 217-patient hospital study,[1] urinary tract infections were treated with a variety of widely prescribed antimicrobial agents including: a sulfonamide (40 patients), chloramphenicol (20 patients), nitrofurantoin (33 patients), nalidixic acid (30 patients), tetracycline (27 patients), colistimethate sodium (22 patients)... and 2 combinations of 5 agents each (45 patients). The 2 combinations were selected to afford maximal theoretical antibacterial coverage against the usual urinary pathogens. They were (1) tetracycline, chloramphenicol, nitrofurantoin, ristocetin and polymyxin B; and (2) tetracycline, chloramphenicol, erythromycin, nitrofurantoin and colistimethate sodium.

This clinical study shows that the two combinations of antibiotics were not superior to some of their single components. The authors point out that antibiotic antagonism often negates theoretical advantages of multiple therapy. Coly-Mycin Injectable (colistimethate sodium) was one of the single components that was shown to be equal to the combinations and eradicated bacteriuria in two-thirds of the patients.

Theoretical choice of multiple antibacterial therapy has been shown to be no more effective than one well-chosen agent which also offers least patient exposure to possible side reactions, toxicities, allergic manifestations and higher drug costs.

1. McCabe, W. R., and Jackson, G. G.: New England J. Med. 272:1037, 1965.

in gram-negative urinary tract infections often the single well-chosen agent

COLY-MYCIN®
INJECTABLE

Coly-Mycin® Injectable

(colistimethate sodium)

Indications: Especially indicated for the treatment of severe acute and resistant chronic urinary tract infections due to sensitive strains of gram-negative organisms. Also indicated in respiratory tract, surgical, wound and burn infections and in septicemia due to sensitive organisms. Particularly indicated when any of these infections are caused by sensitive strains of *Pseudomonas aeruginosa.*

Adverse Reactions: Occasional reactions such as circumoral paresthesias, tingling of the extremities, pruritus, vertigo or dizziness may occur. Reduction of dosage may alleviate symptoms. Therapy need not be discontinued, but such patients should be observed with extra care.

Warning: Patients should be cautioned not to drive vehicles or use hazardous machinery while on therapy.

Precautions: In cases of impaired or suspected renal impairment, use with greater caution and reduce dosage in proportion to extent of impairment. Transient elevations of BUN have been reported. As a routine precaution, appropriate blood studies should, therefore, be made during prolonged therapy.

As with all polypeptides, the possibility of muscular weakness, including apnea, due to inadvertent overdosage or normal dosage in the presence of impaired renal function, should not be overlooked. In cases of apnea, medication should be promptly discontinued and assisted respiration given until serum levels fall and normal breathing is restored.

Other antibiotics, such as kanamycin, streptomycin, dihydrostreptomycin, polymyxin, and neomycin, may also have varying neurotoxic or nephrotoxic potential. They should be used with great caution concomitantly with Coly-Mycin Injectable (colistimethate sodium).

For deep intramuscular injection only.

Dosage: By the I.M. route only, in 2 to 4 divided doses ranging from 1.5 to 5 mg./Kg./day (0.7 mg. to 2.3 mg./lb./day). Average adult dose is 2.5 mg./Kg./day (1.1 mg./lb./day). In the presence of bacteremia, septicemia, or other serious infection, greater than average doses may be required; however, maximum daily doses should not exceed 5 mg./Kg. (2.3 mg./lb.) where renal function is normal.

Not recommended against Proteus.

Colistin is also available (as colistin sulfate) in: Coly-Mycin® Pediatric for Oral Suspension (not for systemic use), and Coly-Mycin® Otic with Neomycin and Hydrocortisone.

Full information is available on request.

CI-GP-69-R2

WARNER-CHILCOTT Morris Plains, New Jersey

How long will it take her to recover from her hip fracture if she just doesn't care?

Does she really care?
s she alert, encouraged,
ositive and optimistic
bout getting completely
ell soon?
Or has she given in to
he demoralizing impact
f confinement, disability
nd dependency?
When functional fatigue
omplicates convalescence,
lertonic can help…

Pleasant-tasting Alertonic is pipradrol hydrochloride —an effective cerebral stimulant whose gentle analeptic action helps counteract the apathy and inertia that can often delay convalescence—together with an excellent vitamin and mineral formula, in a satisfying 15% alcohol vehicle.

Nothing fosters confidence and a sense of well-being better than your own personal warmth, understanding and encouragement together with Alertonic to help insure prompt response.

Adequate dosage is important: Prescribe Alertonic— one tablespoonful t.i.d., 30 minutes before meals…tastes best chilled.

And for your patient's sake, prescribe Alertonic in the convenient, economical one-pint bottle.

Alertonic®

Available Only On Prescription

Each 45 cc. (3 tablespoonfuls) contains: alcohol, 15%; pipradrol hydrochloride, 2 mg.; thiamine hydrochloride (vitamin B_1) (10 MDR*), 10 mg.; riboflavin (vitamin B_2) (4 MDR), 5 mg.; pyridoxine hydrochloride (vitamin B_6), 1 mg.; niacinamide (5 MDR), 50 mg.; choline,† 100 mg.; inositol,† 100 mg.; calcium glycerophosphate, 100 mg. (supplies 2% MDR for calcium and for phosphorus) and 1 mg. each of the following: cobalt (as chloride), manganese (as sulfate), magnesium (as acetate), zinc (as acetate), and molybdenum (as ammonium molybdate).

*Multiple of adult Minimum Daily Requirement supplied.
†The need for these substances in human nutrition has not been established.

Indications: 1. Functional fatigue such as that often associated with: a depressing life experience or stressful time of life; advancing years; convalescence; limited activity or confinement. 2. Poor appetite and vitamin-mineral deficiency as they occur in: patients having faulty eating habits; geriatric patients who are losing interest in food; patients convalescing from debilitating illness or surgery.

Dosage: Adults, 1 tablespoonful; children (over 15 years old), 1 to 2 teaspoonfuls; children (4 to 15 years old), 1 teaspoonful. To be taken three times daily 30 minutes before meals.

Contraindications: As with other drugs with CNS stimulating action, Alertonic is contraindicated in hyperactive, agitated or severely anxious patients and in chorea or obsessive compulsive states.

Side effects: Reports of overstimulation have been rare. Patients who are known to be unduly sensitive to the effects of stimulant drugs should be observed carefully in the initial stages of treatment.

Minnesota Medicine at a Glance

Surgery for Carotid Artery — Garamella et al. Page 1669

This article describes the authors' favorable experience in re-establishing blood flow in patients who have had totally occluded carotid arteries. The conclusions may be debatable, but the article is well done and should be of interest to all readers who must manage the patient with this condition.

Complications from Anticoagulants — Reece and Olson Page 1677

Most doctors who have prescribed anticoagulants for thrombophlebitis or coronary disease have observed from time to time the usual insignificant episodes of ecchymosis, which are associated findings during the course of anticoagulant therapy. For these minor episodes there is no serious concern, but the possibility of major hemorrhages which endanger the life and health of the individual must be kept in mind, lest these complications get out of hand. A review of the relatively large series of major complications, occurring over a short period of time at one hospital, suggests the nature of these complications which may be easily overlooked. Certainly anticoagulant medication should not be administered lightly and without adequate control.

Augmentation Mammaplasty — Erich Page 1685

Indications for augmentation mammaplasty by Dr. John B. Erich is an excellent outline of the reasons for performing this procedure and also emphasizes when it should not be done. As the article states, the surgeon can anticipate psychological improvement when dealing with emotionally stable women who are sensitive and embarrassed about underdeveloped breasts. On the other hand, women with complex emotional problems which they attribute to small breasts will not benefit from surgery. Although not mentioned in this article, another use for these implants is following subcutaneous mammectomy for multinodular fibrocystic disease, preferably as a delayed two-stage procedure to minimize the chance of complications.

Surgical Emergencies in Pregnancies — Swenson and Runquist Page 1701

A massive intraperitoneal hemorrhage occurring in late pregnancy is a possibility and may result from an abnormality totally unrelated to the pregnancy itself. In order that such possibilities can be kept in mind, a review of Swenson's and Runquist's case report is well worth while. This is an instance in which prompt action undoubtedly saved the life of the patient.

Computer Medicine — Collen Page 1705

Dr. Morris F. Collen predicts that the computer will have the greatest technological impact on medical science since the invention of the microscope. Computer medicine will permit mass production of more data on more people and more data on the individual person. He predicts that within ten years every large hospital will have some form of computer system. He describes a computer operation used by the Kaiser Foundation Health Plan in San Francisco and Oakland with a two to three-hour automated multiphasic screening program. It seems that computer medicine is here to stay.

Complications of Stapedectomy — Eades Page 1743

In performing surgical operations to correct hearing loss, the dreaded problem of further sensori-neural hearing loss is usually associated with excessive surgical trauma. In order to have a fuller evaluation of these possible complications, a review of the seminar by Eades should alert one to these complications and the suggested method of diminishing them.

What's New in Hematology — Hagedorn Page 1757

The trend in transfusions today is to administer only the specific fraction of blood that is needed. Whole blood transfusions are now in a category of shotgun hematinic therapy. There is considerable difficulty in distinguishing fibrinolytic states from consumptive coagulopathies. The differential is essential for proper therapy.

The Phonocardiogram in Heart Diseases — Mueller and Grismer Page 1769

Phonocardiography is a graphic method of heart sound representation and can be helpful in diagnosis of heart diseases. Crucial points of precise timing of various heart sounds and murmurs can be established by phonocardiography. This information complements the auscultatory interpretation. The article describes the normal and many of the common abnormal sounds of heart disease.

Understanding

One meets with many men who have been fine students, and have stood high in their classes, who have great knowledge of medicine but very little wisdom in application. They have mastered the science, and have failed in the understanding of the human being. — William Mayo

---

New Nervous-Mental Hospital

St. Croixdale Sanitarium, located at Prescott, Wisconsin, broke ground in August for their new patient facility. The new building will house all departments of the hospital.

St. Croixdale Sanitarium has been operating since 1928. Their medical staff consists of five psychiatrists and neuro-psychiatrists. St. Croixdale participates in the Medicare program, is listed with the American Hospital Association, and has been approved and recommended for accreditation by the Joint Commission on Accreditation of Hospitals.

To do unto others as you would have them do unto you is well; but to do unto them as they would themselves be done by is better. — Comtesse Diane

some allergens are red...
whatever their color, shape, or size...
Benadryl®
(diphenhydramine hydrochloride)
PARKE-DAVIS
for control of allergic symptoms

Whether the allergen is red and round, or unseen and unknown, BENADRYL provides relief of symptomatic distress through its antihistaminic and antispasmodic actions. *PRECAUTIONS:* Persons who have become drowsy on this or other antihistamine-containing drugs, or whose tolerance is not known, should not drive vehicles or engage in other activities requiring keen response while using this product. Hypnotics, sedatives, or tranquilizers if used with BENADRYL should be prescribed with caution because of possible additive effect. Diphenhydramine has an atropine-like action which should be considered when prescribing BENADRYL. *SIDE EFFECTS:* Side reactions, commonly associated with antihistaminic therapy and generally mild, may affect the nervous, gastrointestinal, and cardiovascular systems. Most frequent reactions are drowsiness, dizziness, dryness of the mouth, nausea, and nervousness. BENADRYL is available in Kapseals® of 50 mg. and Capsules of 25 mg. 00666

Brewer Diagnostic Kits

Complete Serological Screening Tests For Syphilis . . .

The RPR Card Tests make use of a specially prepared, carbon-containing RPR Card antigen. The particle size and other characteristics of the carbon is such that when a reactive specimen is encountered, flocculation occurs, and there is a coagglutination which is readily visible to the naked eye. Individual tests, including the collection of blood and separation of plasma can be performed in 7 to 8 minutes.

Confirming earlier findings with the RPR Card Test[1-10] Reed[11] in reporting on 63,800 specimens had an overall agreement of 98.5% in a recent comparative study with other routine screening procedures.

The RPR Card Tests, with their low cost, ease of performance, high sensitivity and specificity, are without peer in situations that demand rapid testing of patients, enabling the physician to initiate prompt treatment of early infectious syphilis.

Specify the RPR Card Test as the screening procedure on serum or plasma samples submitted to your State Approved Laboratory.

Transillumination of the sinuses – diffuse shadow on right side of face indicates unilateral maxillary sinusitis.

In the common cold, Neo-Synephrine is unsurpassed for reducing nasal turgescence. It stops the stuffy feeling at once. It opens sinus ostia to re-establish drainage and lessen the chance of sinusitis. With Neo-Synephrine, in the concentrations most commonly used, decongestion lasts long enough for extended breathing comfort, without endangering delicate respiratory tissue. Systemic side effects are virtually unknown. There is little rebound tendency.

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Readers and Reviewers

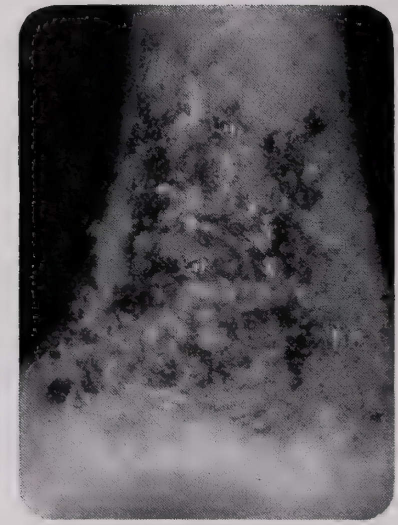
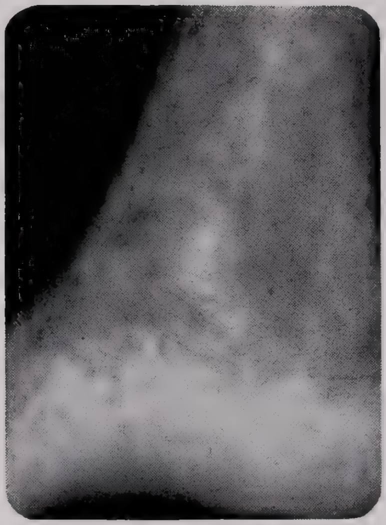
Eczema of many years... controlled in two weeks



Before treatment



After treatment—
with ARISTOCORT Topical
Ointment 0.1% for two weeks

ARISTOCORT® Triamcinolone Acetonide Topicals have proved exceptionally effective in the control of various forms of eczema: allergic, atopic, nummular, psoriatic, and mycotic.

In most cases responsive to topical ARISTOCORT, the 0.1% concentration is sufficiently potent. The 0.5% concentration provides enhanced topical activity for patients requiring additional potency for proper relief.

Administration and Dosage: Apply sparingly to the affected area 3 or 4 times daily. Some cases of psoriasis may be more effectively treated if the 0.1% Cream or Ointment is applied under an occlusive dressing.

Contraindications: Tuberculosis of the skin, herpes simplex, chicken pox and vaccinia.

Precautions and Side Effects: Do not use in the eyes or in the ear (if drum is perforated). A few individuals react unfavorably under certain conditions. If side effects are encountered, the drug should be discontinued and appropriate measures taken. Use on infected areas should be attended with caution and observation, bearing in mind the potential spreading of infection and the advisability of discontinuing therapy and/or initiating antibacterial measures. Generalized dermatological conditions may require systemic corticosteroid therapy. Steroid therapy, although responsible for remissions of dermatoses, especially of allergic origin cannot be expected to prevent recurrence. The use over extensive body areas, with or without occlusive nonpermeable dressings, may result in systemic absorption. Appropriate precautions should be taken. When occlusive nonpermeable dressings are used, miliaria, folliculitis and pyodermas will sometimes develop. Localized atrophy and striae have been reported with the use of steroids by the occlusive technique. When occlusive nonpermeable dressings are used, the physician should be aware of the hazards of suffocation and flammability. The safety of use on pregnant patients has not been firmly established. Thus, do not use in large amounts or for long periods of time on pregnant patients.

Available in 5 Gm. and 15 Gm. tubes and ½ lb. jars.

PHOTOGRAPHS COURTESY OF M. M. NIERMAN, M.D.

Aristocort® Topical Ointment 0.1% and Cream 0.1%, 0.5%
Triamcinolone Acetonide
Also available in foam form.

President's Letter

THIS ISSUE of Minnesota Medicine commemorates the State University of New York Upstate Medical Center, recognizing, as has been done in the past with other groups, the contributions to the practice of medicine by particular institutions.

The result of this editorial policy has been a broader contributor base, a wider reader interest and further contributions to current medical literature by an already outstanding medical journal.

The physician who has an article accepted for publication in any journal usually presents a new method, a new therapy or a new explanation for known facts documented by case reports of his personal experiences and by the evidence of other prior contributions in the area of his presentation.

The reader, on the other hand, weighs the article against his own experience, his knowledge, and his awareness of the status of the author before forming a conclusion.

Some readers, not in full agreement with the author, make a contribution of their own by letters to the Editor expressing a different conclusion or a different opinion.

If the objectivity and tempered reasoning that typify these dissenters could carry into other areas of physician disagreement, medical progress in socio-economics could better parallel progress in medical science.

Regrettably the very experience and knowledge which are of aid in evaluating a scientific presentation are lacking in physician appraisal in this other area, for no physician experience in the past can be applied to physician problems of the present. As a result, rumor is sometimes substituted for reason, prejudice for fact, and personal opinion for program.

Any division of the physicians of America, any group position adopted without full awareness of physician concensus, any decision arrived at without competent legal advice, certainly any suspicion or villification directed at those physicians sincerely following a course dictated by reason, moderation and full exploration is a disservice to medicine.

As our troubled medical present leads into a more troubled future, fragmentation of medical opinion and action may be our major problem and must be our major concern.

This being the concluding President's Letter of this official term, it would be incomplete without a sincere expression of gratitude for the opportunity to be of service, however inadequate to our Association, to know better many Association members, and to further observe the competence and efficiency of Mr. Brunn and his staff.

R P Buckley M.D.

R. P. Buckley, M.D.

The Crural Branches of the Phrenic Nerves*

Their Surgical Significance

MARTIN WYNYARD, M.D.
HAROLD D. KLETSCHKA, M.D.
Syracuse, New York

THE REGION of the esophageal hiatus has been of continued interest with regard to both its physiological and anatomical aspects. To understand the mechanisms controlling gastric reflux and to apply this knowledge to the treatment of hiatal herniation has constituted the principal challenge. Surgical intervention in the treatment of hiatus hernia at the present time yields inadequately predictable results, and this doubtless reflects an incomplete understanding of all the factors germane to constructing a repair that will reestablish the physiological state. Failure to study accurately the nerve supply to the crura of the diaphragm has contributed to this lack of understanding. The authors have drawn observations and conclusions based on anatomical studies that they and others have carried out. It is their hope that a presentation of this information will help to focus attention on the crural nerve supply and to stimulate thereby further clinical and experimental studies which might contribute benefit to surgical repair.

On reviewing standard anatomical texts it is apparent that information regarding crural innervation is very scanty and confusing. Most of these works of reference[1,2,3,4,5] dispose of the matter without express mention of the innervation of the crura or by simply indicating that the phrenic nerve is the sole motor nerve to its own half of the diaphragm. It is left open to question to which half of the diaphragm the esophageal hiatal musculature belongs. Illustrations do not show the innervation of the crura. In a description of the crural nerve supply found in one standard textbook[6] the following statement appears: ". . . the crura, derivatives of the prevertebral rectus, are supplied by the lower intercostal nerves, not by the phrenic."

It is obvious that an accurate understanding of the nerve supply to the crura could be very important in conceiving a proper surgical attack on hiatus herniae. A clear appreciation of this fact led Collis et al.[7] to carry out anatomical dissections to establish the pattern of innervation of the diaphragmatic crura. So far as we can determine, their report in 1954 detailed the first clear description of the crural nerve supply. They concluded that the muscle fibers arising from the right half of the central tendon (crural fibers) are innervated by the right phrenic nerve, while those arising from the left half are supplied by the left phrenic nerve. Because of this arrangement they further suggested that the fibers from the right crus which are on the left side of the esophagus are really part of the left side of the diaphragm. This arrangement is clearly understandable since the esophagus is an embryological midline structure.

---

*See editorial page 1851.

Observations

We have dissected the nerve supply to the diaphragmatic crura in three cadavers. Collis[7] has clearly shown the course the branches of the phrenic nerves take to reach the crura. We undertook to demonstrate the terminal distribution of each of these branches. Merendino[8] pointed out that the crural branch almost always presents as a separate, definitive nerve trunk. In our dissections we traced these nerves macroscopically as far as we could into the crural musculature (Figures 1 and 2).

The Left Crural Nerve

The left crural nerve, after reaching the abdominal aspect of the crus approximately 1.3 centimeters to the left of the apex of the esophageal hiatus, takes a caudad course to a point approximately 4 millimeters from the rim of the hiatus at the mid-hiatal level. The principal nerve trunk continues in the same direction but assumes a position at a greater distance from the margin of the hiatus (approximately 8 millimeters) at its lowermost aspect because of the convergence of the crural musculature away from the nerve in this area. The fibers can be traced

for a short distance (approximately 1.5 centimeters) beyond the lower level of the esophageal hiatus. At the level of the apex of the hiatus the left crural nerve leaves its superficial course on the undersurface of the diaphragm and continues within the muscle tissue approximately one millimeter below the surface. It receives a vascular accompaniment and distributes fine divisions seriatim predominantly in a medial and posterior direction.

The Right Crural Nerve

The right crural nerve reaches the right crus at the mid-hiatal level at approximately a right angle. It then enters the crus to a depth of about 1.5 millimeters on its abdominal surface and divides into a superior and an inferior division. A medial division (a tiny fiber that is traceable for only a few millimeters) quickly arises from the inferior division, and the latter then continues in a caudad direction. Initially, it is situated approximately 1.0 centimeters from the inner margin of the hiatus, but in its terminal portion this distance is reduced to about 3 millimeters. Largest of the right crural nerve divisions is the inferior division. The superior division also maintains its relationship to the hiatal inner margin.

The principal crural muscle tissue and nerve supply lie lateral and inferior to the esophagus. This anatomical arrangement is undoubtedly of physiological importance and of interest to the surgeon. Photographic demonstration of the anatomy of this region, while maintaining the in-situ structural relationships (Figures 1-a and 2-a), presented technical problems, and a wax cast was therefore prepared to overcome these difficulties and is photographically depicted in Figures 1-b and 2-b.

Discussion

The surgical significance of the crural nerves relates to their vulnerability as a consequence of their anatomical location and distribution, particularly in their terminal course. The left crural nerve during its initial course while gaining access to the crus is a superficial structure and can very easily be injured. For the most part, each

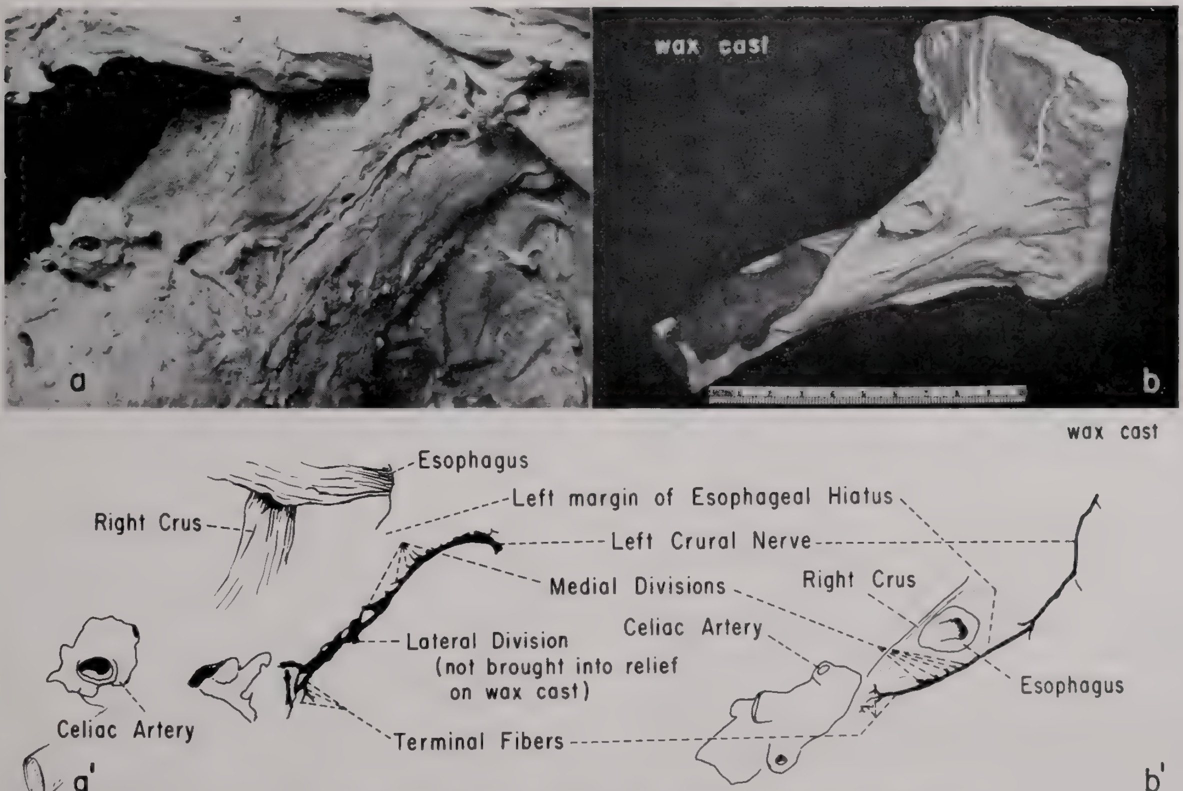

Fig. 2 — Left crural nerve showing its divisions and terminal fibers.

nerve occupies a position within the crura which is caudad to the mid-esophageal hiatus level and in close association with the hiatal margin. *Therefore, in dealing surgically with the esophageal hiatus, injury to the terminal branches of the crural nerves is most likely to occur in those instances in which the hiatus is closed posteriorly to the esophagus.* Furthermore, because of the superficial course the nerve fibers take on the abdominal aspect of the crura, an abdominal approach increases the hazard in such repairs. The close relationship that the terminal ramifications bear to the margin of the esophageal hiatus make it almost impossible to close the hiatus posterior to the esophagus from the abdominal aspect without incorporating these nerve fibers in the suture. At least it would suggest the loose application of the sutures or the employment of absorbable material.

In cases we have reoperated for hiatus hernia we have been impressed by the atrophy and scarring which takes place in the crura when the previous surgical efforts have been directed to this vulnerable region. Such cases often come to reoperation because of persistence or recurrence of reflux esophagitis following the initial repair. Infections and other disease processes (possibly secondary to hiatus hernia repair) in this region can result in destruction of these superficially situated nerve fibers with resultant muscle atrophy and a disturbance of the physiological state. The same consequences can result from an unskillfully performed abdominal vagectomy in which injury occurs to these nerve fibers.

In patients presenting with symptoms of reflux esophagitis it is important to determine whether previous injury to the phrenic nerve has occurred. Strauss[9] has shown that crushing of a phrenic nerve in man results in eventual complete atrophy of the ipsilateral hemidiaphragm. In surgical procedures within the lower thorax care must be exercised to preserve the posterior branch of the phrenic nerve if injury to the corresponding crus is to be avoided. Selective phrenic nerve paralysis with preservation of this branch has been utilized by Collis[10] in designing a surgical repair for hiatus hernia.

Summary

The terminations of the crural branches of the phrenic nerves are described and illustrated. Based on the pattern of innervation we propose that crural musculature to the left of the esophagus be referred to and considered as the left crus; and the crural musculature to the right of the esophagus, in similar manner, be identified as the right crus. The terminal branches of the crural nerves are distributed principally to that portion of each crus situated caudad to the mid-level of the esophageal hiatus and are in close association with the margin of that hiatus. The surgical significance of this pattern of distribution is discussed.

Acknowledgments

We are indebted to Dr. Philip B. Armstrong for making available to us facilities for carrying out the cadaver dissections. Dr. Warner S. Hammond has rendered invaluable advice and assistance regarding descriptive terminology and analyses bearing on the embryological and anatomical validity of our observations. We wish to thank Mr. Allen G. Ayres for the work he has contributed in making the wax cast and in providing illustrations. Our appreciation is extended to Mr. Charles G. Reiner and Mr. Paul A. Tackman for photographic work.

In a war of ideas it is people who get killed. — Lec

Shearing Injuries of the Subcutaneous Tissues

DAVID B. STARK, M.D.*
DAVID M. CONNELLY, M.D.*
Syracuse, New York

VISIBLE LACERATIONS and abrasions of the skin can be recognized by simple inspection. Injuries of bone can generally be recognized because of structural deformity, pain or interference with function. In contrast to this ease of diagnosis, the early signs and symptoms of the shearing injury which involves the tissues between the skin and underlying fascia or bone may be minimal, and the diagnosis becomes obvious only after the development of complications. In order to avoid these complications, awareness, early diagnosis and prompt appropriate treatment are essential.

Pathogenesis

A tangential force applied to the surface skin carries it over the underlying fascia or bone with resultant tearing of the intermediate tissues. The contusion or abrasive injury to the skin may be negligible. The force which shifts the skin tears the fat and, more importantly, the blood vessels. The thinner-walled veins are more likely to be involved. The smaller vessels may be injured and may ultimately thrombose. Fat necrosis may result.

The shearing force, having torn the tissues, creates a potential dead space, in which blood, serum or liquefied fat can collect. The stage is now set for the complications which not only make the diagnosis obvious but are responsible for significant morbidity.

Infection

The collection is an excellent culture medium. The byproducts of the growth of organisms may produce generalized symptoms such as fever, chills and malaise or may produce local involvement with pain, tenderness, increased swelling, induration and cellulitis. Progression to necrosis of

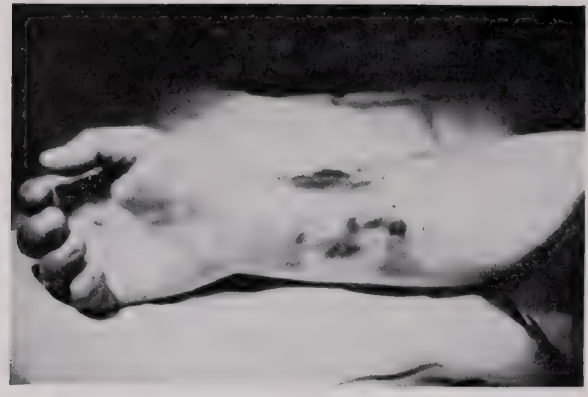

Fig. 1 — Wringer injury of forearm four days after accident. Note swelling, discoloration and skin necrosis.

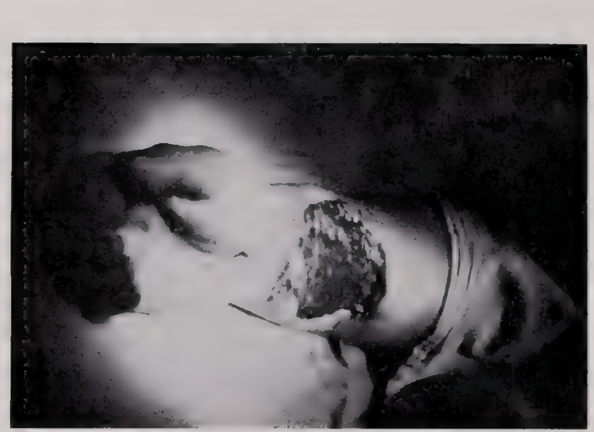

Fig. 2 — After one week a fine granulating wound is noted which is suitable for skin grafting.

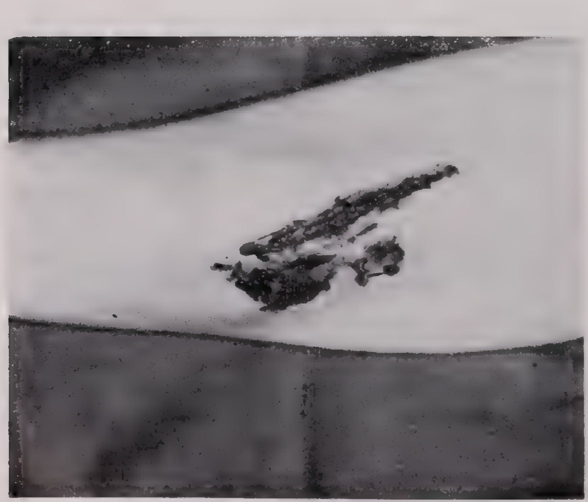

Fig. 3 — Irregular cutaneous necrosis of the pretibial area.

varying degree of the overlying skin may ensue.

Necrosis of the Overlying Skin Without Infection

The minimally traumatized skin, if allowed to return to contact with the viable bed from which it has been separated, will remain viable, and in the ordinary course of wound healing, the skin will be re-vascularized from the underlying base.

If, on the other hand, this minimally traumatized skin is elevated from the base by blood, serum, or liquefied fat collected in the dead space, revascularization from the base cannot occur. The deprivation of the skin over the collection is associated with progressive edema, progressive thrombosis of the previously minimally injured vessels, and necrosis of the skin with full thickness loss.

Treatment

Proper care of such an injury requires the recognition of the nature of the undermining and the potential for the formation of a collection of serosanguineous fluid or other tissue products in the dead space. This requires close observation and a high index of suspicion.

Once the collection has been recognized, it should be evacuated promptly before the insidious process of progressive damage to the overlying skin develops.

The early changes are often reversible if the elevated skin can be maintained in contact with the vascular bed after evacuation of the collection. Recurrence of the collection may be prevented by suction catheter drainage or pressure dressings depending upon the location and character of the injury.

* * *

The wringer injury is the classical example of this type of injury.

Case Reports

Case 1.

A sixty-two-year-old woman had caught her right hand and forearm in the wringer of her washing machine four days prior to examination. At the time of injury a capable general surgeon's examination showed minimal skin damage and no evidence of hematoma in hand or forearm. He applied a pressure dressing and re-examined the patient two days later. She had had no discomfort during the two-day interval.

Examination (Figure 1) showed edema of the tissues of the forearm and hand, with fluctuance on the dorsum of the hand. There was tense fluctuance on the flexor aspect of the distal forearm with blistering of the skin over a 10-cm. area on the flexor aspect. There was black necrosis of a segment of skin 2.5 × 6 cm. in size at the junction of the middle and lower thirds of the flexor aspect of the forearm. Movement of the hand, wrist and forearm was only slightly limited by the tenseness of the tissues.

At operation, the necrotic skin on the flexor aspect of the forearm was excised. Serosanguineous material gushed from the subcutaneous tissues. The fat in the subcutaneous region had been partially avulsed and was unattached beneath the skin. This was removed. Dorsal incisions were made in the second, third and fourth web spaces. Through these 2-cm. stab wounds, serosanguineous material was evacuated. Penrose drains were inserted to maintain drainage. The entire forearm and arm were wrapped in a bulky dressing. An anterior plaster slab splint was used to immobilize the area. Seven days later the skin on the dorsum of the hand and the flexor aspect of the forearm was nicely seated on the underlying tissues. A good granulating base was present (Figure 2). The defect at the site of removal of the necrotic skin was repaired with a split-thickness skin graft. Uncomplicated healing resulted.

* * *

An injury of the extremity not involving deeper structures and similar to the wringer injury of the upper extremity can frequently be recognized.

Case 2.

A seventy-three-year-old patient fell three weeks prior to admission with a resultant soft tissue abrasion on the left leg. Marked bruising and swelling were noted, but the skin appeared to be intact. There was a gradual darkening of the skin overlying the swollen area. Examination showed a doughy consistency on palpation with irregular areas of frank cutaneous necrosis (Figure 3).

At operation the eschar was broken away from the normal skin and a small amount of old dark blood ran freely from the wound. The eschar was excised sharply. The posterior aspect of the eschar was noted to have adherent currant-jelly clot. The base of the wound was filled with a clot measuring approximately one inch in thickness and extending well out into the soft tissue and beneath the skin which had been elevated from the base. All of the clot was removed and the wound was irrigated thoroughly (Figure 4).

A thin split graft was applied to the resultant open wound.

Redressing after one week showed a complete take with healing of the wound.

* * *

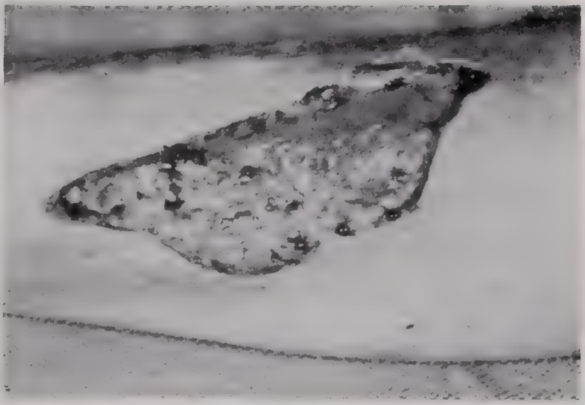

Fig. 4 — Removal of the clot and irrigation result in flattening of the cutaneous surface. This wound is ready for grafting.

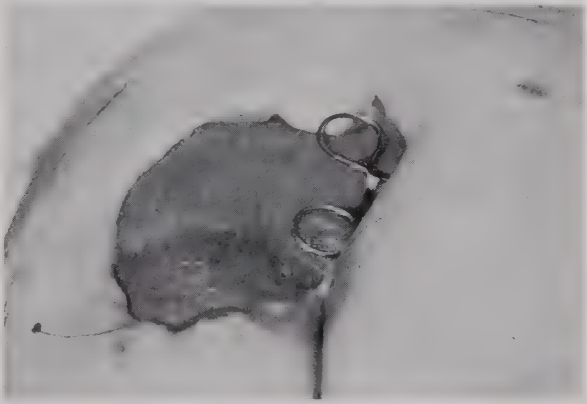

Fig. 5 — Granulating wound with Kelly clamp inserted beneath the undermined flap of the right buttock. Prompt evacuation of this hematoma prior to necrosis of the skin would have decreased this patient's morbidity.

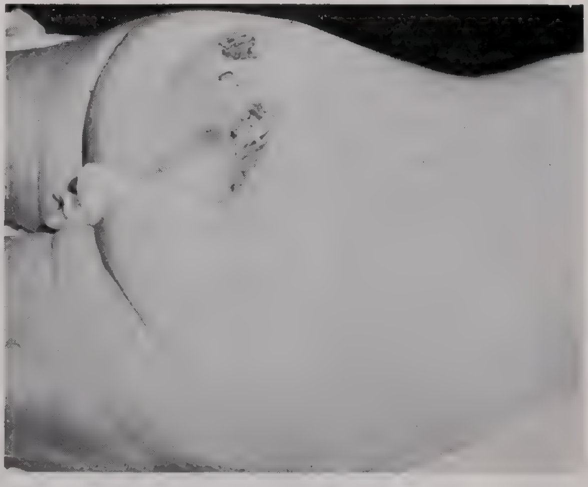

Fig. 6 — Shearing injury of the sacral area. Note the minimal involvement of the skin; yet there is a sizable hematoma.

On occasion, the injury may be completely unrecognized until late after the development of complications.

Case 3.

A fifty-year-old woman, involved in an auto accident, was admitted to the hospital for observation because of some contusions and general discomfort. No specific injuries were noted. Because her husband was more seriously injured and the patient had no place to go locally, she remained in the hospital with no significant complaints other than general discomfort.

On the sixth day following injury, the patient began to develop a low grade temperature elevation, which persisted and increased in severity without apparent cause. Two weeks following injury, redness and increased tenderness and swelling were noted in a contused area of the sacral region. Eighteen days following the injury, there was necrosis of the skin over the sacral area with associated inflammation and underlying fluctuance. On the twentieth day following injury, the area of necrotic skin was debrided. A copious amount of foul-smelling sanguinopurulent material with liquefied fat was evacuated. In the days following this procedure, a dressing program was instituted to promote healing. Consultation was requested three weeks later, at which time examination showed a skin defect 10 × 15 cm. in size overlying the sacral and coccygeal area. The bed of this defect was granulation tissue. The skin edges were undermined for a distance of from 6 to 15 cm., with the greatest area of undermining in the region of the right buttock where involvement extended laterally to the right trochanteric area (Figure 5).

Six weeks following the original injury and twenty-two days after the debridement and drainage, an operation was performed to remove the granulation tissue of the undermined area. Primary closure of the defect was performed. The sacral wound healed well. The patient was dismissed from the hospital three weeks after repair of the defect.

* * *

Case 4.

A moribund patient with general systemic problems developed a large fluctuant mass over the sacral coccygeal area with minimal superficial skin changes (Figure 6).

Comments

Not infrequently the decubitus of a paraplegic or a moribund patient may in fact be the result of shearing forces exerted on the tissues rather than due to simple ischemia from pressure, as the word pressure-sore implies. The shearing force may be more prolonged and repeated. This is particularly common in the sacral area. The patient is placed sitting in a chair or in bed with the head of the bed elevated. The body slides down or slumps due to the effects of gravity, the skin remaining fixed at its point of contact with the chair or bed. The underlying skeletal (sacral coccygeal) area moves away and a resultant tear occurs in the subcutaneous tissues. It seems likely that there is also some effect in the form of pressure ischemia as well as tension ischemia, producing death of the intermediate tissues. This is the type of mechanism which produces the bulging, inflamed fluctuant mass over the sacrum or sacral coccygeal area, not associated with necrosis of the overlying skin in the early stages.

Conclusion

Early recognition and prompt adequate treatment can prevent the complications and thereby reduce the morbidity of this type of injury.

Oliver Wendell Holmes to the Young Practitioner

I warn you against all ambitious aspirations outside of your profession. Medicine is the most difficult of sciences and the most laborious of arts. It will tax all your powers of body and mind if you are faithful to it. Do not dabble in the muddy sewer of politics, nor linger by the enchanted streams of literature, nor dig in far-off fields for the hidden waters of alien sciences. The great practitioners are generally those who concentrate all their powers on their business. If there are here and there brilliant exceptions, it is only in virtue of extraordinary gifts, and industry to which very few are equal.

Tomography* of the Respiratory Tract

Use of Polytome

E. ROBERT HEITZMAN, M.D.**
ALFRED S. BERNE, M.D.**
MICHAEL F. KIESS, R.T.**
Syracuse, New York

THE PHILIPS-MASSIOT Polytome is designed and engineered so that a wide range of tomographic techniques is available for clinical exploitation. Therefore a thorough knowledge of the technical considerations is necessary in order to tailor the tomographic examination most satisfactorily to the problem at hand. It is our purpose to emphasize the advantages and disadvantages of the various unique features of this equipment as they apply to the respiratory tract so that thoughtful technical planning of the examination will produce the best results.

The Polytomographic Technique

This unit offers several pluridirectional motions for tomography. The most complex movement, the hypocycloidal* motion, produces thin sections (1.3 mm.) of fine detail. The efficient blurring effect results in a tomogram virtually free of disturbing parasite shadows. However, the hypocycloidal motion requires an exposure time of six seconds (Figure 1).

In addition, the Polytome permits linear, elliptical, and circular tomographic movements with exposure times of three seconds for the elliptical and circular motions and .4 to 1.5-second exposures for linear motion. Because the machine allows one to select the direction of the long axis of the linear and elliptical motion, maximum blurring can be obtained by orienting the long axis perpendicular to the major axis of the dominant shadows to be erased, without changing the usual patient position on the table.

Disadvantages

Disadvantages become apparent in apply-

**From the Radiological Service of the Syracuse Memorial Hospital and the Radiology Department of the State University of New York, Upstate Medical Center, Syracuse, New York.

This investigation was supported in part by the John A. Hartford Foundation.

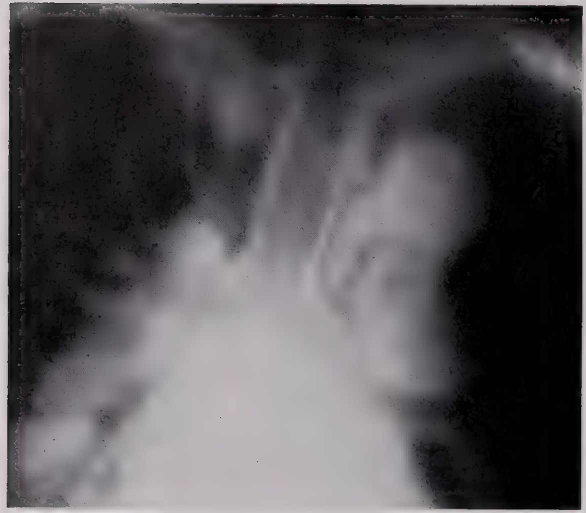

Fig. 1 — *Pneumomediastinogram.* This section was made 11.5 cm. from the table top with the patient supine. Hypocycloidal motion was used. Multiple discrete mediastinal lymph nodes are visible. The erasure of extraneous shadows lying out of the plane of interest is noteworthy.

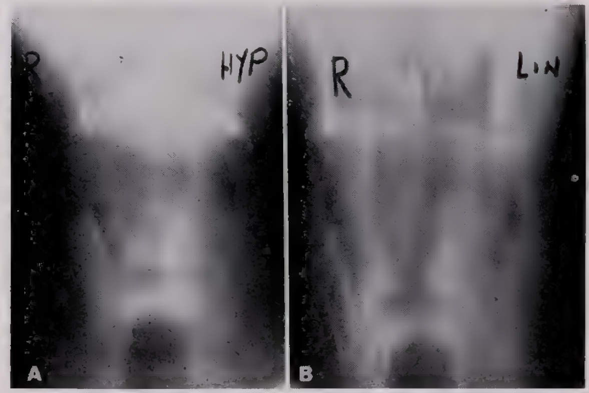

Fig. 2 — *Laryngeal tomograms.* Patient phonating and tomogram made 18 cm. anterior to the table top. (a) Hypocycloidal motion (6 secs.) 55 KVP, 100 MA. Despite low KV and close coning there is inferior contrast and lack of detail because of the long exposure. (b) Linear motion, 50° arc (1.3 secs.), 70 KV, 150 MA. Detail is superior and the blurring of extraneous shadows adequate.

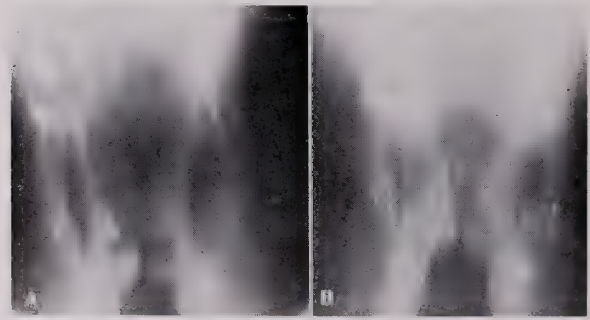

Fig. 3 — *Laryngeal tomograms.* AP sections made 14 cm. anterior to the table top. Linear motion was used. There is a small mass on the right vocal cord. (a) Inspiratory phonation. (b) Phonation.

ing the most highly refined motion to various problems in the respiratory tract. The hypocycloidal motion can be used only where absolute immobility of the part is possible. For example, the phonating larynx, the pulsating heart and blood vessels, and a very sick patient unable to cooperate frequently prevent the use of hypocycloidal motion.

The Efficient Blur

The efficient blur produced by hypocycloidal motion in the regions above and below the plane of interest results in an over-all grayness of the tomograms. This can be minimized by using low KV and high MAS and by decreasing scatter with cones. The lack of contrast may be especially troublesome in regions where the contrast is already low. This is true in tomography of the larynx because the soft tissues do not contrast well with the relatively narrow laryngeal air column (Figures 2 and 3).

Localization of Small Lesions

The thinness of the cut made by the hypocycloidal motion may make initial localization of small pulmonary shadows difficult. Frequently, thicker linear cuts are needed for localization purposes; then thin hypocycloidal sections are used for detailed analysis (Figures 4-a and 4-b).

"Satellite shadows" result when using complex motions and may be very troublesome. They represent the outer limits of the dispersed shadows of the structures which lie out of the plane of interest and are especially evident where there is considerable difference in density of the parts being examined, e.g., ribs and lung. They are especially conspicuous in the vicinity of the lateral chest wall and are produced by the axillary portions of the ribs when a lesion in this location is under study. This problem can be minimized if the point of interest is centered under the central ray even though a portion of the exposed field extends beyond the chest wall. If the "satellite shadows" hamper interpretation, one may resort to the linear motion, sacrificing some detail and accepting some interfering blur shadows (Figure 5).

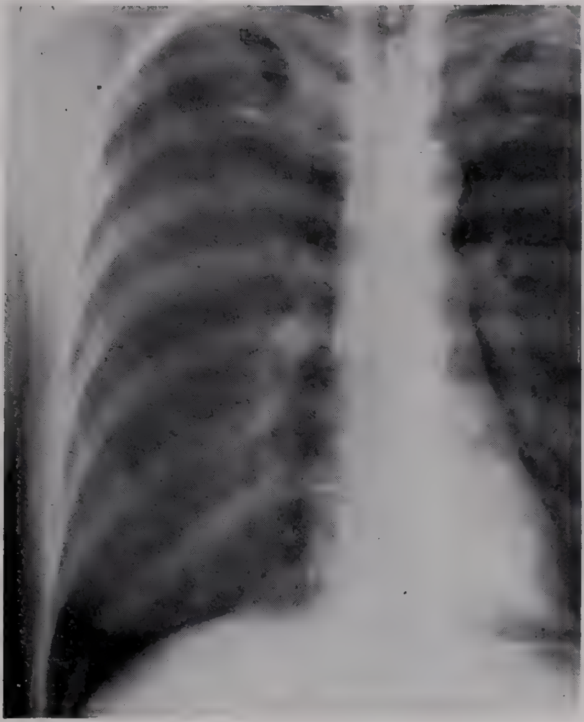

Fig. 4-a — *PA Chest.* A small nodule is visible in the right lower lung field just medial to the anterior end of the fourth rib.

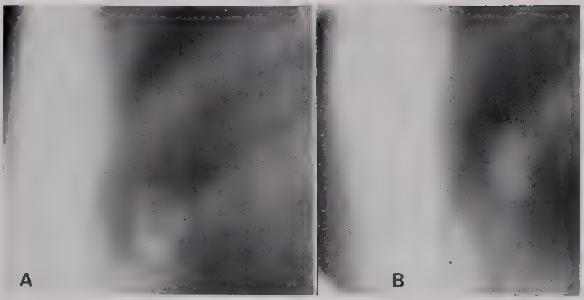

Fig. 5 — Subpleural peripheral pulmonary nodule proven to be carcinoma. (a) Linear cut. (b) Hypocycloidal cut. The detail is better on the hypocycloidal cut. The interference by the satellite shadows of the axillary portions of the ribs was minimized by centering over the lesion rather than the center cf the thorax.

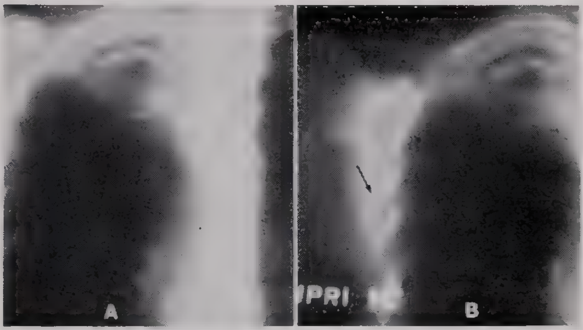

Fig. 6 — Intracavitary fungus ball. Section 8 cm. anterior to the table top. (a) Supine. (b) Erect. The fungus ball falls to the dependent inferior portion of the cavity when the patient is upright. Note the prominent "satellite shadows" (arrow).

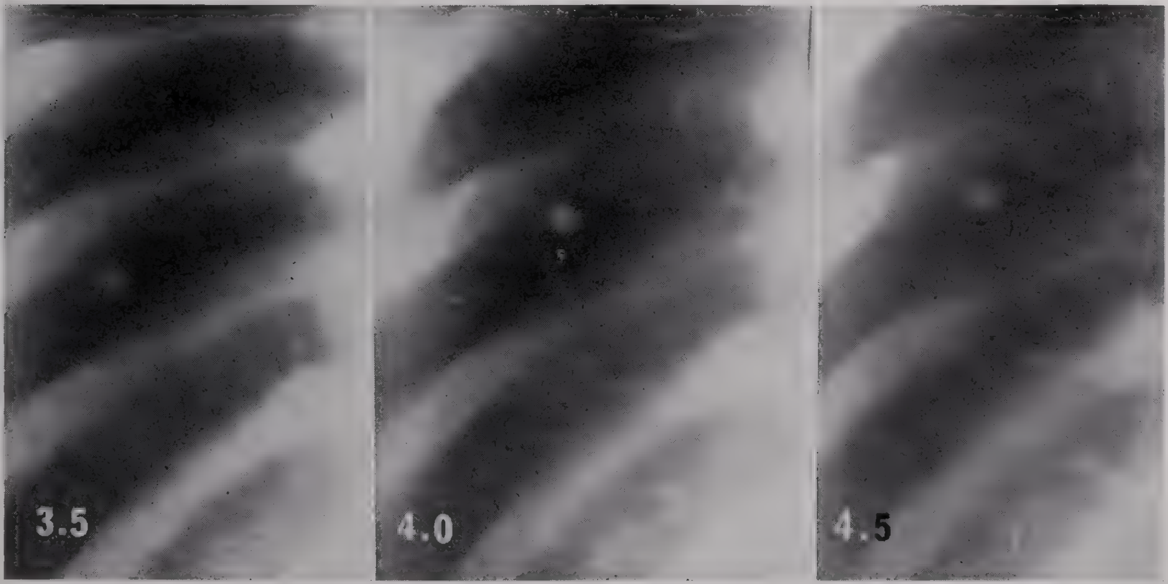

Fig. 4-b — Frontal AP tomograms made with hypocycloidal motion at 3.5, 4.0 and 4.5 cm. anterior to the table top. Maximal blurring of unwanted shadows was obtained and calcification was shown on the 4.0 cm. cut. Localization of the nodule for definitive study was difficult because of the thinness of the cuts.

The Mechanical Design

Stability

The Polytome is a very stable machine and thus is ideal for tomography. Stability of the unit is a great advantage over the tomographic attachments designed for use with regular radiographic equipment. Housing the Polytome in a room by itself is advisable. Tomographic examinations of the chest are frequently time-consuming and hence would often tie up a dual-purpose radiographic room. The "psychological block" to exploit fully the advantages of body section radiography disappears when adequate space is available exclusively for tomography. Of course, expense and overhead are greater in this circumstance.

The machine can be used with the patient in the erect or inclined position, whichever is advantageous in the delineation of cavitary disease and air-fluid levels (Figures 6 and 7).

Enlargement Technique

An additional cassette* holder is mounted below the normal cassette and grid holder which permits enlargement techniques. When coupled with a fine focus tube (.3 mm. focal spot) this apparatus produces detailed enlargements of 1.6 times. The routine tomograms enlarge 1.3 times. (The target-film distance and tomographic plane-film distance are always constant with this apparatus.)

The enlargement cassette holder can be tilted as much as 20 degrees from the horizontal. The geometry of tomography results in the plane of the section developing parallel to the plane of the film. Thus, inclined tomograms can be made. Several papers have appeared in the literature recently emphasizing the advantages of inclined tomography of the chest, especially to obtain visualization of the tracheobronchial tree and the pulmonary blood vessels. These results have been obtained by a fixed position of the tube with rotation of both patient and film. When using the Polytome, merely tilting the additional cassette holder produces inclined tomograms (Figure 8).

The first commercially available polytome would not permit routine radiographic examination because it lacked a conventional Potter-Bucky diaphragm. A new unit is available from Philips-Massiot which allows routine Bucky radiography in addition to Polytomography. However, this new unit cannot be used in the erect position.

Summary

The use of the Polytome in the respiratory tract has been reviewed. In the respiratory tract the full range of versatility of the

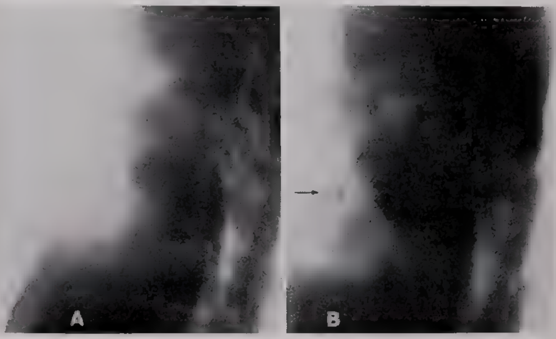

Fig. 7 — Pulmonary abscess cavity. Linear motion. (a) Supine 11.3 cm. anterior to the table top. A parenchymal density is seen without evident cavity. (b) Erect 11.0 cm. anterior to the table top. The air fluid level present indicates pulmonary cavitation (arrow). Tomography with the patient erect is invaluable to demonstrate cavitation.

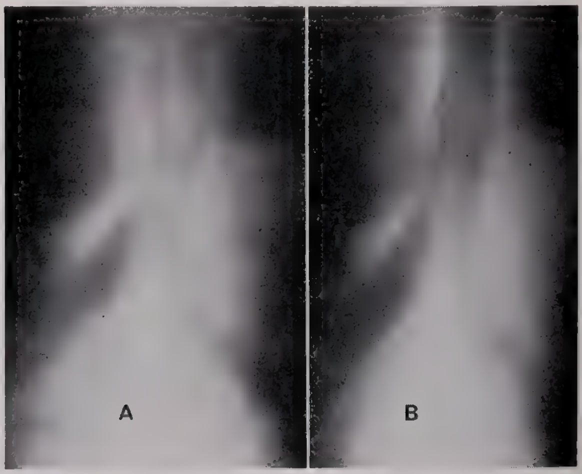

Fig. 8 — Tomography of the tracheobronchial tree. Hypocycloidal motion 11 cm. anterior to the table top. (a) Conventional AP tomogram. The film is parallel to the table top. The proximal trachea is not demonstrated. (b) Inclined AP tomogram. The cassette holder was tilted 15° to parallel the trachea. The entire plane of the trachea is in focus as is the plane of the carina and right and left main stem bronchi.

equipment can be exploited. Thorough knowledge of various technical considerations is mandatory to produce the best tomographic studies. When these factors are properly employed the resultant high quality tomograms add immeasurably to the roentgen evaluation of respiratory tract problems.

IT'S THE LAW

Medical Texts Admissible Only to Test Expert Knowledge, Not to Prove Medical Theories

Medical books and treatises are not admissible to prove the truth of statements contained therein, the Supreme Court of Washington said. Moreover, even though such writings are admissible to test an expert witness' knowledge, their authoritativeness must first be proved if the witness refuses to concede it.

An article was introduced in a suit by a department store customer for injuries sustained on an escalator in the store. A doctor who testified as an expert witness was cross-examined on an article which appeared in the Journal of the American Medical Association, entitled "Survey of One Hundred Cases of Whiplash Injury after Settlement of Litigation." The article indicated that a substantial number of persons having whiplash injuries recovered after the termination of litigation.

In commenting on the article, the court declared that, "it seems to us no more entitled to be called a medical treatise than any other statistical study."

Even assuming the article to be a medical treatise, it was not admissible because it was not established as authoritative, and the doctor had not conceded it to be such. He had testified that he read the article, but he did not concede that he regarded it as other than a statistical study.

The court agreed that an expert should not be permitted to block cross-examination by refusing to concede that a text or treatise is authoritative. However, if he does refuse to concede that point, then the burden of proving that the text or treatise is authoritative is upon the cross-examiner. In this case, the burden was not sustained, the court concluded, since there was no evidence that the views expressed in the article were other than those of an individual doctor, based on a survey made by a senior medical student. Therefore, the jury should have been instructed to disregard that portion of the cross-examination relating to the article, either because it was not a medical treatise or, if it was a medical treatise, because it was not established to be authoritative.

Dabroe v. Rhodes Company, 392 P.2d 317 (Wash., May 14, 1964)

Science commits suicide when it adopts a creed. — T. H. Huxley

Moliere on Doctors

Dr. T.: Sir, we have been discussing your daughter's illness, and my own view is that it arises from overheating of the blood. My advice is therefore — bleeding as early as possible.

Dr. D.: In my opinion the trouble is a putrefaction of humours caused by a surfeit of er - er - something or other. My view is that she should be given an emetic.

Dr. T.: In my opinion an emetic would kill her.

Dr. D.: On the contrary, I maintain that to bleed her now would be fatal.

Dr. T.: You would try to be clever. Don't forget how you cooked that fellow's goose the other day.

Dr. D.: What about the woman *you* sent to glory only three days ago?

Dr. T.: If you don't have your daughter bled without delay, you can take it she's done for.

Dr. D.: If you *do* have her bled, she won't last a quarter of an hour.

Dr. F.: Aren't you ashamed, gentlemen, to show so little prudence? Men of your age quarreling like a lot of hot-headed boys! Do you not realize how such quarrels damage our reputation? If we are not careful we shall do ourselves irreparable harm. I am not concerned for myself, because, thank Heaven, I am now comfortably off. Come rain, come shine, dead men tell no tales, and I no longer need to rely on the living. But these disputes do Medicine no good. Since Heaven has so willed that all down the ages people should continue to put unquestioning trust in us, let us not risk disabusing them with these outrageous rivalries. Let us continue to profit from their gullibility so far as we can. After all, we aren't the only people who seek to make use of human frailty. Everyone endeavors to turn other people's foibles to his own advantage. . . . But of all human foibles love of living is the most powerful. And that is where *we* come in, with our pompous technical jargon, knowing as we do how to take advantage of the veneration which the fear of death gives to our profession. Let us therefore seek to preserve the high esteem with which human folly endows us. Let us maintain agreement in the presence of our patients. Thus we may take to ourselves the credit when their maladies end happily, and put the blame on nature when they don't. Let us not, I say, wantonly weaken that persistent delusion which fortunately provides so many of us with our daily bread and enables us, from the money of those we put under sod, to build a noble heritage — for ourselves.*

The above dialogue is a classic example of Moliere's inimitable satire: mischievous in tone — with just a touch of malice but with no trace of bitterness. In the farce L'Amour Medecin (Love's the Best Doctor) several physicians are called into consultation to diagnose the malady of a young woman suffering from nothing more than love-sickness. Throughout the comedy the medical profession is mercilessly scored: for its arrogance, pretentiousness, intransigence and authoritarianism. Moliere's doctors resent patients who recover from diseases diagnosed as incurable and likewise patients who die in the face of favorable prognoses. Such unorthodox outcomes constitute an affront to the corporate dignity and infallibility of the medical profession.

L'Amour Medecin was written in 1665 and was an immediate and hilarious stage success.

Acute Arterial Occlusion in the Lower Extremity

ROBERT O. GREGG, M.D.
Syracuse, New York

SUDDEN ARTERIAL occlusion urgently demands careful differential diagnosis and an accurate appraisal of the patient's total cardiovascular status in order to institute the proper treatment at the proper time. The prime problem in differential diagnosis is that of acute venous thrombosis. Here one may err in thinking the patient has an acute arterial occlusion when in fact he has acute venous occlusion with much arterial spasm. More often muscle ischemia secondary to acute arterial occlusion is mistakenly taken for the early signs of acute thrombophlebitis in the calf, and sometimes embolectomy is delayed so long that irreparable damage is done to the muscle.

Evaluation of the Patient

The present cardiac status of the patient must be assessed: (1) to estimate whether or not a poor cardiac output contributes to the peripheral ischemia; (2) to assess the patient's degree of cardiac compensation with particular reference to his ability to withstand anesthesia and the necessary surgical procedure to relieve arterial obtruction; and (3) to assess the total cardiac capacity of the patient in the future, because total cardiac capacity will determine whether or not one should settle for an extremity with claudication or whether one should go "all out" to restore circulation to normal.

Once the differential diagnosis is established between venous and arterial occlusion and the cardiac status is evaluated, then one must decide what the fate of the affected extremity is likely to be without surgical intervention, where the obstruction is, and (if the extremity is not likely to survive without surgery) what type of surgery is necessary to restore the circulation of the extremity to normal. The differentiation between acute arterial thrombosis and acute embolism becomes important, because in most instances embolectomy can be carried out under local anesthesia with minimal trauma, whereas acute arterial thrombosis in most instances will require general or spinal anesthesia and some type of grafting procedure.

We have had occasion to review the records at the University Hospital as well as others from our own personal experience in the past 13 years, and after critically analyzing the management of these patients by ourselves and others we have arrived at a plan of evaluation and management which we would like to present.

Differential Diagnosis

Acute arterial occlusion must be differentiated from acute venous thrombosis. Two illustrations will suffice to indicate the importance of this differential.

Venous Thrombosis with Arterial Spasm

The author was called by a surgeon in another city to consult. The patient was a physician's wife who three weeks before had developed what was thought to be a left lobar pneumonia. The day of the conversation the patient had developed a cold, numb, white, slightly swollen left lower extremity in which the surgeon was unable to feel the femoral pulse. He was concerned that the patient might have both acute venous thrombosis and acute arterial thrombosis. Upon our advice the patient was given 100 mg. of heparin by the intravenous route and transferred to our hospital. When she arrived four hours later the extremity was fairly warm; there was a good femoral pulse, and the extremity was more than two inches larger than the other, confirming the diagnosis of acute venous thrombosis with much arterial spasm. Review of the previous films and the previous history would indicate that she undoubtedly had suffered a pulmonary embolus three weeks previously and now had developed an acute obstructive iliac vein thrombosis.

Acute Arterial Embolus

The tender calf of acute muscle ischemia following acute embolization is unfortunately sometimes interpreted as a positive Homan's sign of deep venous thrombosis.

An elderly physician came into the hospital with what was thought to be a stroke from which he was recovering. He had had previous cardiac decompensation and had chronic atrial fibrillation. While he was in the hospital recovering from the "stroke", he developed pain and tenderness in the left calf. A medical resident made a note of this and said he thought the patient was developing acute phlebitis. The following morning he was seen by his attending physician who recognized that he had no pulse distal to the femoral, that this extremity was colder than the other and that the muscle power in this calf was deficient. Fortunately for this patient an embolectomy some 24 hours after the onset of his pain was still successful in restoring circulation to this extremity.

Ischemia — Diminished Cardiac Output

Occasionally one finds an ischemic extremity in which a poor cardiac output contributes markedly to the ischemia. When the cardiac output is improved the ischemia disappears. The cardiac output may be markedly diminished because of severe tachycardia or marked bradycardia.

While at a cattle auction a 78-year-old cattle buyer collapsed because of pain, numbness, and inability to use the left leg. When he was brought to the hospital he had very little motion in the calf of this extremity and absent vibratory sense in the foot. He had no femoral pulse on this side, but as one approached the aorta one noted that his pulse rate was actually 26. He gave no history of chest pain and the EKG showed only acute complete heartblock with idiopathic ventricular rhythm. On questioning the patient we learned that he had suffered from one block claudication for the previous year. Although our tentative diagnosis was embolic occlusion of the left common iliac artery there was some question about how much of the ischemia of this extremity was due to the severe bradycardia. At any rate, it seemed reasonable to raise his rate to near normal before contemplating even a local approach to the left common femoral vessels. While in the x-ray department having a temporary pacemaker implanted by the venous route, the ischemia of the extremity promptly disappeared as soon as the heart was paced at 70 beats per minute. The patient has now worn a permanent pacemaker for two years and has done very well without the necessity for any surgery on his extremities.

Extreme tachycardia may also contribute to the severe ischemia of the extremity. A 56-year-old woman underwent resection of an abdominal aortic aneurysm. At the conclusion of the procedure it was noted that she had no pulse in the left foot; but the motion of the extremity was quite satisfactory and she had a popliteal pulse. Undoubtedly she had some embolic material in the distal popliteal vessel, but we were sure that the extremity would survive. The following day the pulse rate suddenly rose to 180 due to a supraventricular tachycardia to which she has been subject in the past. With the onset of this severe tachycardia she developed severe pain in the left hip and the left calf, with inability to use either the anterior or posterior musculature of the calf. Following carotid pressure and restoration of the pulse rate to 100 all signs of ischemia of the extremity promptly disappeared.

Embolism vs. Arterial Thrombosis

The differentiation between acute embolism and acute arterial thrombosis is important because of the differing surgical approaches required. In almost all instances of acute arterial embolism, particularly with the advent of the use of the Fogarty[1] catheter, almost all emboli can be removed through a small incision under local anesthesia. An exception to this, of course, would be embolism to the superior mesenteric artery in the abdomen. The presence of acute arterial thrombosis which threatens the life of an extremity or the suspicion of acute arterial thrombosis demands more extensive procedures on the blood vessels than can practically be carried out under local anesthesia. How can one be sure that the acute arterial occlusion with which one is faced is an embolus or a thrombus? First, almost all peripheral arterial emboli come from the heart or from a palpable peripheral aneurysm. In our experience involving some 68 embolic episodes, in only three instances was there no good documented source for embolization: either from atrial fibrillation in rheumatic or arteriosclerotic heart disease; from mural thrombus due to a recent myocardial infarct; from some preceding cardiovascular procedure; or more rarely from a femoral or popliteal aneurysm. Not infrequently the patient who presents an acute peripheral arterial occlusion gives no clear-cut history of myocardial infarction; but this should be looked for in the absence of atrial fibrillation. An EKG and subsequent enzyme studies usually lead to such a diagnosis. The patient who has marked peripheral sclerosis in other parts of his vascular tree (e.g., upper extremity or carotids), is more apt to have arterial thrombosis than embolism, particularly in the absence of a good primary source, and in our experience the patient with other severe atherosclerosis may require a grafting bypass procedure even in the presence of acute embolization. So from the practical standpoint the patient who has atrial fibrillation or who has had a recent myocardial infarct with no other evidence of peripheral sclerosis except in the affected extremity has a better than a 90% chance of having a peripheral embolism which can be treated simply under local anesthesia. The patient who has other signs of peripheral sclerosis will usually require extensive vascular surgery which cannot be done under local anesthesia.

Prognosis of the Extremity

The fate of an extremity not treated by surgical means is all-important in making the surgical decision. In the past 13 years we have, on first examination, carefully evaluated every extremity in which acute arterial occlusion has occurred, in order to project the fate of this extremity if unoperated. In the early part of this period some patients whose extremities seemed potentially not viable by our criteria were subjected to sympathetic blocks and some to heparin administration. In no instance, following either of these two modalities of therapy have we seen a reversal of impending gangrene which could be attributed to these methods of treatment.

With no therapy, we have seen spontaneous and dramatic improvement of an extremity which has had all the criteria portending gangrene. In these instances we postulate that an embolus which had lodged in the bifurcation had broken up into smaller particles and gone down into the muscular branches, leaving the main channel open.

Sympathetic Block and Heparin

It is true that in many instances an extremity which we would regard as survivable improves following a sympathetic block and also following heparin administration. In such instances where surgery is not absolutely necessary, either of these modalities of therapy would seem to be indicated to prevent thrombosis of smaller vessels. We have had no experience with low molecular Dextran in these instances.

Impending Gangrene

Following a critical analysis of all the case records, we have come to the conclusion that the status of the muscle in the extremity is the single most important prognostic factor. If the muscle is paralyzed and hard, rigor mortis has set in and no revascularization is possible. If the muscle is tender and still soft, with motor power diminished or absent, and if proprioception* is impaired, then this muscle in our opinion is suffering from severe ischemia but is still salvageable if the obstruction to the supplying artery is relieved. If motor power is completely gone, the blood supply has been effectively cut off. If motor power is merely impaired, there is less ischemia of the muscle. Tenderness is usually confirmatory evidence of ischemia. Proprioception or position sense is also related to the blood supply of the muscle. We have noted that often the skin seems to be intact when the muscle has already become infarcted. These criteria, we are sure, apply very specifically to all patients with acute embolism.

Surgery Indications and Contraindications

Given a patient with acute peripheral embolism the decision for or against surgical intervention depends upon (1) the projected fate of the extremity, and (2) the recoverability of the heart. If the patient has thrown an embolus from the atrium in the case of mitral stenosis which is correctable, then certainly the embolus should be removed even if the extremity would survive without surgical intervention. On the other hand, a patient who has suffered a severe massive myocardial infarct which had thrown off a peripheral embolus that was not threatening the extremity would hardly be a surgical candidate in order to cut down the possibility of future claudication. The occurrence of a peripheral embolus which is producing sufficient ischemia to threaten the life of the extremity is, in our opinion, a clear-cut indication for removal of the embolus even in the presence of moderate degrees of cardiac decompensation, for surely necessary amputation in such a patient carries a high mortality.

---

*See Test Your Word Score Page 1855.

The distribution of emboli according to location is about the same in our series as in those others reported in the literature and needs no comment.

It should be noted that the great proportion of patients have arteriosclerotic heart disease, but there is also a very high proportion of fresh myocardial infarcts.

Treatment

Early Operation

Embolectomy is very successful in restoring the circulation to normal if done early; but unfortunately it does not always correct the primary cause of the embolization. In the past three years, we have had occasion to operate on 21 patients for acute embolism. In 19 of these simple embolectomy was carried out and in two some grafting bypass procedure was judged necessary. In this period six patients had emboli above the inguinal ligament either aortic or iliac. Three were operated on under local anesthesia and all underwent exploration from below without opening the abdomen. Unfortunately, in this group there were three deaths, two of them of cardiac failure following coronary thrombosis, and one probably from an overlooked mesenteric occlusion. In the three survivors all extremities were normal. There were 15 patients who had emboli lodging below the inguinal ligament; in 11 of these a Fogarty catheter was used and in two a grafting procedure was necessary. Ten patients were operated on within 12 hours of the onset with no resulting peripheral ischemia. However, two of these died of other emboli to the brain.

Late Operation

Five patients were operated on after more than 12 hours; in this group only one patient did not require an amputation. One of these patients died of a cerebral embolus. In our total group of emboli seen in the past 13 years there have been 28 patients operated on who in the judgment of the operating surgeon had such severe muscle ischemia that gangrene would have ensued had they not had surgical intervention. In this group gangrene of the extremity occurred in only one patient, undoubtedly because an embolus in the popliteal artery was overlooked.

Local Anesthesia

The importance of local anesthesia for embolectomy wherever possible should be emphasized, not only because of its relative safety but because as soon as the arteriotomy is closed and the blood allowed to go down into the extremity the success of the procedure is immediately demonstrable by the motion of the muscle previously motionless. Localization of the embolus can usually be made by palpation in order to make the incision in the proper place. If the embolus lodges above the inguinal ligament and there are no femoral pulses and no signs suggestive of bowel ischemia, one can make bilateral femoral arteriotomies under local anesthesia. If the embolus lies below the inguinal ligament one can usually palpate the superficial femoral artery down to the point of occlusion. If this is not conclusive, then the point of occlusion can be quite simply picked up within a few centimeters by the use of an oscillometer.

Acute Arterial Thrombosis

Unfortunately our experience with acute arterial thrombosis has not been as happy as with peripheral emboli. An extremity may seem to be potentially viable today; tomorrow it may be much worse. Three case histories will indicate the problems of management.

Case 1.

A 77-year-old round-back male was admitted to the University Hospital with a sudden onset of coldness and with numbness of his left foot which had been present for four hours. On examination, sensation of the skin was absent up to the ankle; the second and third toes were dusky blue; there was still plantar flexion and dorsiflexion of the foot but absent proprioception in the great toe. In the course of the workup in the next two hours the chest film showed unequivocal evidence of carcinoma of the left lung. The presence of this obviously inoperable carcinoma in this particular patient made us pause overnight to decide whether or not to do anything for this extremity. The next day the second toe was definitely gangrenous, and it seemed obvious that the patient would soon lose his extremity if something were not done to correct the advancing gangrene. We therefore explored the left popliteal artery under general anesthesia and found it to be patent and soft, injected it with dye and discovered the runoff to be adequate. . . . We then put in a stretch dacron prosthesis from the common femoral to the distal popliteal, which functioned so satisfactorily that he was able to walk upon this leg for about eight months until forced to go to bed for the terminal stages of his bronchogenic carcinoma.

Case 2.

A 68-year-old female two years previously had suffered a right hemiplegia which left her with a residual spastic gait in her affected lower extremity but with return of speech and use of her upper extremities. About 18 hours prior to admission to the hospital she had developed pain and numbness of the right lower extremity with progressively increasing inability to move the musculature in her calf, anesthesia to the lower calf, and loss of proprioception. It appeared that gangrene would soon ensue, although the extremity at this time seemed to be potentially still viable. In view of the spastic situation in this extremity, however, it seemed unlikely that she would be able to handle a prosthesis. She was taken to the operating room and fortunately a graftable situation was found. A dacron prosthesis was placed between the common femoral and the distal popliteal, and since this graft was inserted she has been walking as well as before.

Case 3.

This elderly lady of 78 was in the hospital for a vein stripping of the left leg. The fifth day afterward she developed pain and numbness in the right lower extremity below the knee, with tenderness in the anterior tibial compartment. One could palpate the common femoral artery and superficial femoral artery down to the distal third of the thigh. The wrong clinical impression was then entertained by the author; he thought that the extremity was irretrievable and probably not reconstructable. An arteriogram done the following day showed to our surprise that the distal popliteal artery and all three of its branches were open. We then carried a saphenous vein graft from the common femoral to the distal popliteal, which has functioned now for more than a year with palpable dorsalis pedis pulse. However, delay had resulted in ischemia of the entire anterior tibial compartment of the muscle, which of necessity had to be removed. The defect was covered with a skin graft which necessitated hospitalization for about two months. The patient, however, is walking on this extremity, and although deformed it is probably better than an artificial limb.

Arteriography

We have used arteriography very infrequently in patients with acute arterial occlusions. The diagnosis and localization of peripheral emboli can usually be quite satisfactorily made on clinical grounds. Occasionally in a borderline case an arteriogram will show definitely by its configuration that the occluding matter is embolic rather than thrombotic. However, I think a word of caution is necessary in interpretation of arteriography with acute arterial thrombosis. It has been our experience that an arteriogram may show no peripheral runoff in the presence of acute arterial occlusion because there is simply not enough blood carrying the dye into the distal segment past the occluding thrombus. In general our approach to acute arterial thrombosis is that, if we are confident that the extremity will not survive without surgical intervention, we explore the distal popliteal artery directly. If the main trunk of the artery is open we usually inject iodine-containing dye to determine the patency of the distal tree. If this is patent then we go ahead with the grafting procedure. If the popliteal is occluded, then hopefully we gain permission for amputation.

Conclusion

We have pointed out the importance and the means of differential diagnosis between acute arterial thrombosis and acute peripheral embolism, indicating that emboli can be removed under local anesthesia by the standard simplified technique but that arterial thrombosis requires much more extended procedures requiring spinal or general anesthesia. A strong plea has been made for the accurate appraisal of the potential fate of the extremity at the time of the initial examination. Medical measures are advocated only in those extremities or for those patients whose extremities will almost surely survive without surgical intervention. It was pointed out that early embolectomy with occasional use of graft is almost always successful in preventing gangrene of the extremity. Acute arterial thrombosis has been shown to be a very insidious and difficult problem to handle; but an aggressive approach has resulted in the saving of some extremities which otherwise would have been lost.

Treatment of Rheumatoid Arthritis

Chemical and Surgical Synovectomy

DANIEL ELSTEIN, M.D.
Syracuse, New York

RHEUMATOID ARTHRITIS may be defined as a chronic inflammatory disease characterized by proliferative and destructive changes in joints leading to ankylosis and deformity. Galen[1] first used the word rheumatism in the first century A.D. However, no clear-cut classification of arthritis was made until Gerrod[1] in 1859 differentiated between osteoarthritis and rheumatoid arthritis. Nicholas and Richardson[1] first stated that in rheumatoid arthritis there are proliferative changes in joints, chiefly in the synovial lining, while in osteoarthritis the changes arise as a degeneration of cartilage.

Manifestations of Rheumatoid Arthritis

In the earliest stages of rheumatoid arthritis the disease is a synovitis, characterized by synovial hyperemia, edema, and increase in joint fluid. The synovialis may increase from a single-layer thickness to a great many cell layers. Synovial villi enlarge and hypertrophy.

The most significant and serious manifestation of rheumatoid arthritis is the pannus* formation over the articular surfaces. Pannus originates in the part of the synovial membrane bordering the articular cartilage and first appears as tongues of granulation tissue creeping from the periphery toward the center of the joint, producing destruction of cartilage.

Types of Treatment

The cause of rheumatoid arthritis is as yet unclear. While research for a specific etiology is in progress, attempts at treatment by non-specific therapy have been numerous. The materials used by the medical profession for this purpose through the years have been legion; among the most popular have been typhoid bacillus, a shotgun mixture of streptococcus and staphylococcus, colloidal sulphur, casein, colloidal gold, aspirin, butazolidin, steroids, and the antimalarials. Because rheumatoid arthritis is a disease of hyperplastic synovium, a more direct attack would seem to be based directly upon removal of the tissue.

---

*See Test Your Word Score Page 1855.

Chemical Synovectomy

A method of treatment which would remove the hypertrophic synovium completely and not subject the patient to an extensive surgical procedure and long convalescent period would be ideal. A chemical synovectomy with a nontoxic, cartilage-sparing, easily-injectable substance would certainly have many advantages over surgery. Such a chemical synovectomy has been attempted by the intra-articular use of nitrogen mustard and thiotepa. These substances are alkylating agents well known in the treatment of metastatic tumors. In contrast to thiotepa, nitrogen mustard is a local vesicant, contact with which can lead to a serious local reaction. Because of this feature of the drug we have concentrated our attention on the use of thiotepa.

Thiotepa is thought to act on the desoxyribose nucleic acid molecule of the rapidly developing cells of the hypertrophic synovium to prevent cell multiplication.

Alkylating agents have been used in the treatment of rheumatoid arthritis since 1951 when Diaz[2] reported using nitrogen mustard systemically in nine severe cases of arthritis with rapid relief of pain. Scherbel[3] and Scherbel, Schuchter, and Weyman[4] in 1957 published extensive experiences with nitrogen mustard in animal and clinical trials in which the drug had been administered via both the intra-articular and parenteral routes. In one group of 263 patients Scherbel[3] reported 88 percent rapid relief of symptoms but with recurrence of symptoms in all cases. Vainio and Julkunen[5] of Finland injected symmetrical joints with 25 milligrams of hydrocortisone and 0.5 milligrams of nitrogen mustard. Although the symptoms reappeared in each case, the mean extent of time of remission was 2.3 months. We have a small series of five patients in whom we have injected thiotepa into the involved joints. In all instances but one there was a rapid and dramatic relief of joint pain within 48 hours, followed by marked regression in synovial thickening. In each case there was a recurrence of synovial thickening and fluid within six months. In one patient patellectomy was performed six weeks after 60 milligrams of thiotepa was instilled

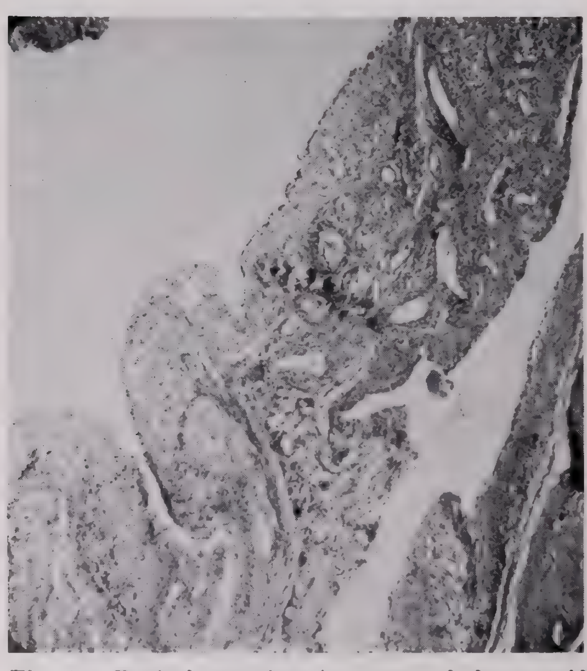

Fig. 1 — Typical synovium in a case of rheumatoid arthritis.

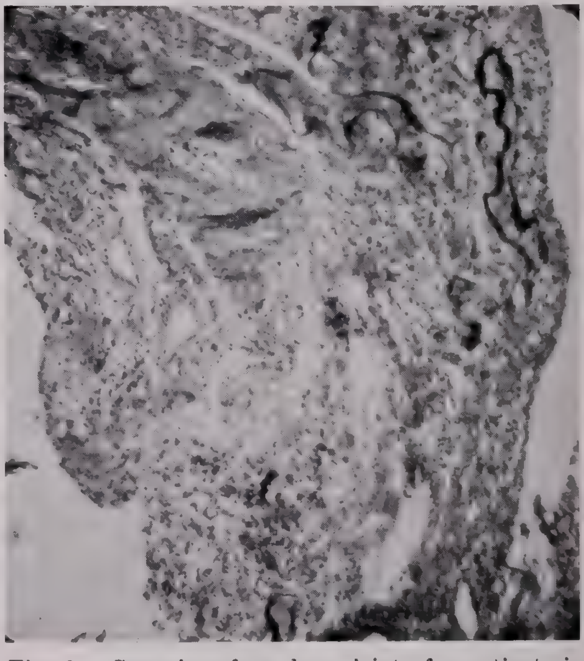

Fig. 2 — Synovium from knee joint of a patient six weeks after the injection of thiotepa into the joint. Note the marked fibrinoid necrosis.

into the knee joint. The synovium at the time of arthrotomy was reddish grey in color and not thickened. Microscopic examination revealed marked fibrinoid necrosis of the joint lining (Figure 2).

Surgical Synovectomy

Although the alkylating agents produce rapid remissions in rheumatoid arthritis, it appears that recurrences in the same joint are inevitable. Because of this observation we have abandoned chemical synovectomy in favor of surgical synovectomy. We believe that synovectomy is a worthwhile surgical procedure for the rheumatoid knee joint and for the metacarpophalangeal joints of the hand. The ideal joint for surgery is one with persistent chronic arthritis which has not improved with conservative treatment. The surgery should be undertaken before there is extensive joint and ligamentous destruction. Although the best results might be expected in patients whose articular cartilage has not yet been invaded, satisfactory results have been achieved in patients with moderately advanced joint destruction.

Results of Surgical Synovectomy

Aidem and Baker[6] reported on using synovectomy in 26 rheumatoid knee joints with 11 excellent, 12 good, one fair, and two poor results. Even in the group with fair and poor results there was no recurrence of the preoperatively swollen, boggy knee. We have performed synovectomy in 13 rheumatoid knees with eight excellent, two good, one fair, and two poor results.

Timing of Operation

The timing for surgical intervention is critical. We do not feel that synovectomy is indicated in the face of acute generalized arthritis. In such cases we employ systemic medical treatment and physiotherapy awaiting the cessation of the generalized activity to then treat the chronically involved joints. Preoperative physiotherapy stressing efforts to achieve full extension is extremely important. Preoperative splinting is indicated in patients who cannot otherwise attain full extension of the knee. Active exercises are encouraged. Often intra-articular steroids will reduce joint pain enough to improve knee motion.

Resumption of Motion

Early resumption of joint motion postoperatively is important. We encourage joint motion 72 hours following surgery. If the patient does not have a 90-degree range of motion in the knee within 10 days, we gently manipulate the joint under general anesthesia.

Conclusions

Rheumatoid arthritis is at present a discouraging disease to treat. It is unpredictable and often produces severe bone and joint destruction and total invalidism. Or it may spontaneously subside. We feel that in the patient who has chronic arthritis, rather than allow the condition to progress to produce severe joint deformity, an aggressive surgical attack on the wayward synovium is beneficial. Chemical synovectomy produces only a temporary remission. Further conclusions regarding chemical and surgical synovectomy in the treatment of rheumatoid joints await long-term studies involving large numbers of patients.

Madness

Madness is to think of too many things in succession too fast, or of one thing too exclusively. — Voltaire

Disease and Music

Tarantism

Endemic to the province of Apulia on the east coast of the Italian heel during the medieval era and epidemic throughout the scorching summer season was an exotic and baffling disease: tarantism. Its victims were called tarantists; its cause was the tarantula; and its only cure was the tarantella.

According to descriptions by reliable observers, Ferdinandus, a physician, Baglivi, an iatromechanist, and Kircher, a Jesuit father, the victims of the disease, immediately after being bitten by the 'deadly' spider, rushed out to the public street or market place and commenced dancing in a frenzy — with unmistakable and provocative overtones of alcoholic and aphrodisiac abandon.

The only remedy for the dance delirium was music, the wild and passionate tarantella, usually furnished by roving bands of musicians who proceeded from town to town capitalizing on the bizarre hysteria the summer's heat produced. To the tarantella the tarantists danced orgiastically until, too exhausted to continue, they stopped — supposedly cured. However, because of its insidious nature the disease abated only temporarily — to be reactivated by the heat of succeeding summers. Its incidence was highest among young people, though records show that a boy of five and a man of ninety-four once succumbed.

Naturally, doctors were dubious. One sceptical physician allowed himself to be bitten twice by the spider. His arm swelled up but no irresistible compulsion to dance seized him. Therefore it could not be the tarantula that caused the terpsichorean obsession. Then what? A mysterious neurosis, the doctors theorized. But then — whence came it? No one could explain!

However, like the Roman Empire itself, tarantism rose and fell — its etiology remaining obscure to the last. Only much later did historical perspective provide a clue to the enigma. The early natives of Apulia had been special devotees of the pagan cult of Dionysus with its orgiastic alcoholic and sexual rites. But the Church had peremptorily stopped all such demonstrations. Nevertheless, while Dionysian practices might be summarily prohibited, the urge to indulge in those practices could not be arbitrarily repressed. So the people continued to dance in the searing heat of the Apulian summers. Compelled to repudiate the traditional excuse for their annual extravagant orgies they simply substituted a socially more acceptable reason: the tarantula's bite — an act of God which did not fall within the Church's province.

The Difference

We must bear in mind the difference between thoroughness and efficiency. Thoroughness gathers all the facts, but efficiency distinguishes the two-cent pieces of non-essential data from the twenty-dollar gold pieces of fundamental fact. — William Mayo

Editorials

An Architect of Medical Education

ANY REVIEW of the impact of the University of Minnesota on the Upstate Medical Center of the State University of New York would be incomplete without some recognition of the unique contributions of an alumnus of the University who did not graduate from its medical school — Dr. Carlyle F. Jacobsen (Ph.D. in psychology, 1928).

Among the many Minnesota alumni who have made distinguished contributions to medical education, it is fair to say that Dr.

Dr. Carlyle F. Jacobsen, President
State University of New York, Upstate Medical Center

To help dispel the symptoms
of mild depressive states

CONSIDER **DEXAMYL**® FIRST
brand of dextroamphetamine sulfate and amobarbital

Often within the hour, 'Dexamyl' works to help dispel such symptoms as apathy, pessimism, loss of interest and initiative, and lack of ability to concentrate.

Formulas: Each 'Dexamyl' Spansule® capsule (brand of sustained release capsule) No. 1 contains 10 mg. of Dexedrine® (brand of dextroamphetamine sulfate) and 1 gr. of amobarbital, derivative of barbituric acid [Warning, may be habit forming]. Each 'Dexamyl' *Spansule* capsule No. 2 contains 15 mg. of Dexedrine (brand of dextroamphetamine sulfate) and 1½ gr. of amobarbital [Warning, may be habit forming].

The following is a brief precautionary statement. Before prescribing, the physician should be familiar with the complete prescribing information in SK&F literature or *PDR*.

Precautions: Use with caution in patients hypersensitive to sympathomimetics or barbiturates and in coronary or cardiovascular disease or severe hypertension. Do not use in patients taking MAO inhibitors. Excessive use of the amphetamines by unstable individuals may result in a psychological dependence; in these instances, withdraw the medication. Use cautiously in pregnant patients, especially in the first trimester. *Side effects:* Insomnia, excitability and increased motor activity are infrequent and ordinarily mild.

SK&F SMITH KLINE & FRENCH LABORATORIES

Jacobsen ranks in the top group. His contributions extend far beyond the confines of this Center.

Perhaps the pervasive characteristics of Dr. Jacobsen's diversified career contributions have been those of architect, planner, and builder. These attributes were evident early in his scientific work. Following his graduation from the University of Minnesota his design and planning abilities were devoted to the development of novel learning tests for primates. He went on to work with the distinguished physiological psychologist Lashley at Chicago where he began his classic studies on the functional architecture of the cerebral cortex. This work was continued and extended by joining the late Professor John F. Fulton's group in neurophysiology at Yale during its halcyon* period of the thirties. This work formed some of the basis for the neuropsychology which has developed lately (on a recent visit to the Soviet Union it was found that the workers in the primate laboratory at the Pavlovian Institute were thoroughly familiar with "Jacobsen's work.")

It was reasonable to expect, therefore, that when Dr. John Whitehorn went to Washington University in St. Louis in the late thirties to develop a department of psychiatry, one of his first appointments would be Carlyle Jacobsen as professor of medical psychology. In addition to his teaching and research assignments his psychological background was applied to the problems of medical school selection, and through his talents for design he subsequently became one of the architects of the Medical College Admissions Test. His planning abilities were recognized more and more, and with the coming of World War II he was increasingly involved in medical school and university administration. In 1946 he accepted an invitation from the University of Iowa to become a Dean of the Graduate School and later assumed the post of Executive Dean of the Division of Health Sciences and Services.

But perhaps his greatest contributions to medical and to higher education have been made since he joined the State University of New York. In 1950, just after the State University had been established (in a State which had a tradition of strong private universities and no state university — something difficult for a mid-westerner to fathom), Dr. Jacobsen's appointment to the central staff of the new State University as Executive Dean for Medical Education was indeed fortunate. For in addition to his personal capacities, his background in two strong state universities and two private universities provided an appropriate blend from which to begin to plan. Because of his widely ranging interests and his presence in the central office of the University, his influence was felt on the development of the total University and not exclusively on that of the Medical Centers. The continued growth of the University is in no small measure a reflection of his influence on the early evolution of the educational policy and program.

By 1957 the development of the Downstate and Upstate Medical Centers under Dr. Jacobsen's jurisdiction had progressed to the point where greater autonomy for each of the Centers (and other units in the University) seemed desirable, and the position of Executive Dean was therefore eliminated. Dr. Jacobsen continued his leadership as President and Dean of the Upstate Medical Center from 1957 to 1965; in 1965 he relinquished the deanship in order to devote his full attention to the expanding responsibilities of the President's office.

From the accomplishments at the Upstate Medical Center the diversified talents of Dr. Jacobsen as educator, administrator, and builder are most apparent. The period under his leadership has been one of rapid growth of physical plant, of educational programs, and of faculty strength. The number of medical school graduates has approximately doubled, and his interest in the allied health professions has been manifested in an increased graduate student enrollment and the establishment of innovative educational programs in nursing, medical technology, and x-ray technology. The educational bud-

Frankly, most antihypertensives are pretty good if you give an adequate dose. I'm looking for one with a simple regimen so that mix-ups in doses and therefore the chance of side effects are minimized.

Regroton®

chlorthalidone 50 mg. reserpine 0.25 mg.

1 tablet daily
brings pressure down

Advantage: Both components of Regroton are long-acting.
Average dosage: One tablet daily with breakfast.
Contraindications: History of mental depression, hypersensitivity, and most cases of severe renal or hepatic diseases.
Warning: Discontinue 2 weeks before general anesthesia, 1 week before electroshock therapy, and if depression or peptic ulcer occurs. With administration of enteric-coated potassium supplements, the possibility of small bowel lesions should be kept in mind.
Precautions: Reduce dosage of concomitant antihypertensive agents by one-half. Discontinue if the BUN rises or liver dysfunction is aggravated. Electrolyte imbalance and potassium depletion may occur; take particular care in cirrhosis or severe ischemic heart disease and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended. Use with caution in patients with ulcerative colitis, gallstones, or bronchial asthma.
Side effects: Nausea, vomiting, diarrhea, muscle cramps, headaches and dizziness. Potential side effects include angina pectoris, anxiety, depression, drowsiness, hyperglycemia, hyperuricemia, lassitude, leukopenia, nasal stuffiness, nightmare, purpura, urticaria, and weakness.
For full details, see the complete prescribing information.
Availability: Bottles of 100 and 1000 tablets.

Geigy

get has increased approximately ten-fold. Cardinal to this rapid development has been the recruitment of a faculty with a wholesome balance among investigative, teaching, and patient-care responsibilities.

The physical plant has been expanded to meet the increasing demands of the educational, research, and service programs. In 1957 an addition to the basic science building more than doubled the space for the basic science departments. In July 1964, a new outpatient wing of the new teaching and research hospital was opened; in July 1965, the 360-bed University Hospital (at a cost of approximately 25 million dollars), including new research laboratories for the clinical departments of the faculty, was opened. Two new student dormitories have been added to the Center's complex, and ground was broken this summer for a Student Activities Building.

On the national scene Dr. Jacobsen's counsel has been sought by foundations and public agencies. He served as Executive Vice Chairman of the Ford Foundation's Medical School Grants Committee as well as on the Surgeon General's Committee on Medical School Grants and Finances. He also served the National Foundation for Infantile Paralysis in various capacities from 1949 to 1961. His role as an innovator was recognized by the National Institutes of Health by his appointment to the initial National Advisory Council on Health Research Facilities and subsequently to the initial National Advisory Council on the General Medical Sciences. He has served on National Research Council Committees and on various committees of the Association of American Medical Colleges. He acted as co-chairman of the AAMC Teaching Institute on Medical Services and Medical Education — Today and Tomorrow. He is frequently consulted by various agencies and institutions for guidance in meeting needs in health manpower.

We could go on elaborating the accomplishments of a psychologist who has served as one of the architects of modern medical education. But in a sense it would be carrying coals to Newcastle, for the University of Minnesota has already bestowed on Carlyle F. Jacobsen its Outstanding Achievement Medal.

Julius B. Richmond, M.D.
Dean, The Medical Faculty
State University of New York
Upstate Medical Center

New York Upstate Medical Center

MINNESOTA MEDICINE is privileged to publish in this issue a group of articles from the Upstate Medical Center of Syracuse, New York. Dr. Julius Richmond, Dean of the Medical School, pays tribute to the University of Minnesota, the Alma Mater of Dr. Carlyle F. Jacobsen, President of the State University of New York, Upstate Medical Center in Syracuse. The University of Minnesota, he points out, has already paid its tribute to Dr. Jacobsen by awarding him its Outstanding Achievement Medal in 1951.

Minnesota physicians will take vicarious pride in reading of the career of this Minnesota psychologist, a career which includes the deanship of a great medical school.

Another former Minnesotan contributing to this "Upstate Medical Center" issue of MINNESOTA MEDICINE is Gordon Moe, M.D., Ph.D. in physiology, University of Minnesota, 1940. Many Minnesotans will recall that in 1958 Dr. Moe was also given the University of Minnesota's Outstanding Achievement Award.

Syracuse, like Minnesota, is the beneficiary of Masonic support of medical research.

MINNESOTA MEDICINE welcomes contributions from other states as single articles of general medical interest, as symposia, or as in this issue, a group of articles from an outstanding institution. We thank the contributors from Syracuse, and say to them, misquoting Shakespeare: "Physicians of Syracusa say no more; it hath in solemn synods been decreed, both by Syracusians and ourselves to honour each the other in our adverse towns."

Reuben Berman, M.D.
Minneapolis, Minnesota

SQUIBB NOTES ON THERAPY

Breast-feeding and the "modern mother"

Despite a mild resurgence of interest in the importance of breast-feeding a few years ago, many women today do not choose to nurse their young. This is for a variety of reasons—social, economic, cultural and sometimes medical. In such cases the physician's task is to find the most suitable means of preventing lactation and easing the pain of breast engorgement.

The means of therapy

The value of hormone therapy for this indication is of course well established. Both androgen and estrogen are known to inhibit the production and secretion of the lactogenic hormone by the anterior pituitary. As estrogen levels decline sharply at parturition, lactogenesis is established. When androgen and estrogen are administered to the patient before the release of the lactogenic hormone lactation and breast engorgement are usually prevented.

The time of therapy

The time of administration of this combined medication is crucial; it must be given early enough to suppress the pituitary prolactin and last long enough to permit physiologic readjustment during the puerperium. Excellent results are most often seen when therapy is administered before the onset of the second stage of labor.

However, factors other than effectiveness must also be considered. The agent selected should not interfere in any way with parturition, subsequent uterine involution and the restoration of normal ovarian cyclic function. Furthermore, it should not cause rebound breast engorgement or other manifestations of hormonal imbalance.

A balanced formulation

Providing single-dose therapy for the prevention of lactation and breast engorgement, Deladumone OB is a potent androgen-estrogen combination with a prolonged action. The optimal balance of androgenic and estrogenic hormones achieved in this preparation minimizes the disadvantages inherent in single hormone therapy, such as rebound breast engorgement. Involution of the uterus and resumption of menstrual cycles are not affected.

As reported in a recent published study (Roser, D. M.: Obstet. & Gynec. *27*:73, 1966), Deladumone OB provided good suppression of breast engorgement in 95.3% and suppression of lactation in 81.1% of 86 obstetrical patients. These results are in general agreement with those of many earlier investigations; in several studies this injectable androgen-estrogen combination proved to be superior to oral medication.

Dosage:

As a single injection of 2 cc. before the onset of the second stage of labor.

Contraindications:

Established or suspected mammary cancer or genital malignancy.

Precautions and Side Effects:

Certain patients may be unusually responsive to either estrogenic or androgenic therapy. In such individuals virilization, uterine bleeding or mastodynia may occur.

Supply:

Deladumone OB, providing 180 mg. testosterone enanthate and 8 mg. estradiol valerate per cc., is available in 2 cc. Unimatic® disposable syringes and in 2 cc. vials. Both preparations are dissolved in sesame oil, with 2% benzyl alcohol as a preservative. *Before use, consult product literature for full prescribing information.*

Deladumone® OB

Squibb Testosterone Enanthate (180 mg./cc.)
and Estradiol Valerate (8 mg./cc.)
Single-dose injection for lactation inhibition

SQUIBB *'The Priceless Ingredient' of every product is the honor and integrity of its maker.*

What Are We Doing in This Joint?

THE SURGERY of arthritis is the surgery of joints. Any surgeon who approaches the problem must accept the fact that rheumatoid arthritis in particular is primarily a generalized disease involving connective tissue and that joint impairment is a secondary manifestation. However, it is the joint symptoms that bring the patient to the physician and it is the joints that offer themselves for palliative or corrective procedures.

"To bend or not to bend" is a recurring question when considering the surgical approach to an arthritic joint. Such joints were made to bend originally and the ideal is to restore a damaged articulation as nearly as possible to normal. But the original models were also made to bend painlessly in a predictable direction and to provide a stable fulcrum over which the muscles could work. Can these features be restored?

As with the rest of medicine there is no perfect solution, but in individual cases there is usually an acceptable compromise. In the past the tendency has been toward arthrodesis to eliminate pain and provide stability. The list of authors and techniques for fusing each joint is long and reads like a "Who's Who" of orthopedic surgery. Emphasis has tended to shift gradually toward arthroplasty with the aim being to reduce pain while maintaining or restoring motion and preserving stability. This has been attacked with creative ingenuity and an astonishing supply of metallic gadgetry, with substantial but not uniform success. Failures at this stage have prompted a more aggressive approach advocating surgical intervention before the joint begins to lose the basic components of function. Synovectomy, osteotomy for joint realignment, tendon reposition or transfer — all have been designed to minimize or delay joint deterioration. In these cases the surgeon must derive his satisfaction from a technical job well done and a conviction that his patient will be spared future trouble. The patient himself is rarely exuberant when he is persuaded to undergo an operation before symptoms make it an obvious necessity.

There is no operation yet devised which can completely prevent progression of disease or return a destroyed joint to a normal condition. The primary goal is usually prevention of pain or pain relief; but in the case of multiple major joint involvement, maintenance of motion may be an overriding consideration. Where to start and when to stop are frequently imposing problems when dealing with the rheumatoid arthritic: the first often determined by the surgeon's fancy, the second by the patient's endurance. At best surgery is only a partial answer; but as increased understanding of the mechanisms behind arthritis should begin to eliminate the crippling end result, so should improved knowledge of the physiology and mechanics of articulations eventually make it possible to approach the devastated joint with a confident appraisal of "what we are doing there."

David G. Murray, M.D.*
Syracuse, New York

Phrenic Nerve at the Esophageal Hiatus

AS DOCOTORS KLETSCHKA and Wynyard* have pointed out, the finer details of the distribution of the phrenic nerves to the diaphragmatic musculature have received scant consideration in the commonly used anatomical texts. This applies especially to the terminal distribution of the posterior divisions of the phrenic nerves as they course on and in the substance of the crura adjacent to the esophageal hiatus.

spasm of the

'G. I.' tract.

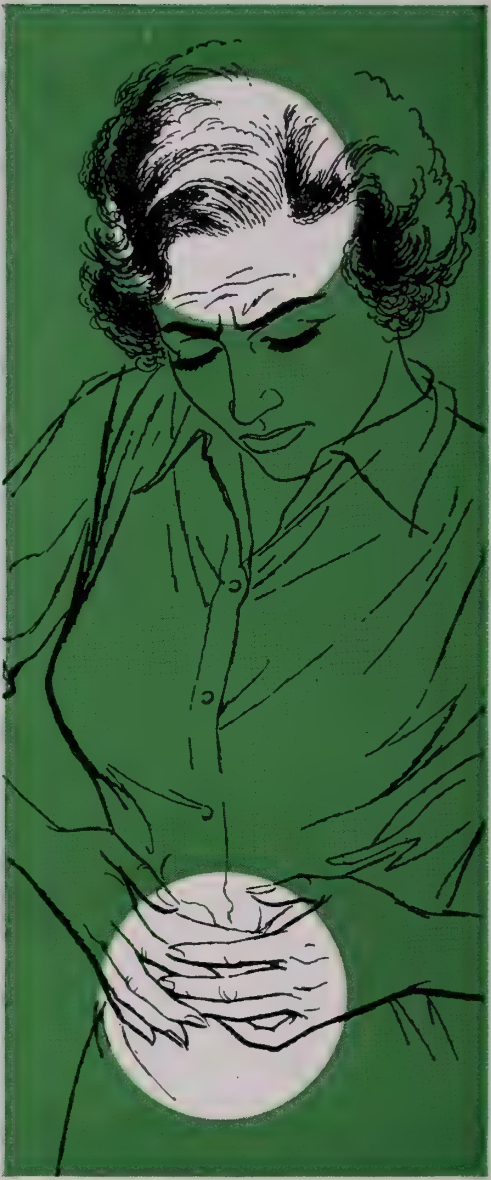
Butadonna®

BUTABARBITAL SODIUM 15 MG. (BARBITURIC ACID DERIVATIVE)
WARNING: MAY BE HABIT FORMING
BELLADONNA EXTRACT (TOTAL ALKALOIDS [illegible]), 15 MG.

provides gentle,

intermediate sedation and

relaxes 'G. I.' spasm.



Butadonna quiets the "brain-on-gut" influences by providing the smooth, intermediate sedative, butabarbital sodium, desirable in combination with the proven antispasmodic, belladonna extract. Butabarbital sodium is more rapidly eliminated than phenobarbital, and avoids the latter's cumulative effect.

Indications: Antispasmodic-sedative. Useful in the treatment of peptic ulcer, gastritis, duodenitis, irritable colon syndrome, ulcerative colitis, regional enteritis, and other conditions associated with gastrointestinal spasm. Also may be useful in functional dysmenorrhea.

Usual adult dosage is one tablet 3 or 4 times daily as needed.

Caution: Contraindicated in glaucoma and urinary retention. Reduce dosage or discontinue use in event of blurring of vision, dryness of mouth, tachycardia, or excessive drowsiness. Continued use of butabarbital sodium may be habit forming.

Cole

COLE PHARMACAL COMPANY, INC.

3721 Laclede Avenue • St. Louis, Missouri 63108

The present study confirms the findings of Collis et al.,[1] and of Botha,[3] and has added other detail as to the relationship of the phrenic nerves to the margin of the hiatus in their course. Of more importance is their consideration and emphasis on the terminal course of the nerves to the crura when dealing with the surgical aspects of hiatus hernia repair and the control of gastric reflux. Accurate knowledge of the anatomical relationships facilitates surgical intervention and repair in the region and the retention of the normal physiological activities of adjacent structures encountered.

An analysis of these anatomical arrangements, which may be found bounding the esophageal hiatus,[2] leads to certain deductions as to the action of the muscle surrounding the hiatus on the esophagus and the cardiac notch. Although these deductions appear to be logical ones, there is a lack of experimental proof of the relative importance of the cardiac valve, cardiac notch and the hiatal musculature in physiological control of the opening into the stomach in the living state.

The details presented in the current study and in the others cited could be utilized to devise suitable experiments which would demonstrate the independent or concerted action of these parts in exercising control over this area. With such knowledge at hand, surgical procedures would be designed with greater assurance of success in alleviation of gastric reflux.

Violent Behavior Associated with Brain Tumor

> And earthly power doth then show likest God's
> When mercy seasons justice. — Shakespeare

DR. ARTHUR ECKER,* in presenting the clinical pathological conference, discusses in a very instructive way the interesting account of a patient with a brain tumor exhibiting behavioral aberrations. Such cases can represent baffling and challenging diagnostic problems. Dr. Ecker's precise and methodical analysis of the psychiatric and neurologic aspects of the case in arriving at the proper diagnosis is, therefore, worthy of careful review and study.

Controversy continues to be waged as to the causal relationship of behavioral changes occurring in patients with coexistent brain tumor. Public interest recently focused on this association following the mass killings in Austin, Texas. Charles Whitman, the slayer, had sought prior psychiatric help, and at autopsy was found to have a malignant brain tumor. Was the brain tumor responsible for his personality disorder? Or did the brain tumor only incidentally develop in a young man already afflicted with a preexistent character disorder? Judging by the widespread reporting and discussion surrounding this case it appears that society has a practical interest in the answers to those questions.

It is frequently pointed out in the medical literature that "psychiatric" patients are not more likely to develop brain tumors than those from the general population. But it is also important to stress that the incidence of brain tumor among patients in mental hospitals is three and one-half times that found among the general population.

That early behavioral changes associated with brain tumor are not unusual is shown in a paper by Strauss and Keschner.[1] They

in chronic illness

B and C vitamins are part of therapy: An imbalance of water-soluble vitamins and chronic illness often go hand in hand. STRESSCAPS capsules, containing therapeutic quantities of vitamins B and C, are formulated to meet the increased metabolic demands of patients with physiologic stress. In chronic illness, as with many stress conditions, STRESSCAPS vitamins are therapy.

STRESSCAPS

Stresscaps®

Stress Formula Vitamins Lederle

FOR PROFESSIONAL RECOMMENDATION ONLY

Each capsule contains:

Vitamin B_1 (as Thiamine Mononitrate)	10 mg
Vitamin B_2 (Riboflavin)	10 mg
Vitamin B_6 (Pyridoxine HCl)	2 mg
Vitamin B_{12} Crystalline	4 mcgm
Vitamin C (Ascorbic Acid)	300 mg
Niacinamide	100 mg
Calcium Pantothenate	20 mg

Recommended intake: Adults, 1 capsule daily, for the treatment of vitamin deficiencies. Supplied in decorative "reminder" jars of 30 and 100; bottles of 500.

LEDERLE LABORATORIES, A Division of American Cyanamid Company, Pearl River, New York

Lederle

628-6—3614

found that mental symptoms were the earliest manifestations in 43% and changes in personality in 30% of frontal lobe tumors, and in tumors of the temporal lobe in 35% and 23% respectively. Behavioral aberrations associated with brain tumor take on a violent character in a high percentage of cases. Henry[2] observed that suicidal tendencies occurred in about 10%. The case discussed by Dr. Ecker was one in which violent behavior was associated with an acoustic neurinoma. Rubert and Remington[3] reported on 34 patients exhibiting psychoses due to brain tumor with violent behavior being recorded in 8 (assaultive behavior in 5 and suicidal attempts in 3) or 23.5%.

That there is a cause and effect relationship between intracranial tumors and associated behavioral changes is strongly suggested, not only by the higher incidence of such personality disturbances among brain tumor patients as opposed to the general population, but by the fact that such abnormal symptoms may disappear after successful removal of a coexisting brain tumor.[4,5]

It is, therefore, apparent that a substantial body of evidence exists supporting the belief that intracranial neoplasms can directly result in bizarre psychiatric manifestations which often take on an expression of violence. One would hardly draw this conclusion, however, from a review of the articles and commentaries which have appeared covering the story of Charles Whitman. Expressions published in the national popular news media[6,7,8,9,10,11] almost universally dissociated the deranged behavior he exhibited from the brain tumor which he harbored.

In strict justice, expert medical opinion must be objective in reporting to society. Society will rely on such information to develop preventive and other programs to cope with the social problems attending such crimes. Society will also rely on such information in passing judgment on the offender. In the case of Charles Whitman it would seem that medical evidence would support a more benevolent judgment than that which he has been accorded.

BLUE SHIELD
OF MINNESOTA ®

You May Be Right

Each year, a statement of dues owed for membership in the Hennepin County, Minnesota State and American Medical Associations is mailed to the members. Frequently, as this year, the amount increased substantially.

Many doctors, faced with increasing society dues, coupled with a public image which has become steadily worse, wonder how much more political activity we are expected to pay for and, having paid for, suffer for.

I would like to hear reaction from other physicians. A poll to determine the position of a large group on dues, what is done with them, and to offer guidance, might be undertaken, if agreeable, by MINNESOTA MEDICINE.

The executive secretaries of the societies involved could be invited to set forth an account of their funds received and expended. If we can replace random criticism with a study of attitudes and an explanation of society activities, it will be a constructive step.

The Editor's Soliloquy

Convention Report

I suppose I should report on my visit to the Medical Meeting in San Francisco and incidentally mention my expense account. I took my wife along. How she can spot a chic and exclusive shopping center blocks and blocks away is amazing! She seems to have a sort of sixth sense in that direction. Like a thoroughbred she puts her nose up wind and proceeds briskly and confidently by the shortest route to Sak's Fifth Avenue, Bergdorf's, or Van Clief and Arpelt — in any city.

Well, she bought an elegant pair of 8½ quads brown with black toes, an equally elegant leather purse, and a pair of gloves to match. After that handsome purchase we boarded the squealing, screeching cable car for a ride to famous Fisherman's Wharf, where we invested 10 cents on a telescopic look at The Rock, and just barely got it focussed when it clicked off. Then we ambled casually over to take a look at Di Maggio's but found it much too expensive for a couple of Minnesotans on a sparse diet. So, after wandering about a bit longer absorbing the exotic aura of the Wharf: its unique aggregate of sights, sounds, and smells, we caught the cable car back to town. Returning to the Hilton, we bought a package of licorice and then went up to our room for our noonday siesta.

Total expenditure for one morning's ramble:	Cable car	,30
	Telescope	.10
	Licorice	.10
	Total	.50
Oh, I forgot shoes and purse and gloves ensemble:		134.50
	Tax	4.03
	New Total	139.03

Julius B. Richmond, M.D.
Dean, The Medical Faculty

The future of any medical school rests with the direction and stimulus given to its development through its academic leadership. In 1965 Dr. Julius Richmond was appointed Dean of the Upstate Medical Center and under his able guidance the growth of the Center is anticipated with unbounded confidence.

In 1953 Dr. Richmond left his post as Professor of Pediatrics at the University of Illinois to assume the position of Professor and Chairman, Department of Pediatrics at the Upstate Medical Center. He continues to function in this capacity in addition to carrying on his many other important diverse duties and responsibilities.

As a clinician he has gained worldwide renown in the field of Pediatrics. He has expanded the dimensions of Pediatrics bearing on child problems

Continued

of all types. He has created a new model for the role of the pediatrician by emphasizing concern for the child as an entity with his own unique biological, environmental, and social problems.

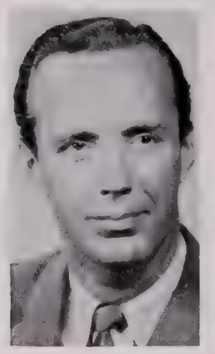
Outstanding scholarly and research contributions on his part span almost the entire spectrum of problems encountered in the field of Pediatrics and Child Welfare. Recognition has been accorded him for his conspicuous achievements by his being selected to hold many important offices in national medical societies. He exercises an important influence on the international medical scene as a member of the Expert Committee on Maternal and Child Health of the World Health Organization. For his distinguished contributions in the field of child development he was awarded the C. Anderson Aldrich Award in 1966.

Dr. Richmond brought great honor to the Upstate Medical Center in 1965 when he was appointed National Director of Project Head Start. Selection for this position is undoubtedly a reflection of his deep sense of social commitment. Mrs. Lyndon B. Johnson has identified herself with this program as one in which she has a special personal interest. On an occasion recognizing Dr. Richmond's contributions the First Lady saluted him saying, "Dr. Richmond is one of the most important commuters in Government." This remark gives insight into the importance of the program and suggests the taxing time commitments and activity of this demanding position.

Despite the enviable reputation he has achieved in his tripartite role as administrator, clinician, and civic leader, Dr. Richmond jealously guards his identity as a pediatrician.

Alfred S. Berne, M.D.

Dr. Alfred Berne was born in New York and received his M.D. degree from Duke in 1946. Following an internship in Chicago he took his residency training at Presbyterian Hospital in New York City. After serving on the faculty of the Department of Radiology at Columbia he came to Syracuse. He is currently Professor of Radiology at the Upstate Medical Center and is Chief of the Department of Radiology at Memorial Hospital, Syracuse.



David M. Connelly, M.D.

Dr. David Connelly graduated from the Temple University School of Medicine in 1954. He received his general surgical training at Memorial Hospital in Wilmington and with the U. S. Air Force. He continued his graduate training in Plastic and Reconstructive Surgery at Duke University and New York Hospital — Cornell Medical Center. Currently he is Instructor in Surgery (plastic) with the Division of Maxillofacial and Plastic Surgery at the Upstate Medical Center.

Dr. Arthur Ecker was born in New York City and graduated from Johns Hospkins Medical School in 1934. He was a Fellow in Neurology and Neurosurgery at the Mayo Clinic from 1935-39, during which time he was awarded the M.S. and Ph.D. degrees in Neurology from the University of Minnesota. He served as Clinical Professor of Surgery (Neurosurgery) at the Upstate Medical Center from 1955-63 and is now engaged in the practice of neurosurgery in Syracuse.

Arthur D. Ecker, M.D.

Dr. Daniel Elstein was born in New York City and received his M.D. degree from the Downstate Medical Center in 1958. He completed his internship and general surgery training at Montefiore Hospital. He then took his orthopedic surgery postgraduate work at the Memphis Veterans Hospital and Upstate Medical Center. Currently he is Clinical Instructor in Orthopedic Surgery at the Upstate Medical Center and Assistant Chief of Orthopedic Surgery at the Veterans Hospital in Syracuse.

Daniel Elstein, M.D.

Dr. Robert Gregg was born in New York and graduated from Syracuse University Medical School in 1934. Following his internship in Syracuse he took a Fellowship at the Mayo Clinic and received an M.S. degree in Surgery from the University of Minnesota in 1939. During his time spent at the Mayo Clinic he served as Assistant to Dr. Claude F. Dixon from 1939-40. From 1953-56 he was Chairman of the Department of Surgery at the Upstate Medical Center where he continues to serve as Professor of Surgery. He has gained distinction in the field of arterial surgery.

Robert O. Gregg, M.D.

Dr. Warner Hammond was born in Washington, D. C., and took his postgraduate training at Cornell, where he received his Ph.D. in Anatomy in 1937. He has been on the faculty of the Medical School in Syracuse since that time. At present he is Associate Professor of Anatomy at the Upstate Medical Center.

Warner S. Hammond, Ph.D.

E. Robert Heitzman, M.D.

Dr. E. Robert Heitzman was born in Syracuse and graduated from the New York State College of Medicine at Syracuse in 1951. He received his graduate training as a Fellow in Radiology at the University of Minnesota Hospitals from 1952-55. At the present time he is Associate Professor in the Department of Radiology and Director of the Division of Diagnostic Radiology at the Upstate Medical Center.

Harold D. Kletschka, M.D.

Dr. Harold Kletschka was born in Minneapolis and graduated from the University of Minnesota Medical School in 1947. He received his general and thoracic surgical training at the University of Michigan and the Downstate Medical Center. At the present time he is the U. S. Air Force Medical Service Liaison Officer and Assistant Professor of Surgery at the Upstate Medical Center. In addition, he is Chief of the Section of Thoracic Surgery at the Veterans Hospital in Syracuse.

Gordon K. Moe, M.D., Ph.D.

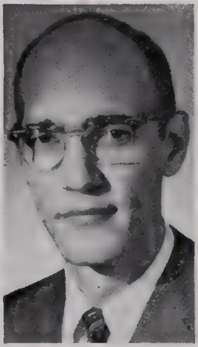
Dr. Gordon K. Moe attended the University of Minnesota Medical and Graduate Schools from 1934 to 1940, during which time he received the B.S., M.S., and Ph.D. (Physiology) degrees. He obtained his M.D. degree from Harvard in 1943. After leaving the University of Minnesota he became associated successively with Western Reserve, Harvard, Michigan, and the upstate Medical Center in Syracuse. He was the Chairman of the Department of Physiology at the Upstate Medical Center from 1950 to 1960, at which time he became Director of Research at the Masonic Medical Research Laboratory. He continues to serve as Research Professor of Physiology at the Upstate Medical Center. In 1958 he received an Outstanding Achievement Award from the University of Minnesota.

David G. Murray, M.D.

Dr. David Murray was born in Iowa and was granted the M.D. degree from Washington University in 1955. Following an internship at Vancouver General Hospital he took surgical training at the Upstate Medical Center and completed his postgraduate work in Orthopedic Surgery at the State University of Iowa. He is presently Associate Professor of Orthopedic Surgery and Chairman of the Department of Orthopedic Surgery at the Upstate Medical Center.

Irwin H. Pizer, M.S.

Mr. Irwin Pizer was born in Willington, New Zealand. He obtained an M.S. degree from Columbia University in 1960. His positions in the Upstate Medical Center are those of Associate Professor of Medical History and Director of the Library.



David B. Robinson, M.D.

Dr. David Robinson was born in Pennsylvania and received his M.D. degree from the University of Pennsylvania. Following an internship and medical residency at Geisinger Memorial Hospital he continued his graduate training at the Mayo Clinic from 1951-56, receiving his M.S. degree (Psychiatry) in 1957. He came to Syracuse in 1958, and since January, 1964, he has been Associate Professor and Acting Chairman of the Department of Psychiatry at the Upstate Medical Center.

J. Albert Schaefer, M.D.

Dr. J. Albert Schaefer was born in New York and graduated from the Long Island College of Medicine in 1948. He took his graduate training at Western Reserve and the Crile Veterans Administration Hospital. At present he is Associate Professor of Pathology at the Upstate Medical Center and Chief of Laboratory Services at the Veterans Hospital in Syracuse.

David B. Stark, M.D.

Dr. David Stark was born in Canada and received his medical degree from Toronto in 1943. He obtained his graduate training as a Fellow in General Surgery and Oral and Plastic Surgery at the Mayo Clinic from 1946-51. He received an M.Sc. degree in surgery from the University of Minnesota in 1948. He is now Clinical Professor of Surgery (plastic) and Chairman of the Division of Maxillofacial and Plastic Surgery at the Upstate Medical Center.

Martin Wynyard, M.D.

Dr. Martin Wynyard was born in Germany, received his medical degree from London University in 1949, and obtained his Fellowship from the Royal College of Surgeons (England) in 1953. He obtained his general and thoracic surgical training at some of the world's leading medical centers in Great Britain and continued his training in this country at Lahey Clinic and the Upstate Medical Center. At the present time he is carrying out cardiovascular surgical research at the Veterans Hospital in Syracuse and is engaged in the practice of thoracic and cardiovascular surgery.

Parinaud's Oculoglandular Syndrome

Synonyms: *Parinaud's conjunctivoadenitis syndrome; cat-scratch-oculoglandular syndrome.*

Conjunctivitis, retrotarsal conjunctival granulations, regional preauricular and cervical lymphadenitis, and fever characterize this syndrome. It was first described by Parinaud (1889); Gifford suggested the eponymic designation (1898).

Clinically the condition may be recognized by the appearance of a granular and sometimes ulcerative conjunctivitis and early swelling of the anterior cervical and parotid glands. Other local tissues, such as the cornea, are not involved. A moderate febrile reaction accompanies the infection. It is almost invariably unilateral. The etiology has long been puzzling. Transmission from patient to patient does not seem to occur. Among the suspected causative agents are tularemia, leptothrix, sporotrichosis, lymphogranuloma venereum, and a yeastlike organism. An intradermal test with an antigen of cat-scratch fever frequently gives a positive reaction. Increasingly, Parinaud's oculoglandular syndrome and cat-scratch syndrome are regarded as having a common etiology, the conjunctivae being considered the site of primary infection. Spontaneous recovery occurs but may require a few weeks or a few months.

Durham, Robert H. — Encyclopedia of Medical Syndromes
Hoeber Medical Division, Harper and Row, New York

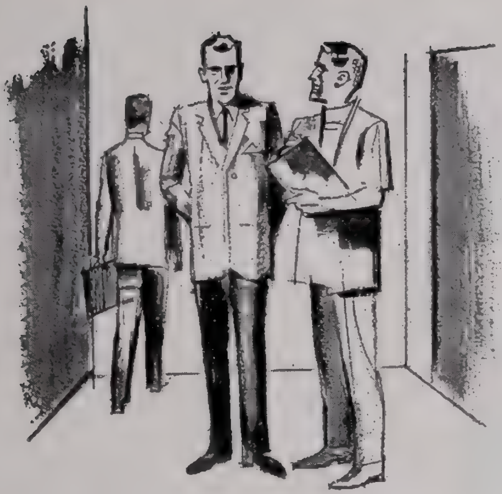
As for style of writing, if one has anything to say; it drops from him simply and directly, as a stone falls to the ground. . . . A sentence should read as if its author, had he held a plough instead of a pen, could have drawn a furrow deep and straight to the end.

Thoreau Letters

Three things cannot be taught — generosity, poetry and a singing voice.

— Irish proverb

When a thing is funny, search it for a hidden truth. — George Bernard Shaw



Curbstone Consultation

Respiratory Tract

Question: What is the relative incidence of cancer of the respiratory tract in the male compared to the female?

Answer: It occurs about four or five times more frequently in the male, accounting for 18-20% of all cancer in that sex.

Harold D. Kletschka, M.D.
Syracuse, New York

Bronchogenic Carcinoma

Question: I have a patient with bronchogenic carcinoma and myasthenic-like syndrome. Does the existence of this latter manifestation mean that the patient's tumor is incurable?

Answer: About 15% of patients with bronchogenic carcinoma will exhibit neuromyopathic findings. The myopathic-myasthenic syndromes are the most common. It is felt that the myasthenic-like symptoms result from a defect in neuromuscular conduction and a polymyositis with primary degenerative changes in the muscles. The syndrome is characterized by weakness of the proximal muscles of the extremities, particularly the thighs, but does not in itself signify that the tumor should be considered incurable. As a matter of fact the symptoms may disappear following removal of the primary lung tumor. It is important to differentiate the symptoms encountered in such neuromyopathies from those of metastatic disease. Patients with this syndrome may experience a marked sensitivity to curare and depolarizing relaxants.

Harold D. Kletschka, M.D.
Syracuse, New York

Weightlessness of Manned Space Flight

Question: Has the weightlessness of manned space flight resulted in untoward cardiovascular changes?

Answer: Cardiovascular function is altered during manned space flight. However, it is difficult to assign such changes to a single environmental factor such as weightlessness. The changes observed are similar to those seen in cardiovascular deconditioning consisting of decreased exercise and orthostatic tolerance. Nevertheless, it appears that with currently available life support systems weightless flight can be tolerated for a period of at least one month.

The Viewing Box

A 39-YEAR-OLD female had been in the hospital, February 1965, with an acute exacerbation of rheumatoid arthritis. At that time the chest roentgenogram was negative. She had had rheumatoid arthritis for thirteen years. She had been treated with various steroid derivatives continuously over this period.

In late November she was admitted with episcleritis and the usual painful joint complaints but no chest complaints. An admission chest roentgenogram (Figures 1 and 2) disclosed a left pleural effusion with partial atelectasis of the left lower lobe and lingula of the left upper lobe. It was also felt that a partial left pneumothorax or multiple bleb formation was present. Cardiac fluoroscopy and an esophagram showed cardiac enlargement and elevation of the apex of the heart. Planigrams disclosed a mass density in the left lower lobe area. Bronchoscopy with followup bronchography (Figures 3 and 4) demonstrated elevation of the lingula of the left upper lobe and deviation and compression of the bronchi of the left lower lobe posteriorly. The mass causing this deviation appeared to contain a loculated air or bleb formation. Thoracentesis yielded only 2 cc. of fluid. Laboratory findings were within normal limits. The thoracentesis fluid culture revealed no growth.

What Is Your Diagnosis? (See next page.)

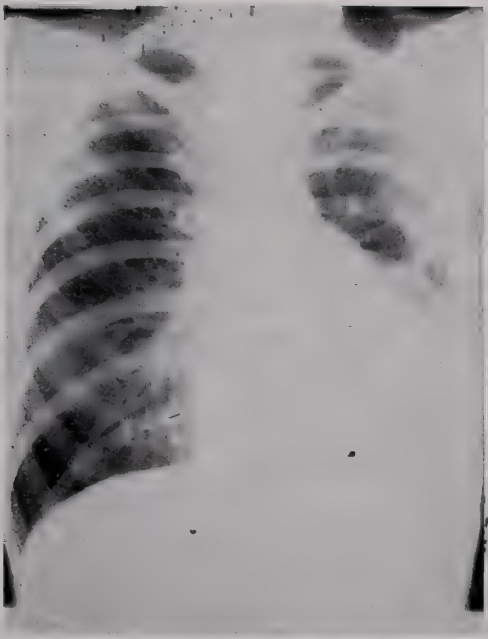

Figure 1

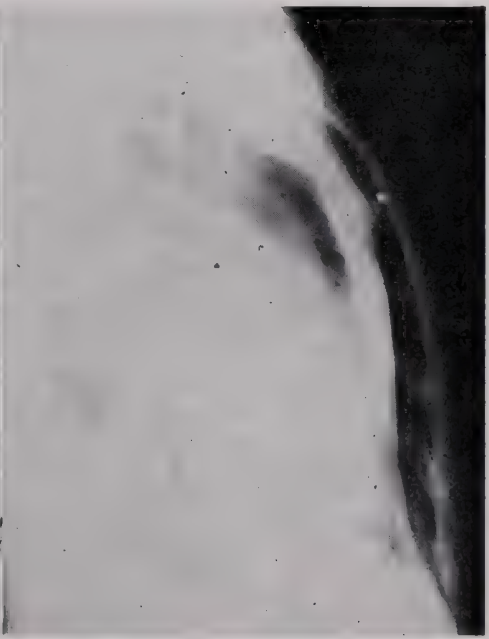

Figure 2

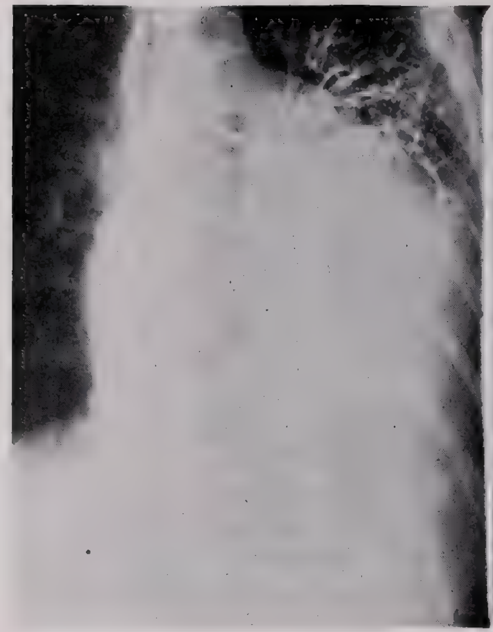

Figure 3

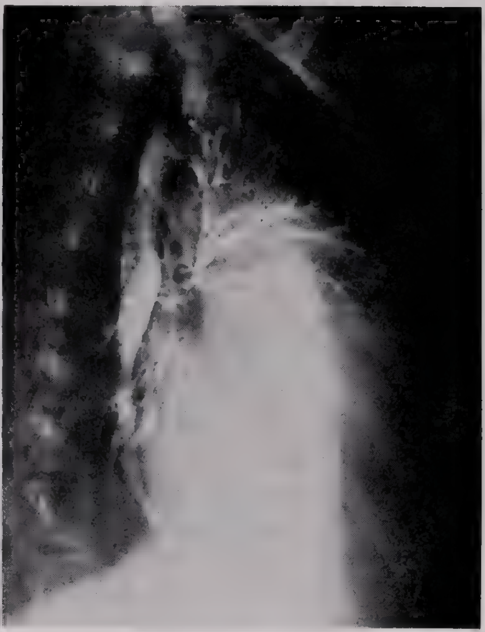

Figure 4

Diagnosis: Empyema.

The patient declined to have any further procedures and went home. One week later she was found dead in bed.

An autopsy was performed. The left pleural cavity contained a greenish-yellow thick loculated empyema of 500 cc. plus. The pleura was very thick and irregular with multiple adhesions and pockets including adhesions to the pericardium. The right lung weighed 325 grams and was unremarkable but the left lung weighed only 125 grams and was markedly compressed. The pericardium was thickened and pericarditis with thick fluid was present. Multiple small abscesses were found in the brain, heart, spleen and lymph nodes. The adrenal glands were atrophied. Special stains of these abscessed areas revealed no organisms. Cultures over a prolonged period of time revealed no growth.

The modern medical literature of today has scant reference to empyema. Not too many years ago empyema was a common diagnosis. In the present case a pneumonia, pleurisy, empyema and, finally, pyemia did occur but without the usual clinical manifestations. This does happen in the chronically debilitated patient, particularly when the prolonged use of steroid and antibiotic therapy has been necessary. Remember—empyema still does occur.

A man is really a success when flattery gives him a headache instead of a big head.
— Ralph Bellamy

Neurological Conference

Progressive Spastic Quadriplegia[*]

Doctor Ross Olson[**]

The patient is a 58-year-old former engineer who came to the University Hospitals for the first time in May, 1966. His chief complaints were a 10-day history of hemoptysis and an 11-year progressive spasticity of his extremities. The hemoptysis appeared acutely and was accompanied by right chest pain. He said that he had coughed up dark clots, followed by bright blood which had not appeared to be mixed with mucus. After continuing for some time, this seemed to subside. He had also noted that his stools were darker then. His family physician examined him at that time and took a chest x-ray which was negative; however, on laryngoscopy he found what he considered to be a tumor of the vocal cords.

Past History and Findings

The history of the spasticity began in 1955 when the patient first noticed that his left foot shook on the clutch as he was driving. Thereafter he had a gradual increasing difficulty in walking, and in the spring of 1956 he was referred to a neurologist.

Tenderness was found at the level of the T 10 vertebra and an erosion of that bone was present on the x-ray. An exploratory operation revealed a general constriction of the thoracic cord, which appeared to be a degenerative lesion rather than a tumor. One year later an electroencephalogram, cervical myelogram, and cervical tomograms were negative. Pneumoencephalography suggested a diffuse narrowing of the cervical cord but no evidence of tumor.

By 1958 he was using a cane, and within a short time he needed two. In 1958 his left eye suddenly became amaurotic.[†] Neurological consultation was obtained again at that time and it was thought the most likely cause was an embolic phenomenon. He has had no recovery of his vision

Continued

in that eye. In 1959 he spent two months in a private hospital in Denver, Colorado, where he obtained some subjective relief. They prescribed honey and fruit juice, which he still takes. Soon he was confined to a wheelchair and his company transferred him to a desk job. Involvement of his hands became more evident in 1960, and within one year he had to quit work entirely. Difficulty talking appeared in 1962 and trouble swallowing followed within the next two years.

In the past he has had no serious illness except what he called pleurisy in 1951. As a four-year-old child he had a back injury which was followed by opisthotonus for 24 hours, after which he apparently recovered completely. The presumptive diagnosis at that time was subarachnoid hemorrhage. He has smoked for 40 years, using as many as four packs a day at times. He currently smokes about one half to one pack a day, but in the very early part of his illness he was smoking up to four packs a day, since his gradual incapacitation in his work gave him more time for smoking. He was accustomed to an executive type position.

Physical Findings

On physical examination he appeared to be quite thin with a very tense face and looked quite old for 58 years. When he spoke he had an extremely severe dysarthria which made his speech virtually incoherent. His wife apparently could understand him and she would translate. His mental status was entirely intact. A left carotid bruit was noted and coarse rales were present in his lungs bilaterally. His blood pressure was 240/105 mm. Hg. and a grade ii/vi systolic ejection murmur could be heard at the apex of the heart. Moderate dependent ankle edema was present. Subjectively, no vision was present in the left eye, even to a flash light, and acuity in the right eye was slightly decreased. Funduscopic examination showed optic atrophy in the left eye and findings consistent with grade 2 to 3 hypertension in both fundi. He had generally hyperactive reflexes with positive toe signs, sustained clonus in the ankles which at times was spontaneous, a hyperactive jaw jerk, and positive palmomental reflexes. A generalized weakness of all muscles was present, especially in the hamstrings and adductors of the thighs. No obvious muscle atrophy was apparent.

Laboratory Data

Laboratory investigation showed a normal hemoglobin and white blood cell count. The erythrocyte sedimentation rate was 43 mm./hr. Urinalysis and a Schilling test were both negative. The cerebrospinal fluid showed a protein of 63 mg. %. Sputum culture revealed many gram-positive cocci in pairs, chains and clusters; there were also many diphtheroids and a few gram-negative rods. Electromyography showed evidence of denervation in the hamstrings and gastrocnemii. The chest x-ray revealed old apical pleural changes present bilaterally. Planograms of the right upper lobe of the chest showed pleural thickening of the right apex with some fibrotic strands extending into the parenchyma. There was also some calcification within this region. An upper gastrointestinal series, esophagram, and skull x-rays were normal. Cervical spine x-rays showed mild, degenerative changes. The disc spaces were fairly well preserved except for the C5 space, which showed some mild narrowing. At the C5 level there were some posterior spurs present. The Mantoux test was positive.

The Evaluation

Discussion with patient's wife.

Dr. Robert Soll* (to the patient's wife)

Do you have any special problems such as getting him in and out of bed or taking him to the bathroom?

Patient's wife

I let him do those things by himself. I got some strong luggage handles and fastened them to the head of the bed so he could hold on to them to roll over. He has a double bed because he would roll over and off the single bed that he had. Just recently we had to get a new toilet. He could put his hand on the tank of the old toilet which was fastened to the wall and then have braces up on the wall in order to transfer; however, I have just gotten those guards for the new toilet. They fit right over the side of it; so it was getting harder for him to turn from the wheelchair to the toilet.

Dr. Soll

Is there any problem with bathing?

Patient's wife

Our house is real old. He could get right up under the washbowl in the wheelchair; this wouldn't have been possible with a foot rest on his chair. He never wanted one because then he couldn't get up to things. He could wash himself in front; so I washed his back while he was sitting at the washbowl. He did his feet separately.

Dr. Soll

Has he ever choked or had trouble swallowing?

Patient's wife

He feeds himself and he does choke easily. I was afraid that this might happen when I was at work.

Dr. Soll

Do you know anything about the injury he had when he was four years old?

Patient's wife

All I know is that they lived on a farm in South Dakota. First of all he rolled off this load of cobs. I thought his mother had said that he hit a part of the wagon, but now he says that he hit the ground. He was semiparalyzed for 24 hours or so, and he couldn't lie down flat because he was bowed up according to his mother. I think his head and buttocks touched the bed but his shoulders didn't. The doctor thought it was spinal meningitis; so he had to send to Sioux City, Iowa, for serum, but when he came back the next day his patient was better. His mother said she alternated hot packs and cold packs on him all night long.

Dr. Frank Meelhuysen**

How much help does he need in dressing?

---

*Neurologist, University of Minnesota Hospitals.

**Assistant professor, Physical Medicine and Rehabilitation, University of Minnesota Hospitals.

Continued

Patient's wife

He does all his dressing, except that certain shirts give him a little difficulty.

Medical Evaluation

Dr. John Bergstrom*

This gentleman's presenting complaint and the reason he sought a doctor after being totally incapacitated for many years by a spastic disease was "spitting up blood," which apparently was not mixed with sputum. Significantly in the past he has been a heavy smoker, and, in addition, he has suffered from probable aspirations during the past two years. He has had decreasing amounts of sputum production in recent years; at one time he was bringing up quite a bit of orange-tinged sputum which has diminished with his decreased ability to cough.

A partially compensated paralysis of the left vocal cord was found. This means that the left vocal cord was immobile in the paramedian position; no evidence of a neoplastic process of the cords was found and the remainder of the ear, nose and throat examination was within normal limits. The chest x-rays taken at admission initially were read as negative for his age; however, on review of his films there was evidence of some fibrotic-appearing material in the right upper lobe. This was somewhat more apparent in the lordotic view of the apex. A similar finding had been reported in 1956. Our skin tests show a positive response for intermediate strength purified protein derivative (tuberculin).

There was a considerable degree of lability in his blood pressure ranging from about 180 to 220 mm. Hg. systolic and from 90 to 140 mm. Hg. diastolic. An intravenous pyelogram was obtained to rule out the possibility of renal disease. Although it was not a perfectly adequate study due to poor visualization of the nephrogram on the left, the excretion appeared to be equal and essentially normal. Examination of the urinary sediment was negative and the blood urea nitrogen was 11 mg. %.

Neurological Evaluation

Dr. Soll

It is interesting that this patient's past history includes a severe back injury. According to the history, he apparently developed opisthotonus, which would indicate a diffuse meningeal irritation. The general clinical picture and course of the disease on the other hand is suggestive of a pseudobulbar palsy and spastic quadriplegia. In this condition the involvement would be present in the corticospinal tract above the level of the medulla. The usual etiology is cerebral vascular disease but other degenerative conditions may also cause it.

In addition to difficulty walking, these patients demonstrate severe dysarthria and dysphagia, but our patient does not present altered emotional reactions such as are often seen in this condition. Eventually these patients develop difficulty from upper respiratory infections or may choke; however, they may survive many years if these complications are guarded against. The only evidence of lower motor neuron involvement below the level of the brain stem is the denervation potentials shown on the electromyogram of the lower extremity musculature.

---

*Medical fellow, University of Minnesota Hospitals.

Physical Medicine Evaluation

Dr. Meelhuysen

The patient is able to do his transfer activities independently at home, such as from bed to wheelchair and back, and from wheelchair to toilet. Of course, with the amount of spasticity he has, it requires considerable effort to make the transfer. Discrepancy between the height of the bed and his chair makes the transfer much more difficult for him. In addition, he can hardly stand because of the contractures in hips and knees, plus thigh adduction spasticity which causes crossing over of the legs. There is marked clonus in his ankles. Another feature apparent in this patient is his tight hamstrings, most likely due to spasticity and positioning of the legs. This contributes to his knee flexion contractures.

As far as joint range of motion in the upper extremities is concerned this is still in functional range. One usually sits with the arms internally rotated at the shoulders with pronated forearms and flexed elbows, a posture which becomes more evident when spasticity is present. In this patient there is already some limitation of external rotation in his shoulders and only 5-10 degrees of supination in his arms. In general his shoulder range is essentially normal for his age although he lacks about 30° flexion and abduction on both sides. There is clonus in the shoulder internal rotators, and the pectorals are spastic also. The latter can become so tight that the arm is continually kept in adduction. Both flexion and extension of the elbow demonstrate increased stretch reflex.

Another feature in this patient is the function of his tongue and its relationship to his dysarthria and dysphagia. He demonstrates marked weakness on tongue protrusion. Retraction and elevation of the tongue are important for moving a food bolus backwards. The former can be tested by retracting the tongue against manual resistance. The tip of the tongue is thereby held between the examiner's thumb and digits ii and iii while he exerts a pulling force. This maneuver occasionally can cause regurgitation. His gag reflex is reduced. His coughing force is very poor because of poor glottis control. He only clears his throat when he makes an attempt to cough. His voice is hoarse. These signs make one suspicious of bulbar involvement.

Psychological Evaluation

Dr. John Brantner*

The patient has an interesting psychological report. As far as could be determined from the Peabody Picture Vocabulary test, the patient has an intact personality and a relatively intact intelligence. His personality is pleasing and attractive. In the psychological testing situation he is persistent and patient and does not display temper or frustration. He is socially perceptive and responsive and less worried about his own feelings than he is concerned with the feelings of others. He displays a general thoughtfulness, politeness, and sweetness of temperament that continues in what must be very difficult situations. His vocabulary of understanding is large and does not appear to be impaired. He is in the top 10% of the general population in the number of words whose meaning he understands. The patient was given the Leiter International Performance Scale test.** His performance on a wide range test is lower; about 80% of the

*Associate professor, Clinical Psychology, University of Minnesota Hospitals.

**Designed for people who have marked physical disability.

Continued

general population of non-handicapped adults do better than he does. His performance is uneven (as might be expected). The Leiter International Performance Scale test calls for very fine visual discriminations; he had to use his spectacles and a hand magnifying glass to see these. He found the manipulation of small blocks difficult, but he persisted to solution in many cases. His number sense is very good, and he is superior in his manipulation of numerical concepts. Some other abstract intellectual operations proved difficult; he had trouble with classifications and with mosaic block designs. He appeared to "get the idea" in these cases but was unable to execute them. Fatigue may have operated here also. He was persistent and cooperative, but the testing took four to five hours.

Social Service Evaluation

Miss Annie Laurie Baker*

The patient was born in South Dakota. His father was a farmer. When he was about seven his parents were divorced and his mother remarried. The patient did not get along with his stepfather and went to be with his father in Nebraska when he was twelve years old. He stayed with him through his sophomore year in high school and then got a job working on a ranch taking care of horses.

When he was eighteen, he hitch-hiked and walked to Idaho to get a job in a lumber camp. This was during the depression. In 1930 he joined the marines and was stationed in the Orient, spending most of his tour of duty in Shanghai. He was discharged in November, 1935.

While he was visiting his brother who was a farmer in Nebraska, his brother had an accident and the patient remained to take care of the cattle. In the spring of 1936 he went to Fairmount, Minnesota, where his father had a job as a night watchman at the canning company, and obtained employment there in the refrigeration department. As he showed considerable promise, the company paid for correspondence courses in refrigeration engineering. Incidentally, he had completed high school by correspondence also.

When the company sold out to the Birds Eye company, he was transferred to the plant in Waseca. Subsequently, when he became confined to a wheelchair, he was transferred to the purchasing department. He has not been able to work for the past five years. He belongs to the Masonic Lodge, was active in church affairs, enjoyed sports and had many friends. His wife works as an office clerk from 5 P.M. to 1:30 A.M.

The family own their own home, a modern one-story six-room bungalow. Their income consists of the patient's total disability payments and his wife's earnings. The County Welfare Department has given State and University papers to pay that portion of the medical expenses not covered by insurance.

This is a family of competent resourceful people — able to handle adversity. The patient has been without a salary for several years; but together he and his wife have been able to raise and educate their three children, own their home, and continue free from debt.

The Management

Management of the Hemoptysis

Dr. Bergstrom

We still are left with the primary medical problem of not knowing the source of his hemoptysis. Does he have tuberculosis which is now activated? We do not really see any evidence for this, but we are planning to do planography in hopes of getting a little better picture of his apices. This man may possibly have chronic bronchitis without any finding on chest x-ray. In some of the recent literature the incidence of small amounts of hemoptysis with such a condition is quite high, but these patients almost always have a great deal of sputum production. Whether or not this man's sputum production is absent because of his neurological disease, we are seriously considering that he should have bronchoscopy because of the unilateral vocal cord disease, the episode of hemoptysis, and the history of heavy smoking. There is a remote possibility of an occult carcinoma of the lung which could be seen at the level of the carina.

Dr. Soll

Could this be done safely?

Dr. Bergstrom

Yes.

Dr. Richard Magraw*

What is his respiratory reserve?

Dr. Bergstrom

The vital capacity is 1.2/2.0. He virtually cannot count at all past four or five. I have seen patients with vital capacities less than one tolerate bronchoscopy very well. Bronchography is a different situation; it would be a relatively dangerous procedure.

Dr. Soll

Is there any evidence that the bleeding originated inside of the mouth? Doesn't he have very bad teeth?

Dr. Bergstrom

He has a very bad dental condition, but there is no evidence of gingival bleeding. The dentists are scheduled to see him.

Management of the Neurological Condition

Dr. Soll

There is no specific therapy known that will retard the progressive neurological involvement in this condition. Good nursing care, however, is extremely important in making the patient as comfortable as possible.

The carotid bruit which this patient has is undoubtedly significant but I am hesitant to recommend investigation by angiography now in view of his hypertension and the far advanced stage of his neurological condition.

Dr. Meelhuysen

In order to prevent limitation of shoulder movements, one can teach the patient not only to lie with his arms along his sides, but also to put his hands behind his neck while supine. This maneuver abducts and externally

---

*Director, Comprehensive Clinic Program, University of Minnesota Hospitals.

Continued

rotates the arm, enabling it to maintain its range in these directions. It is also good to know which muscles of the forearm are spastic, because of their tendency for structural shortening. His wrist flexors are tight. Keeping the wrist and metacarpal phalangeal joints flexed, a non-sustained clonus in the long finger flexors can be demonstrated by subjecting each finger individually to a sudden extension stretch.

Presently we are able to reduce spasticity in isolated and selected muscles by motor point blocking.* Partial blocking of the major shoulder adductors make abduction easier and could relieve discomfort on motion in this joint. It is my impression that spastic and tight shoulder adductors can pull the head of the humerus downwards, making it pivot in the wrong position in the glenoid fossa in the early phase of abduction. I have seen several cases in which the capsule has been unduly stretched, causing shoulder pain on motion; in these cases blocking the pectoral major and/or the teres major and latissimus dorsi muscles have alleviated the discomfort a great deal. Our patient does quite well on shoulder movements although he may have to limber up a bit. I would not suggest any motor point blocking of his long finger flexors at this time for the simple reason that his finger dexterity is still functional. Finger extension exercises should be done, nevertheless. If one decides to block the long finger flexors at a later date, blocking the flexor digitorum sublimis muscle, which inserts at the base of the middle phalanx of each finger, is preferable. I have noticed particularly in these patients that a spastic flexor digitorum profundus muscle enables them to use their fingers as a hook; however, if this deep long finger flexor muscle is blocked, the hand cannot be used even as a hook.

For the lower extremities I would suggest blocking of selected muscles followed by prolonged stretching of the contractures. This would help him in his transfer activities. In order to relieve the marked ankle clonus, it is important to determine whether the clonus is in the gastrocnemius, in the soleus or in both. His clonus is primarily located in the soleus; so there is no reason to block the gastrocnemius. When checking for ankle clonus, I do it in two ways: First, I extend the knee as much as possible and then try to elicit clonus by dorsiflexing the foot. In this position very little clonus is produced in this patient; however, if I then bend his knee, the clonus becomes more intense. In the latter position, the gastrocnemius becomes more relaxed and the soleus comes under more tension. This indicates to me that the clonus is primarily located in the soleus. With this finding, blocking of the soleus only should eliminate his ankle clonus. His standing posture will also improve, because the plantar flexion spasticity forces him to bear most of his weight on his forefoot, making him more unsteady on stance. Since the patient sits most of the day time, he should be instructed to lie prone to counteract the tendencies for developing flexion contractures in the hips as well as in the knees. One of our recommendations at the time of his discharge will be to alternate sitting and prone positions more adequately, if further deterioration of flexion contractures is to be avoided.

The degree of contractures he has at the present can be alleviated by reduction of his spasticity followed by prolonged stretch. The former permits stretching measures to be more effective. The reason for this is that any transfer activity becomes easier and consequently requires less energy when fewer contractures are present. Thus improving his standing posture is a goal within his reach.

---

*Motor point blocking — temporary interruption of motor innervation by injection of dilute phenol solution into muscle near point at which motor nerve enters muscle.

The gag reflex can be used as a functional exercise for the entire oropharynx; this should be done preferably before meals. The patient mentioned that he has no wheelchair with removable arm rests of the desk type. For a person in his situation transfer activities would be easier with this added feature. He could also move closer to the table. Another desirable accessory for his wheelchair are leg rests that allow leg elevation. Although his desire is to be able to walk again, I will not set this as an immediate goal, since he has not walked for at least six years.

Conclusions

1. Complete bronchoscopy in order to determine, if possible, the cause of the hemoptysis.
2. Insure good nursing care in the home to prevent further contractures and minimize the possibility of aspiration.
3. Undergo a progressive program of therapy as outlined above to make the patient more independent and possibly improve his standing posture.
4. Obtain a new wheelchair for the patient.

Addendum

A bronchoscopic examination was performed which revealed no satisfactory explanation for the patient's hemoptysis. After the recommended procedures were done to reduce the spasticity and contractures of the lower extremities, progressive training was begun to facilitate transfer activities and ambulation. By the time of discharge from the hospital, the patient was ambulating short distances with two broad-based canes.

Robert Soll, M.D.
University of Minnesota Hospitals

Participating in the conference were: Student Doctor Ross Olson; Dr. Robert Soll, Neurologist; Dr. John Bergstrom, Medical Fellow; Dr. Frank Meelhuysen, Assistant Professor, Physical Medicine and Rehabilitation; Dr. Richard Magraw, Director, Comprehensive Clinic Program; Miss Annie Laurie Baker, Director, Social Service Department and Dr. John Brantner, Associate Professor, Clinical Psychology.

Buckle Up

Never stop on a freeway except for an emergency

If you need to stop on a freeway, signal as early as possible. Drive promptly onto the shoulder of the road. If you need help tie a handkerchief to the radio antenna, raise the hood, or tie a handkerchief to the left door handle. At night use flares or reflector or leave the car lights on. Leave the car only from the right side, and do not stand on or close to the roadway. Don't hitchhike. Stay with your car until help arrives. Freeways are patrolled regularly.

Don't stop if you observe a disabled auto on the freeway. Instead, report it to the authorities at your first opportunity.

Better to sink beneath the shock
Than moulder piecemeal on the rock. — Byron

MOLECULAR REMODELING—

laboratory exercise or clinical necessity?

More than twenty-five years have passed since the discovery of the diuretic activity of sulfanilamide started pharmacologists on a succession of molecular remodelings to find the ideal diuretic.

Diuresis—a sought-after clinical effect from an unwanted side effect

It started in 1937 when a clinician reported that the administration of a sulfonamide was sometimes accompanied by an unexplainable side effect—metabolic acidosis.[1] Three years later the side effect was explained. The sulfonamide radical of sulfanilamide inhibited carbonic anhydrase,[2] the enzyme responsible for converting carbon dioxide and water to hydrogen ions and bicarbonate ions.

Later, other investigators showed by dog experiments that metabolic acidosis probably resulted when the inhibition of carbonic anhydrase upset the exchange of hydrogen and sodium ions, causing increased excretion of sodium as the bicarbonate.[3]

It was twelve long years after the first report of the unexplainable side effect (metabolic acidosis) that it was finally shown that large doses of sulfanilamide administered to edematous patients were indeed capable of promoting diuresis.[4] However, the possibility of toxic effects from its prolonged use and its relatively weak diuretic action made it impractical for clinical use as a diuretic.[5]

Because the inhibition of carbonic anhydrase seemed to be the key to effective diuresis, investigators began to look for more potent enzyme inhibitors —in the hopes that they would be more effective diuretics.

The most important of these early compounds, acetazolamide, enjoyed several years of fairly wide clinical use.

Its carbonic anhydrase inhibitory activity was several hundred times greater than that of sulfanilamide.[6] The increase in inhibitory activity, however, increased not only the excretion of sodium and bicarbonate ions, but also the excretion of potassium.[7] And, like its predecessor, acetazolamide precipitated mild acidosis. Its prolonged use could result in hypokalemic acidosis.[7]

The 'thiazides'—an answer to the metabolic acidosis caused by carbonic anhydrase inhibition

Despite the fact that the sulfonamide group appeared to be responsible for carbonic anhydrase inhibition which in turn appeared to be responsible for diuresis, investigators began to synthesize compounds with structural alterations to the sulfonamide group.

The first major breakthrough came with the synthesis of chlorothiazide. Altering the sulfonamide group did indeed alter the ability of chlorothiazide to inhibit carbonic anhydrase—it was only 1/10th as potent as acetazolamide in inhibiting the enzyme.[8] Despite the drop in inhibitory potency, however, chlorothiazide proved to be an effective diuretic—an observation that led to the conclusion that its diuretic action was due to some mechanism other than its action on carbonic anhydrase.[9, 10]

For effective diuresis, chlorothiazide was administered in daily dosages ranging from 250 to 2000 mg.[11] It increased the excretion of sodium and chloride; and, to a lesser extent, potassium and bicarbonate.[11] The excretion of potassium appeared to be maximal at higher dose levels at which, theoretically, the carbonic anhydrase inhibitory effect is more active.[11] Its prolonged use, therefore, could sometimes result in metabolic hypokalemic, hypochloremic alkalosis.[7]

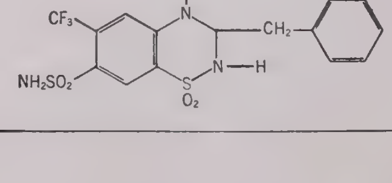
Naturetin—effective diuresis with more favorable electrolyte balance

Other thiazides followed—with improvements being aimed at two particular areas: 1. attempts to increase diuretic action in relation to the milligram potency of the drug, and 2. attempts at a more favorable sodium/potassium ratio in the urine, i.e., to decrease the excretion of potassium while maintaining the excretion of sodium.[12]

One of these, Naturetin, Squibb Bendroflumethiazide, has made advances on both these points. "By adding a 3-benzyl radical to hydroflumethiazide a rather dramatic reduction in dose range is accomplished. With this drug, effective sodium excretion is obtained with doses between 2.5 and 10 mg., which is a 200 to 1 ratio as compared to chlorothiazide..."[13]

Moreover, due probably to its virtual lack of carbonic anhydrase inhibition, Naturetin (bendroflumethiazide) has been shown to cause less potassium and bicarbonate loss and less alteration in urinary pH than either chlorothiazide or hydrochlorothiazide.

Naturetin is outstandingly effective not only in establishing, but also in maintaining, excretion of retained fluid in edematous patients. And its duration of action is sufficiently prolonged to allow a single daily administration in most patients. Naturetin is also an effective antihypertensive agent.



Contraindications: Severe renal impairment; previous hypersensitivity.

Warning: Ulcerative small bowel lesions have occurred with potassium-containing thiazide preparations or with enteric-coated potassium salts supplementally. Stop medication if abdominal pain, distension, nausea, vomiting, or G.I. bleeding occur.

Precautions: The dosage of ganglionic blocking agents, veratrum, or hydralazine when used concomitantly must be reduced by at least 50% to avoid orthostatic hypotension. Electrolyte disturbances are possible in cirrhotic or digitalized patients.

Side Effects: Bendroflumethiazide may cause increases in serum uric acid, unmask diabetes, increase glycemia and glycosuria in diabetic patients and may cause hypochloremic alkalosis, hypokalemia; cramps, pruritus, paresthesias, and rashes may occur.

Supplied: Naturetin (Squibb Bendroflumethiazide) 5 mg. and 2.5 mg. tablets. Also available Naturetin c̄ K [Squibb Bendroflumethiazide (5 or 2.5 mg.) with Potassium Chloride (500 mg.)]. For full information, see Product Brief.

Medical Seminar

Frigidity in Women

A Symptom Not A Diagnosis

Presented as a Seminar
Sponsored by
The Faculty of the Mayo Graduate School of Medicine

PHYSICIANS ARE sometimes confronted with problems in the female patient that are not wholly attributable to an organic cause. In fact, many difficulties may be entirely psychologic and merely be manifested by organic complaints that the patient voices to her doctor. Such a conscious or unconscious attempt to avoid a discussion of the specific difficulty that she feels is paramount must show how deeply the problem troubles the patient. The physician must be astute enough to discern this type of problem and give it the attention it deserves.

Frigidity is a symptom of an underlying difficulty that may come to the attention of the physician in a number of ways. Some patients speak of it as an initial complaint. Others present various, vague organic or emotional problems as outward manifestations of this symptom. Generally, only after the doctor himself suggests this problem will the patient begin to discuss it. Many patients are reticent probably because they are ashamed or reluctant to discuss matters closely associated with sexual relations. However, the physician who is willing to spend the time and effort discussing these matters will find that many patients readily reveal their fears and anxiety about frigidity. Keeping foremost in his mind that frigidity is a symptom and not a diagnosis, the physician may then be able to make an accurate determination of the underlying cause and to suggest successful therapy.

The purpose of this paper is to discuss the definition of frigidity and its incidence, to outline a classification of the various types of frigidity, and to discuss the diagnosis, causes, and treatment of this entity. Although the specific cause of frigidity remains controversial, an understanding of the possible causes should reveal the methods of diagnosis. Even though a significant percentage of patients must be treated by psychiatrists, there are some patients with the symptom of frigidity to whom the practicing physician can offer successful diagnosis and therapy.

Incidence and Possible Mechanism

The incidence of frigidity in women has been listed by various authors[1-4] as ranging from 33 to 80%. Such a widespread discrepancy undoubtedly arises because there is no generalized agreement regarding the exact definition of frigidity in women. In animals the sexual urge is relatively easy to define because most of them exhibit the typical reaction known as "heat" or "estrus." This phenomenon is generally believed to be activated by the hormones circulating in the blood, and the willingness or unwillingness to mate in animals is controlled by these hormones. In the human, however, it seems that the sexual urge is completely independent of circulating hormones and is controlled by centers in the cerebral cortex. Mann[5] has pointed out that progesterone or estrogen, given singly or together, does not appear to change the libido of the female. Also, women who have undergone total hysterectomy and bilateral salpingo-oophorectomy or radiation of the pelvis show no predictable alteration in sex drive despite the fact that the ovaries are no longer able to produce the gonadal hormones. He suggested that the sex urge in

Continued

humans has become independent of hormonal concentrations through the process of phylogenic development. No matter what the cause, there is no question that the sex drive in humans is much more difficult to assess than that in animals. This conclusion has a most important role in attempts to determine the incidence of frigidity.

Definitions of Frigidity

The frame of reference usually used in the definition of frigidity is the presence or absence of orgasm. Since orgasm in the female cannot be objectively measured as it can with ejaculation in the male, there is some difficulty in using this as a criterion. Two distinct types of orgasm have been postulated: clitoral and vaginal. The chief sensory region for erogenous sensation in the female is the clitoris, and it is the source of clitoral orgasm. It is supplied with a large number of genital corpuscles that are stimulated by various types of sexual activity. The female has an orgiastic center in the sacral cord that mediates the stimulation from the genitals as the impulses pass to the cortex for reception and cortical facilitation of the response. Marmor[6] discussed the presence of kinesthetic receptors within the vaginal wall that are stimulated by the erect penis and are also connected to these sacral and cerebral centers. These nerve endings are responsible for the stimulation of vaginal orgasm. Kinsey and associates,[7] however, believed that the sensory nerve supply to the vaginal lining is so meager that vaginal orgasm does not exist. Vaginal secretions during sexual activity are also believed to be objective evidence of sexual arousal.

Freud[8,9] believed that the woman's ultimate sexual response is determined by childhood experiences. He stated that several factors combine to produce the final sexual adjustment. In her earliest years a young girl is most closely attached to her mother through her dependence on the mother for feeding, warmth, and clothing. The mother also becomes the initial disciplinarian. The young girl has two sexual zones: the clitoris and the vagina. Since the clitoris is more readily accessible for attention, it is the center of childhood sexual interest. Any stimulatory activity that the child employs involving the clitoris usually brings a rapid rebuke from the mother. Repeated clitoral manipulation, which the young girl may find pleasurable, produces only more emphatic and stringent admonitions from the mother. The possible end result may be a deep resentment against the mother by the child for denying her a pleasurable activity, or it may be a deepseated inhibition for any activity associated with the genitals. As the young girl grows older, Freud believed that her attention normally turns to a closer attachment to the parent of the opposite sex, the father. She may become aware that she does not have a penis, and this may produce resentment against the male sex. All these factors combine to influence the young girl's final attitude toward sex. Freud believed that three things may happen: The young girl may acquire an aversion to sexuality, which will result in her eventual frigidity as an adult; she may refuse to accept the opposite sex, which can result in homosexuality; or she may undergo a normal transition and acquire definite interest in the opposite sex while accepting her own sex. (This form of development results in "normal" sexual adjustment.) Freud further believed that as the young girl goes through puberty her sexual interest is transferred from the clitoris to the vagina and that the sexual pleasure of clitoral orgasm in childhood is replaced by the vaginal orgasm of the "normal" adult female. It was his contention that an adult woman who does not experience vaginal orgasm is frigid.

Hitschmann and Bergler[10] also believed that the absence of vaginal orgasm is the sole criterion for determining frigidity. Although the differentiation between clitoral and vaginal orgasm may seem like splitting hairs, they believed that the clinical facts prove otherwise. They stated that the neurotic woman cannot achieve vaginal orgasm, whereas the well-adjusted woman can. They contended that clitoral orgasm is achieved only by masturbation, whereas vaginal orgasm is achieved by intercourse. Thus clitoral orgasm is an infantile act, and vaginal orgasm is an adult one.

Other authors[11-13] are not so narrow in their definition of frigidity. Most describe frigidity in terms of either the absolute or relative absence of pleasurable response to erotic stimuli. Orgasm is often used as one means of determining a pleasurable response; but, as McGuire and Steinhilber[12] pointed out, many women may gain pleasure from sexual intercourse although they do not experience an orgasm. Thus, if orgasm or the absence of it is used as the basic criterion for defining frigidity, the incidence will be much higher than a definition based on the presence of pleasurable response to erotic stimuli. Since the presence of vaginal orgasm is doubted by some and the presence of orgasm—whether vaginal or clitoral—is often hard to determine, it would seem more reasonable to define frigidity as the total or relative absence of pleasurable response to erotic stimuli.

Classification of Frigidity

There have been many suggestions for classification of frigidity. One such classification divides the various aspects into organic frigidity, true frigidity, and pseudofrigidity.

The causes for organic frigidity are easily understood. Painful intercourse due to a tight hymeneal ring, atrophic vaginitis, or other organic pathologic changes that produce dyspareunia prevent the woman from gaining pleasure from the sex act. Exhaustion due to overwork or systemic illness can make the woman reluctant to undertake relations. Impotence, premature ejaculation, or poor technique by the male partner can decrease or eliminate the pleasurable response by the female.

Rutherford and associates[13] define true frigidity as the complete and absolute absence of pleasurable response to erotic stimuli of any kind. Likewise, they define pseudofrigidity as frigidity in the individual who is capable of sexual arousal, with or without orgasm. Both classes are merely points along a spectrum of pleasurable sexual response. Thus the largest group of patients would probably be classified as pseudofrigid since they can be aroused but experience an unfilled sexual response. The evident manifestations of the pseudofrigid patient may be tension, guilt, anxiety, or multiple ill-defined physical complaints often associated with the pelvis. Weiss and English[4] more specifically list the sexual responses of the truly frigid or pseudofrigid patient as follows: (1) occasional failure to achieve orgasm; (2) only occasional orgasm; (3) mild pleasure in coitus without orgasm; (4) vaginal anesthesia, with no special aversion to coitus; (5) vaginal anesthesia with special aversion to coitus; and (6) dyspareunia and vaginismus. These responses reveal the variety of reactions that are possible in a frigid woman.

Causes of Frigidity

As was stated previously, frigidity is merely a symptom of an underlying difficulty, and so to determine the cause of the frigidity, the cause of the underlying defect must be discovered. Weiss and English[4] have provided an outline of the various psychologic causes of frigidity in the female. An understanding of these causes provides insight into the problems.

Frigidity may be caused by fear of disapproval or punishment. Many children are impressed from their very earliest years that everything associated with sex and the genitals is taboo. Parents often praise young children for demonstrating an interest in their nose, ears, hands, feet, and so forth, but sharply criticize and often discipline them when they touch their genitals. As children grow older and begin to associate with members of the opposite sex, girls are often taught that men are beasts who desire only sexual gratification. In our society, because premarital sex experience by the woman is definitely frowned upon, it is often difficult for a woman to adjust her standards to the married state. In the space of a few short minutes of a wedding ceremony, sexual activities that have been forbidden to her for years become legal and sanctioned—albeit expected. It is not difficult to understand how some women ingrained with sexual taboos all their lives fail to adjust "overnight." Young married couples who are forced to live under the same roof with parents may

Continued

experience difficulties. The girl may fear psychologic disapproval or even bodily injury from a parent who has been adamant against her sexual activity during her single years. Her inhibitions prevent her from deriving a pleasurable response.

A young woman may have heard her mother talking about how terrible pregnancy was. Her mother may have impressed upon her the physical discomforts and pain of bearing a child. In addition, she may have impressed upon her daughter that with motherhood came the loss of whatever freedom she may have enjoyed and the addition of tedious responsibilities associated with the raising of children. It is no wonder that she gets little or no pleasure from sexual relations which could produce pregnancy.

A woman may be frigid as a conscious or unconscious manifestation of hostility toward her marital partner. Women who have often gone through an unpleasant childhood as a result of a mean or unkind father or brother find it hard to accept any man in a close relationship. Some women may unconsciously resent the domination of their lives by men. This may be a generalized resentment against the dominant positions given to all men in our society, or it may be a personalized resentment against the dominant position of a husband over a wife. Such women are frigid because they refuse to allow men to dominate them in the one area which they know is so important. The wife who feels her husband falls short of her expectations or who is maintaining an extramarital relationship may be frigid with her husband.

The female may have an underlying fear of injury to her genital organs. She may have heard how painful intercourse can be and have heard that the penis is often too large for the vagina. Such fear of pain or injury can cause her to lose all desire for an association that might bring such a result. Women may also have a fear that their participation in intercourse can cause harm to the male genitalia.

Another common unconscious cause of frigidity is conflicting loves. A woman who has had a very close attachment to her father, a brother, or an uncle may find it impossible to develop a close sexual relationship to another man. Since her ties to the father or brother have not had a sexual component, she finds it impossible to include this area in her new close relationship with a man.

One group of women never develop the emotional capacity to be able to have an intimate relationship with a person of the opposite sex. They are never able to shed the close attachment they have had to their mother—a member of the same sex—and so develop a state of latent homosexuality. These women do not find relationships with members of the opposite sex meaningful and so refuse or are reluctant to participate in such relationships.

Finally, frigidity may be caused by a feeling of self love so great that there is no room for emotional attachment to another. This condition is often seen in people who are severely neurotic or psychotic. Some women become so engrossed in their own activities, their dress, and their makeup that they do not have time to think of another person. Another manifestation of excessive self love is seen in women who devote their lives totally to their children. They see their children as a continuation of themselves and become so engrossed in their care that they have no thoughts for their own emotional relationship with their husband.

Diagnosis of Frigidity

The detection of women with underlying causes of frigidity may not be easy. The truly frigid woman who has never experienced orgasm or pleasurable sexual response will rarely come to the physician on her own. She does not know that something is lacking in her response because she has never experienced it. The husband will often bring this type of patient to the doctor. Moreover, women who do not experience orgasm, but who do derive some pleasure from sexual activity will not usually discuss the lack of orgasm as an initial complaint. Usually, it is the woman whose lack of adequate sexual response is producing marital discord who comes to the physician with complaints that relate to sexual activities.

A careful history is the cornerstone of diagnosis. Vague complaints related to the pelvis are often tip-offs to sexual difficulty. Often the patient will fail to mention sexual relations altogether. Then the doctor must inquire and attempt to determine the patient's sexual adjustment. If the patient begins to discuss the lack of pleasure associated with sex, then the physician can begin to see if he can fit the underlying cause into the scheme of etiology that has been outlined.

A complete physical examination is always necessary. Such an examination should enable the physician to pick up various causes of dyspareunia. The causes of frigidity associated with systemic disease or other organic pathologic changes should be evident. Likewise, problems associated with physical exhaustion and overwork are easily recognized.

Frigidity caused by fear of criticism or ridicule, by fear of pregnancy, or by an excessive parental conditioning on the taboos of sex may be evident after a short discussion with the patient. The other causes such as hostility toward the partner or conflicting loves usually need several sessions with a psychiatrist to become evident.

Treatment of Frigidity

Kroger[14] suggested that there are four means by which the underlying causes of frigidity may be treated.

Medical Therapy

The first can be termed medical therapy and can be carried out by any physician who makes the diagnosis of a medical cause of frigidity. A hymen can be ruptured or stretched, and vaginal atrophy or vaginitis can be treated. Kupperman[15] and Burdine and associates[1] have suggested androgen therapy in women who have difficulty experiencing orgasm. They have stated that androgen increases libido and increases the frequency of orgasm. Burdine used a long-acting parenteral androgen (Delatestryl) in doses of 200 mg. every two weeks. He emphasizes that this type of hormonal treatment is most effective when used in conjunction with psychotherapy. He stated the belief that hormonal treatments speed the results of the psychotherapy.

Superficial Psychotherapy

Kroger's second area of therapy is termed "superficial psychotherapy." Those women who have a fear of pregnancy can be helped with an explanation of the course of pregnancy, labor, and delivery. The joys of childbearing and motherhood can be emphasized. A series of discussions gives the patient time to readjust her thinking and become emotionally acceptable to pregnancy and motherhood. During this period of readjustment, adequate birth control measures can be prescribed. Clumsy or inept technique on the part of the male partner can be remedied by discussions with the husband. If a young married couple is living with parents and this proximity seems to be the cause of the wife's symptoms, the physician can call this to their attention and encourage a move. Thus the various areas of mild emotional disturbances that produce symptoms of frigidity are amenable to treatment by the practicing physician.

Psychiatric Therapy

The more deep-seated causes for frigidity must be reserved for treatment by the psychiatrist. The physician who realizes these deep emotional conflicts must convince the patient that psychotherapy is the treatment of choice. The methods of treatment range from hypnotherapy and electric shock to psychoanalysis. Although these methods are not in the realm of this discussion, it must be remembered that these treatments, of necessity, will take time because the causes are deepseated.

Prophylactic Therapy

Finally, the most successful form of therapy is prophylactic: prevent the condition before it occurs. From the very earliest ages, the parents must attempt to assume reasonable attitudes toward sex with their children. They should attempt to show that sex in its various aspects is a normal function of the human organism. The subject should not be overemphasized or strictly forbidden for dis-

Continued

cussion but rather approached in a logical manner, similar to other areas of childhood instruction.

Kroger[14] has suggested that the following recommendations be given to parents:

1. A child's home environment should be based on love, affection, tolerance, and discipline.
2. The parents should not let the child know they were disappointed with the sex of the child.
3. The difficulties of pregnancy, labor, and delivery should never be related to the child.
4. The parents should assume reasonable attitudes toward bathing, toilet training, and childhood masturbation.
5. The father should not be seen nude by the daughter and the daughter should not observe her father in excretory activities.
6. Children should sleep in a bed alone and should not observe or overhear the parents during sexual relations.
7. The parents should give straightforward explanations of menstruation and sex at the time of puberty.
8. Parents should not overemphasize chastity to the daughter.

Virtually any physician, no matter what his field of specialization, can practice good therapy by answering a patient's questions or referring her to someone who can. The pediatrician can discuss the importance of proper sex attitudes and upbringing with parents. Premarital examinations by physicians should be encouraged. At that time, any possible organic cause of frigidity can be diagnosed and treatment instituted. A discussion of female anatomy and techniques of intercourse can alleviate much fear and concern in the young woman. Any questions that the girl may have about sexual relations can be discussed frankly.

Conclusions

Frigidity is a symptom of an underlying disorder that can be prevented by a reasonable attitude toward sexual matters by parents. Premarital examination can reveal any organic or mild emotional difficulties that could cause a lack of sexual response in a woman. Deepseated emotional problems such as hostility toward the marital partner or conflicting loves must be diagnosed by the psychiatrist who can then carry out the appropriate treatment.

Differential Diagnosis of a Case of Violent Behavior and Papilledema[*]

An Example of Increased Intracranial Pressure Without Early Localization

"A Case of Violent Behavior and Papilledema"

History

A forty-three-year-old farmer was admitted to the hospital after threatening his wife with a butcher knife.

The patient, who was a good historian, complained to the psychiatrist of throbbing headache, a loss of balance over four to five months, and a tendency to fall to the right. His eye grounds were examined, and he was sent to the Neurology Service.

Additional history obtained included: multiple childhood ear infections; hemorrhage from the right ear while flying in 1942 and diminished hearing in the ear since; the fact that his headache was worse in the morning and sometimes accompanied by nausea. He denied vomiting, vertigo, seizures, blackout spells, weakness, lethargy, or change in his mental ability.

He stated that he was hypersensitive but denied other illness, operations and allergies. He had one cerebral-palsied child but no other suggestive family history. No family member shared his affliction. He had not smoked in three months and denied excessive alcoholic intake.

Physical Examination

The temperature was 98.8 F, the pulse 80, the respirations 18 and the blood pressure 130/80. Examination revealed a left-handed forty-three-year-old man who appeared his stated age.

Positive physical findings were limited to the neurologic examination except for a perforated drum on the right with visible ossicles. His mental status was normal except for a tendency to project his troubles onto his wife. His station was normal with a negative Romberg. He tended to walk to the right with his eyes closed, and fall to the right with tandem walking. Finger-to-nose, heel-to-shin, and rapid alternating movements were performed well. There was no sensory deficit or motor weakness, and his reflexes were equal and active with downgoing toes. He was anosmic.[**] There was bilateral papilledema, but his fields were full and his pupils were equal and reacted well. He had nystagmus on lateral gaze, particularly to the left, and his extraocular movements were intact. Hearing was diminished on the right, with bone conduction greater than air.

Laboratory Findings

The hematocrit was 49 vol.%, the white cell count was 10,300 with 65% neutrophils, 24% lymphocytes, 10% monocytes and 1% eosinophils. The urinalysis was unremarkable, the serology negative, the fasting glucose 90 mg.% and the urea nitrogen 19 mg.%.

[*] This presentation is based on a Neurology-Neurosurgery Clinicopathological Conference held at the State University of New York Upstate Medical Center on May 13, 1966.

[**] See Test Your Word Score Page 1855.

Continued

The chest x-ray was unremarkable, a skull series revealed a large sella turcica, and tomograms were made of that area. A mercury brain scan was negative. A closed lumbar puncture revealed an opening pressure of 350 mm. and a closing pressure of 250 mm. after 5 cc. of cerebrospinal fluid were removed. There were no cells, the fluid was clear and colorless, the total protein was 250 mg.% and the colloidal gold 55544332211.

Hospital Course

On the 19th hospital day, the patient was noted to have weakness in his right arm and a diminution of graphesthesia.* He was seen by a neurosurgical consultant, who obtained the following additional history: For 10 years he had had bifrontal headaches and some nausea, and although he rarely vomited, this always relieved the headache. For five years he had noted a pulsatile noise in both ears. For three to four years he had been forced to urinate each time he put his hands in water. He had been unable to smell for one year and had noted blurred vision bilaterally accompanying his headaches for one year.

On the 25th hospital day bilateral parieto-occipital burr holes and a right brachial angiogram were performed. The ventricles were noted to be enlarged. On the 27th day a ventriculogram and a pneumoencephalogram were performed. The ventricular fluid had a protein of 3 mg.%.

The following day the patient became acutely apneic. Mouth-to-mouth respiration, endotracheal tube, respirator and ventriculostomy, and eventually tracheostomy were all required to revive him. The ventricular pressure remained high, and on the 32nd day a Spitz valve was inserted, following which he became very alert, although unable to take oral feedings.

From the 33rd to the 40th day the patient gradually deteriorated with development of fever, polyuria, hypernatremia (Na 170 meq/liter) and azotemia (BUN 146 mg.%). These conditions were largely corrected by cessation of hypertonic tube feedings and rehydration, but the valve appeared to be functioning poorly. The ventricular pressure on the 40th day was 300 mm. and the valve was replaced. The protein in the ventricular fluid was 78 mg.%.

On the 70th hospital day a peri-urethral abscess forced withdrawal of the Foley catheter, and after an initial drop in temperature, he became febrile at 103° F, then became shocky and died while being treated with antibiotics, steroids and vasopressors on the 72nd hospital day.

An autopsy was performed.

Roentgen Interpretation

Dr. Alfred S. Berne:**

Plain films of the skull (Figure 1) reveal that the superior portion of the right petrous pyramid is ill-defined, especially in the region of the internal auditory canal. The detail is not optimal and a prominent condyloid foramen in the occipital bone partially overlies the internal auditory canal. However, there is suspicion of erosion of the right internal auditory canal.

A right brachial angiogram was performed (Figures 2-a and 2-b) and these films demonstrate evidence of dilated lateral ventricles. The anterior cerebral arteries are bowed and the thalamostriate vein on the right is convex laterally, indicating moderate to marked lateral ventricular enlargement. A specific diagnosis as to the etiology of the dilatation of the ventricles cannot be made from the angiogram.

A ventriculogram was performed (Figure 3) and demonstrates moderate to marked symmetrical dilatation of the lateral ventricle. The aqueduct of Sylvius is slightly dilated and is displaced to the left. The fourth ventricle is rotated and displaced to the left.

These films demonstrate an obstructive hydrocephalus due to a mass lesion on the right side in the posterior fossa. There is suggestion of

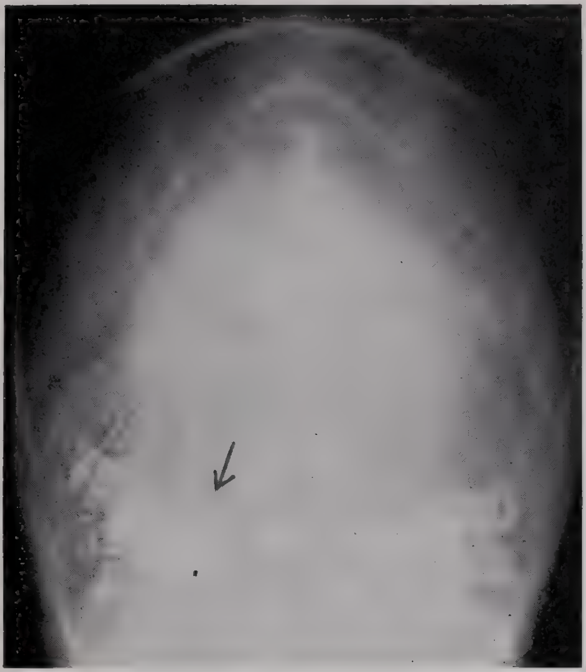

Fig. 1 — Towne view of the skull. The right internal auditory canal appears ill-defined and the porus appears enlarged.

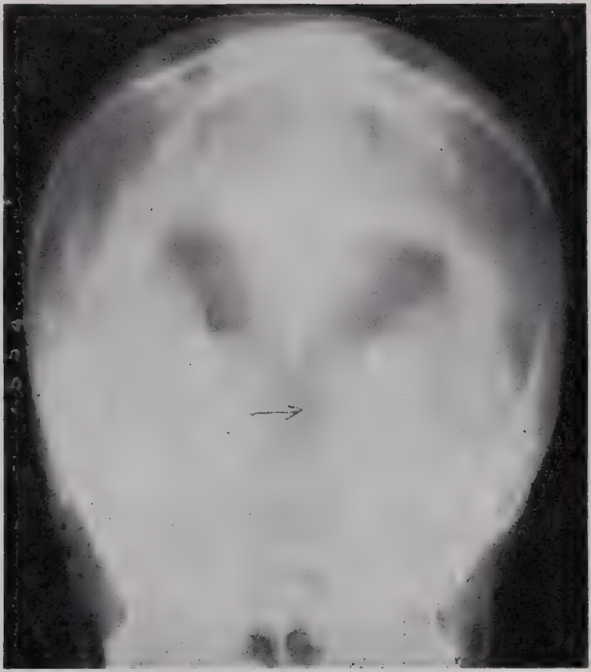

Fig. 3 — A reverse Towne view made during ventriculography demonstrating symmetrical marked hydrocephalus. The displacement of the aqueduct of Sylvius and fourth ventricle from the right to the left is seen.

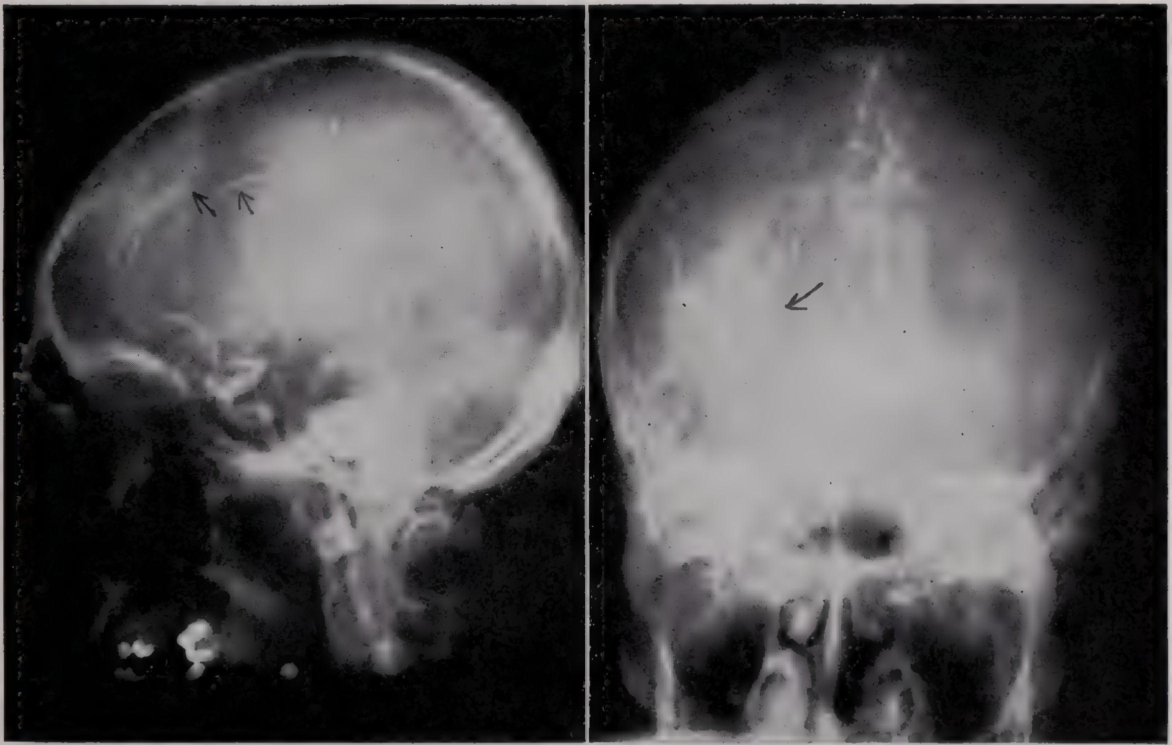

Fig. 2-a (left) and 2-b (right) — Lateral brachial angiogram and frontal brachial angiogram, arterial and venous phase respectively. The angiographic manifestations of dilatation of the lateral ventricles are seen. The thalamostriate vein is bowed laterally and there is bowing of the anterior cerebral arteries in the lateral view.

Continued

rotation of the fourth ventricle, and the change in the vicinity of the internal auditory canal together with this suggests that an extra-axial lesion in the posterior fossa on the right is causing the hydrocephalus. The diagnosis would be more definitive if the visualization of the internal auditory canal on the right side was of better quality or perhaps tomographic.

The other possibility would be an intra-axial mass on the right side; but in the lateral view there is no real kink at the junction of the third ventricle and the aqueduct.

Overview

Dr. Arthur Ecker:*

Without early localizing neurologic symptoms, this 43-year-old man presented with longstanding, progressive, increased intracranial pressure, ending in apnea, coma and death. This is an important practical problem, because the patient may have had a curable lesion.

For ten years the patient had had bifrontal headache with nausea, worse in the morning, and relief after vomiting. Early morning headache is often a clue to increased intracranial pressure. For five years the patient had heard a pulsatile noise in both ears. It is not stated whether others heard this or not. This is suggestive of an arterial bruit. If it cannot be heard by auscultation of the neck or head, sometimes its relationship to the pulse can be determined by the patient's beating with his hand in time with what he hears while the physician takes his pulse. For one year the patient had had blurred vision with headaches. This suggests failing compensation of increased intracranial pressure. The only symptom of papilledema is transitory blurring of vision. For four or five months there had been loss of balance.

Examination revealed bilateral papilledema. There is no mention of hemorrhage or exudates and presumably this papilledema is of the chronic type. A large sella turcica is reported. This suggests a slow process with reossification such as might occur with an intrasellar lesion, suprasellar lesion — such as craniopharyngioma,** or the dilated third ventricle of obstructive hydrocephalus. Less commonly an arterial aneurysm of an internal carotid artery or, rarely, one of the terminal portion of the basilar artery may produce enlargement of the sella. The lumbar puncture pressure was recorded at 350 mm. of water and the total protein content of the lumbar fluid was 250 mg. %.

On the day after the ventriculogram and pneumoencephalogram, there developed acute apnea and coma, a not uncommon complication of ventricular obstruction, usually ascribable to shifts in intracranial tissues. These include transtentorial movements of the brain stem up or down at the tentorial notch, buckling of the brain stem and secondary obstruction of cerebrospinal fluid pathways at the tentorial notch from herniation of temporal lobe or cerebellar tissue. There may be traction on the branches of the basilar artery. The result of these processes leads to hemorrhages in the brain stem and death. For these reasons the edges of the tentorium at the notch, in cases of increased intracranial pressure, can be called "the jaws of death." Furthermore, there may have been herniation of the cerebellar tonsils into the foramen magnum. In short, this is a case of progressive, increased intracranial pressure without early localizing neurological symptoms.

Special Features of This Case

Protein Content of Cerebrospinal Fluid

The total protein content of the lumbar fluid was 250 mgm.% at first and later 480 mgm.%. (On the contrary, the ventricular fluid at first contained 3 mgm.% of total protein, but after the valve was inserted, 78 mgm.%). This high protein content is a most valuable sign, suggesting that the lesion is in contact with fluid continuous with the lumbar fluid. It could be anywhere in the cranial or spinal subarachnoid spaces. However, it apparently was blocked — at least from the lateral ventricle sampled, where the protein content of the fluid was normal at first.

The mechanism of increased protein content of the lumbar fluid is unknown, but it has been suggested that tumors of the cerebellopontine angle act like spinal cord tumors, blocking the subarachnoid pathways. The protein content may be related to the vascularity of the tumor with back-pressure in the veins, to brain edema, to the rate of growth, to the shifting of the medullary axis or to breakdown of degenerative products of the tumor itself.

In the Journal, BRAIN, in 1952, Stern reported two of five posterior fossa meningiomas to have a total protein content of over 200 mgm. %. However, with meningiomas in general, in only 12% is the total protein over 200 mgm.%. Geoffrey Jefferson described three cases of cerebellar hemangiomas, in each of which the cerebrospinal protein content was over 500 mgm.%. Nevertheless, by and large, a high protein content in a case of increased intracranial pressure suggests primarily an acoustic nerve tumor. In a published series of these the protein content was over 50 mgm.% in 97% of the cases and over 200 mgm.% in 45% of the cases.

Cerebrospinal Fluid Pressure

The original pressure of the lumbar fluid was 350 mm. of water. After 5 cc. were removed the final pressure was 250 mm. The Ayala index* (final pressure divided by original pressure times amount removed) was 3.6. This is a low reading, well below the normal of 5.5. It suggests a diminished reservoir of cerebrospinal fluid, connected with the lumbar space. Therefore, this is *not* a case of communicating hydrocephalus with dilated ventricles. This conclusion is confirmed by the discrepancy between the protein content of the spinal fluid and that of the ventricular fluid. We therefore must seek an intracranial mass — such as a neoplasm, abscess or aneurysm — rather than simply blockage of the subarachnoid pathways.

Forced Urination

The patient was forced to urinate each time his hands were placed in water. Could this be a form of reflex epilepsy? No associated loss of awareness is mentioned. I was unable to find a case of forced urination as a sign of focal epilepsy in the literature. Nevertheless, the paper of Andrew, Nathan and Spanos, in the Journal of Neurosurgery for 1966,

Continued

---

*See Test Your Word Score Page 1855.

describing disturbances of micturition from lesions in the superior frontal convolution or the septal region (gray matter abutting the lamina terminalis and anterior commissure) suggests that such cases may some day be described. Penfield and Kristiansen described urinary incontinence in a number of cases of focal epilepsy, but this always occurred late in an attack or immediately after it. There was one patient with an urge to void who had microgyria* in the left frontal region. There was a single patient who had involuntary voiding as part of a minor seizure but none where it was precipitated by placing the hands in water.

The Bruit

A bruit of itself means nothing. However, it does occur in time with the heartbeat in cases of increased intracranial pressure in children. It is also present in arteriovenous fistulae. Occasionally it appears with a very vascular tumor — such as meningioma, glioma or tumor of the glomus jugulare and, uncommonly, with an arterial aneurysm. In describing nine cases of arteriovenous malformations in the posterior fossa, Olivecroner did not mention the presence of the bruit.

Localization in Cerebral Hemispheres?

There are a few clues that might suggest a supratentorial mass.

Psychiatric Aspects

Just before admission to the hospital the patient projected his troubles on to his wife and threatened her with a butcher knife. Does this point to a lesion in the frontal lobe? The presence of a psychiatric disorder can be ascribed to organic disease of the brain, but the nature and content of the psychiatric disorder depend not on the parts of the brain affected but on the background and nature of the patient. This was a late symptom in this patient who was mentally alert and a good historian. The alertness and good memory speak against a rapidly growing glioma or metastasis in the cerebral white matter.

Mercury Brain Scan

A mercury brain scan was reported negative. Such a scan is said to be positive in 85% of the large hemispheral tumors but misses most of the astrocytomas. It does recognize a small number of cerebellar tumors but misses most of the small deep tumors of the brain stem. Even if read promptly, a small arteriovenous malformation may be missed.

Anosmia

Bilateral anosmia was present for one year. Could this be an olfactory groove meningioma extending up into the frontal lobes? In 15 of Cushing's 29 cases of olfactory groove meningioma, anosmia was absent. However, choking of the optic disks with normal vision is rare in such cases, since optic atrophy occurs early. No local x-ray changes were described.

A suprasellar meningioma extending forward to the olfactory nerves is possible, but again, in these cases, blindness and optic atrophy come first and there is rarely papilledema. A primary tumor of the falx with direct pressure blocking the third ventricle or foramen of Monro can produce bilateral anosmia.

---

*See Test Your Word Score Page 1855.

We can conclude that in this case bilateral anosmia is likely to be a late sign of increased intracranial pressure and not of localizing value. For example, in Cushing's series of acoustic nerve tumors, anosmia was present in 17% of the cases. However, in the recent series of cases of acoustic nerve tumor, anosmia has been described in only 2 to 5% of the cases.

Lesions of the Third Ventricle

There was no postural effect on the headache, as in colloid cyst and other lesions of the third ventricle. There was no local visual or endocrine signs, no polyuria, polydypsia, or evidence of pituitary insufficiency.

Frontal Lobe

In frontal lobe tumors there may be incoordination and ataxia as well as increased intracranial pressure. However, a tumor arising in the frontal lobes or corpus callosum is likely to cause mental changes early. The absence of convulsive seizures and localizing defects point away from the sensorimotor cortex.

Posterior Fossa

As Jefferson has pointed out, there is an old neurological dilemma: in a patient with clear evidence of tumor is the lesion above or below the tentorium? There is often difficulty in discriminating between ataxia of cerebral or cerebellar origin. The issue will frequently be solved by special examinations. Even so, the preoperative diagnosis will often be one of probability rather than certainty.

Electroencephalography in Posterior Fossa Lesions

In the presence of papilledema a normal electroencephalogram is in favor of a posterior fossa tumor. This applies to most acoustic nerve tumors and metastases in the posterior fossa. Occasionally, in a large tumor of the posterior fossa, with distortion or involvement of the brain stem, there are bilateral slow waves — usually fairly rhythmic and regular — but never sharp waves, spikes or abnormal complexes (Pampiglione, 1953).

Ataxia

For four or five months the patient had loss of balance with a tendency to fall to the right. This was confirmed on examination when he walked to the right on tandem walking or with eyes closed. It was further confirmed by the observation that the direction of the slow component of the nystagmus was toward the right side. Nystagmus was marked — especially when the patient looked to the left side (corresponding to the quick component).

Unfortunately, caloric tests were not carried out, presumably because of the perforated eardrum. However, in such cases otologists are beginning to perform caloric tests with a sterile saline solution to which antibiotics have been added.

Continued

Otogenic Lesions

This patient had multiple childhood ear infections and a hemorrhage from the right ear while flying in 1942. He also had pulsatile noises in both ears and impaired hearing on the right.

If he had had a cholesteatoma in the middle ear (which extended into the dura) this should have been visible in the plain films of the skull. He could have had a chronic brain abscess with cerebellar signs, as this can occur even without increase of cells or protein in the cerebrospinal fluid. It is also possible that arachnoiditis in the cerebellopontine angle could have produced this clinical picture.

In the later part of the hospital course there was weakness of the right arm and diminution of graphesthesia (presumably in the right upper limb). These signs probably resulted from compression of the left cerebral peduncle against the sharp edge of the tentorium, having been displaced by a mass from the right side in the region of the tentorial notch. They are less likely to have resulted from extension of a left frontal mass, where one would have expected some facial weakness first. Weakness of a limb occurs as a late sign in about 5% of posterior fossa tumors.

Non-Neoplastic Infratentorial Lesions

One must consider Arnold-Chiari malformation, but this presents as increased intracranial pressure primarily in the age group 15 to 25 years, and there are usually x-ray changes in the region of the foramen magnum and upper cervical spine. Aqueductal stenosis can occur at any age but particularly in the younger group. In basilar meningitis with communicating hydrocephalus there would not be the gross discrepancy between ventricular and spinal fluid protein. Furthermore, the Ayala index would be high rather than low. Ependymitis with blockage of the foramina of Magendie and Luschka and a dilated fourth ventricle or a cyst through the tentorial notch — perhaps from a lateral ventricle — are likely to occur in younger people.

Diffuse Hypertrophy of the Cerebellar Cortex

In 1955 Oppenheimer summarized eleven cases from the literature in which there was a progressively enlarging mass in the cerebellum. There were grossly expanded folia but there was no definite neoplastic mass. Microscopically there were atypical nerve cells, a reduction of central white matter and absence of recognized granule and Purkinje cells. One case history lasted ten years. The spinal fluid protein was described in two of these cases and was not higher than 55 mgm.%.

Ischemic Edema of the Cerebellum

This occurs usually in older people with arteriosclerosis. It is not associated with chronic symptoms but may simulate a malignant cerebellar tumor.

Infratentorial Tumors

The ataxic gait for four or five months strongly points to a posterior fossa lesion.

Jefferson's experience with posterior fossa tumors in the fifth decade of life included forty-eight cases of acoustic nerve tumors, fifteen hemangiomas, seven astrocytomas, and seven metastatic lesions.

Intra-axial Tumors

Could this be a lesion of the mid-brain? There was no disturbance of the pupils and none of the extra-ocular movements. Could it be a pontine glioma? There were no other cranial nerve palsies and the spinal fluid protein was high.

Intraventricular Tumors

Could this be a lesion of the fourth ventricle with invasion of the dentate nucleus or peduncles? There was no nuchal rigidity with retraction of the head and no rise in ventricular protein. These tumors may also be associated with cranial nerve palsies.

Extra-Axial Infratentorial Tumors

Usually with meningiomas of the tentorial notch there is increased intracranial pressure with headache and vomiting. The symptoms may last up to fifteen years. Nevertheless, two thirds of the cases of meningiomas have symptoms of three years or less. There may be disorder of balance and other cerebellar signs, nystagmus, stiff neck and hyperreflexia. Occasionally there are diminished hearing, changes on caloric testing, and fifth nerve involvement. Meningiomas of the convexity of the cerebellum appear primarily as increased intracranial pressure without localizing signs. Most cases of meningioma of the posterior fossa have a low protein content of cerebrospinal fluid. The differential diagnosis depends on special studies, especially pneumoencephalograms and vertebral angiograms.

Hemangiomas

The history is usually under two years in these tumors of the cerebellar hemisphere. They occur in the age group 20 to 50 and are more common in men than women. Cerebellar disturbances of gait and station are common, along with nystagmus.

Posterior Fossa Dermoid Cysts

These tumors usually present with the clinical picture of vascular accident or sub-acute meningitis, but a clue may be oily cerebrospinal fluid containing cholesterol. Rarely, the symptoms and signs are those of progressive internal hydrocephalus without symptoms of meningitis. These tumors lie in the midline and have an extremely slow evolution of symptoms. X-rays may reveal abnormalities of the cervical spine, associated with truncal ataxia without incoordination of the limbs.

An Aneurysm of the Basilar Artery appeared in the cerebellopontine angle and gave all the symptoms typical of an eighth nerve tumor, including a high protein content of the spinal fluid, enlargement of the internal auditory canal, progressive deafness and tinnitus.

A Neurinoma of the Fifth Nerve arising from the Gasserian ganglion and extending down through the tentorial notch is usually recognized by an enlargement of the foramen ovale and/or the foramen rotundum.

Continued

Usually there is some atypical trigeminal pain or paresthesia and it is said that there is always corneal anesthesia. These cases may be associated with a high protein content of the cerebrospinal fluid.

Tumors of the Glomus Jugulare arising in the dome of the jugular bulb may appear as a polyp in the external auditory canal. Its intracranial extension may be marked by deafness, tinnitus, vertigo and otorrhea. There may also be involvement of the sixth or seventh nerves as well as dysphonia and dysphagia. The x-rays usually reveal bony defects.

Ependymomas of the Cerebellopontine Angle are rare tumors which arise within the lateral recess of the fourth ventricle and emerge from the foramen of Luschka. Clinically they may be indistinguishable from other masses in the angle. However, in one personal case there was involvement of the ninth and twelfth cranial nerves with sparing of the fifth, seventh, and eighth.

Acoustic Nerve Tumor

As indicated by Jefferson, in middle age the most common tumor of the posterior fossa is an eighth nerve tumor. This is a benign tumor which must be considered pre-eminently in differential diagnosis. Commonly there is headache which may be frontal. One must be especially cautious not to ascribe eighth nerve symptoms to pre-existing ear disease, when

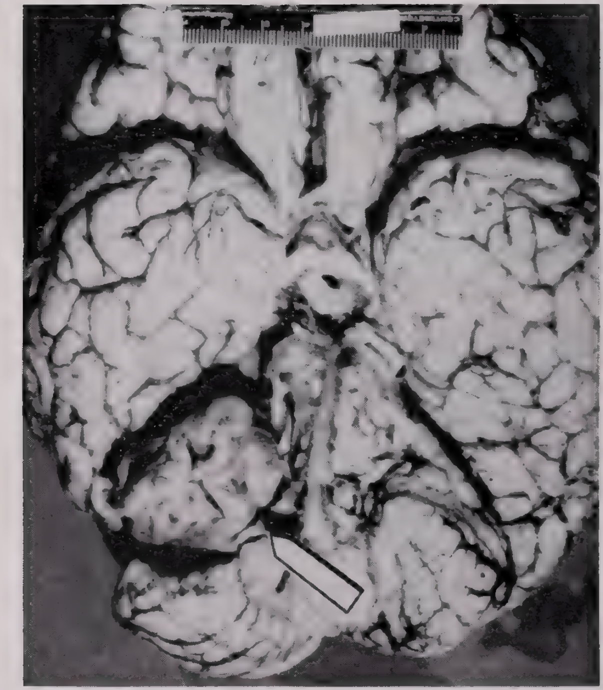

Fig. 4 — Base of brain with right acoustic neurinoma *in situ.*

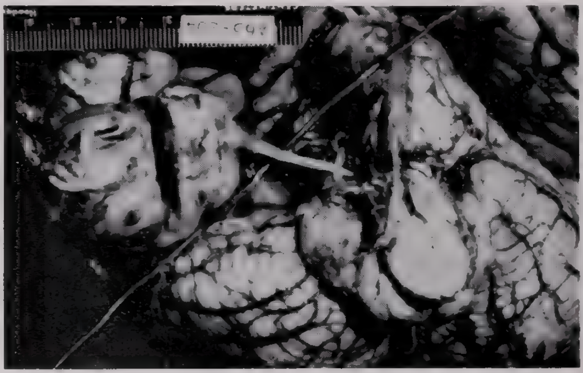

Fig. 5 — Tumor arising from eighth nerve, displaced from its bed.

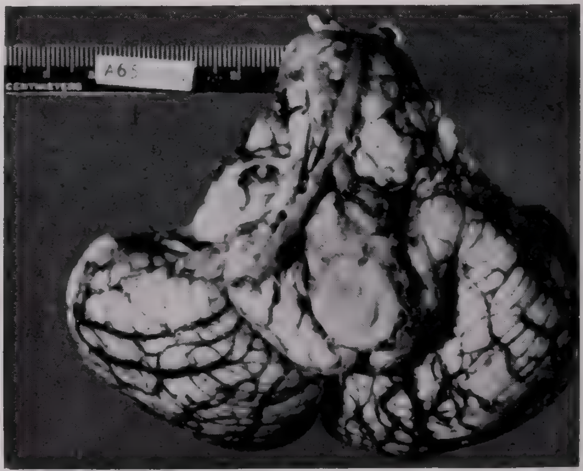

Fig. 6 — Bed of tumor in brain stem and lateral lobe of cerebellum. Extreme herniation of cerebellar tonsils.

there is evidence of increased intracranial pressure. The history of former ear disease may prove to be seriously misleading. Characteristically, cerebellar signs in eighth nerve tumors affect gait and produce nystagmus with a rapid phase to the opposite side.

The cerebrospinal fluid pressure was elevated in 60% of the cases of Pool and Pava, and the protein content was over 50 mgm. in 97% of the cases and over 200 mgm. in 45% of the cases. Of all brain tumors the acoustic nerve tumor is most prone to have an elevation of the total protein content of the cerebrospinal fluid.

Concerning the long history, ten of Pool and Pava's 122 cases had unilateral hearing difficulty for 10 to 25 years. Headache from one to ten years was characteristic. The erosion of the porus acousticus occurs in only about 60% of the cases, and one must not be misled by normal plain skull films.

Summary

This is a 43-year-old man with 10 years of bifrontal headaches, five years of a pulsatile noise in both ears, one year of blurred vision, four months of loss of balance where examination revealed bilateral papille-

dema, increased cerebrospinal fluid pressure, greatly increased cerebrospinal fluid protein content, with staggering to the right and nystagmus to the left.

The evidence is strong that this is a right-sided cerebellopontine angle tumor, most likely arising from the eighth nerve.

Pathology

Dr. J. Albert Schaefer*

Autopsy findings in this puzzling case were most interesting. Intracranially there was a large right acoustic (8th nerve) neurinoma which measured 4 × 3 × 2 cm. and lay in the classical location at the cerebellopontine angle. The tumor impinged considerably upon and indented the right cerebellar hemisphere and to a lesser extent, the pons. Figures 4, 5 and 6 show the external aspects of the tumor and its relationships to the pons and cerebellum. The cut surfaces of the tumor were pale gray to yellowish and tannish-gray and moderately firm, irregularly mottled and disrupted with reddish-brown hemorrhage and focally degenerated and softened tissue, as shown by Figure 7. Gross examination also revealed the Spitz valve in place, and there was moderate hydrocephalus secondary to the extra-axial tumor mass compressing the brain stem and compromising the aqueduct of Sylvius. There were also foci of recent and remote intracerebral hemorrhage in the left parieto-occipital region and subependymally along the left lateral ventricle, respectively, probably secondary to the increased intracranial pressure. Figures 8 and 9 show both the Spitz valve and the hydrocephalus as well as the foci of intracerebral and subependymal hemorrhage.

Microscopically the tumor showed a rather typical histologic appearance, principally of Antoni type A pattern with palisading of nuclei and occasional Verocay bodies, but also with scattered foci of Antoni type B degenerative pattern. The general microscopic pattern of the tumor is shown in Figure 10.

The cause of death in this interesting case of cerebellopontine angle tumor was sepsis, supported morphologically at autopsy by the presence of a periurethral abscess with accompanying suppurative prostatitis and cystitis, and also by acute ulcerative and hemorrhagic tracheobronchitis with retained purulent secretions, partial bronchial obstruction, and bronchopneumonia of the right lung.

Grand Rounds

Management of Combined Organic and Emotional Factors in a Post-Partum Psychosis

DAVID B. ROBINSON, M.D.
Syracuse, New York

Dr. David B. Robinson:*

The reasons for reporting the present unusual case of post-partum psychosis are several. The case presents a combination of toxic and emotional etiologic factors in the development of a psychotic reaction. It is believed that since both factors (psychic and somatic) were recognized in this case and treated with equal intensity, the clinical course was a dramatically favorable one. Furthermore, this case provides a backdrop for brief discussion of the development and handling of many acute psychotic reactions observed in general hospitals and therefore pertinent to a general medical audience.

Case Report

Dr. Donald T. Brooks, Jr.:**

The patient is a 25-year-old gravida IV, Para III female. Catamenia 13 × 32 × 5. She was close to her expected date of confinement.

Present Illness

Nine days prior to the present admission the patient had been referred into Syracuse Memorial Hospital from a neighboring hospital with a diagnosis of possible abdominal pregnancy or placenta praevia. Sterile pelvic examination done here at that time

Continued

showed a large, cystic, extrauterine mass in the cul-de-sac, displacing the cervix anteriorly and superiorly behind the symphysis pubis. The cervix was closed and uneffaced. The fetus was in transverse presentation. X-rays accompanying the patient were interpreted by the Syracuse Memorial Hospital radiologist as showing an intrauterine pregnancy with transverse presentation and the presence of a soft tissue mass in the cul-de-sac, the exact nature of which could not be determined. The placenta could not be visualized. Because of the stage of gestation the patient was returned to the neighboring city hospital to be re-admitted to Syracuse Memorial Hospital after two weeks for further evaluation.

The patient had had a relatively uneventful prenatal course. Her blood pressure had remained normal and she had gained a total of 20 lbs. in weight.

Her first pregnancy had resulted in fetal demise at the sixth month of gestation. Two months after the fetal death, mild uterine contractions developed, she was hospitalized and told that she was not in labor. She was given an enema and placed upon the bed pan. While expelling the enema, the macerated, decomposing fetus was passed into the bed pan while the patient watched the entire procedure unattended and terrified. Two subsequent pregnancies were normal with spontaneous deliveries at term.

Past Medical History

Essentially negative except for a delirious episode with fever of 104° associated with bilateral otitis media at age 19. The patient had had psoriasis for the past ten years with alternating remissions and exacerbations.

Family History

Patient's mother died at age 49 of cancer of the uterus. Father died at age 51 of coronary artery disease. No other familial diseases.

Social History

The patient has been married for seven years. She revealed no unusual habits, does not use drugs, narcotics, or alcohol to excess.

Physical Examination

The significant physical findings on admission included: BP of 120/80, psoriasis of the legs, arms, abdomen, chest and back. There were no abnormalities of the heart or lungs. The abdomen showed the fundus to be approximately 30 cm. with caliper measurements. The fetus appeared to be in a transverse presentation with the fetal heart heard in the right upper quadrant. A sterile pelvic examination done in the morning following admission showed no change in condition except that the fetus was now in breech presentation.

Laboratory Data

On admission: Hgb. 10.4 gm.%; hematocrit 36 vol.%; wbc 9,000; urinalysis — negative.

It was decided that with the fetus at term and with a large obstructing mass in the pelvis completely displacing the cervix, delivery would best be accomplished by cesarean section with exploration of the pelvis and removal of the mass if feasible. A laparo-trachelotomy was performed under local anesthesia, and a 6 lb. 14 oz. infant was delivered which breathed and cried spontaneously. Following repair of the uterine incision, a large, right ovarian cyst (12 × 14 cm.) was found to be completely replacing the right ovary. The cyst was removed and the abdomen was closed in routine fashion.

The patient ran a completely normal postoperative course until the fourth postoperative day when her temperature spiked to 100.4°. On the sixth postoperative day the temperature again rose to 100° on two occasions. On the seventh postoperative day she had a slight chill which she did not report to the nursing staff at the time. On the morning of the eighth day the patient was told by the pediatrician that the baby had a congenital heart anomaly, the exact nature or seriousness of which had not yet been determined. Two hours later the patient had a shaking chill and her temperature spiked to 103.8°. She was seen promptly by a member of the house staff who, upon palpating her abdomen, asked, "Does it hurt?" Shortly thereafter the patient became deliriously maniacal, reiterating the phrase she had just heard, "Does it hurt?" She thrashed wildly in bed and screamed that she was about to die. She could not identify those around her. She said that while at the previous hospital God told her in a dream that she was going to die. She pleaded with the attendants to believe her and shouted that she knew we wouldn't believe her. She alternated quickly between extreme moods of excitement and depression. She told the doctors not to try to calm her and not to tell her that she was all right because she knew that she was going to die. She wanted messages given to her husband and then she said not to tell her husband that she was going to die for that would make him feel very bad. She thrashed, screamed and kicked out at the various attendants. At times her sentences were completely incoherent and she seemed to be out of contact with those around her. She also said that "they" were in contact with her and told her "many things." Who "they" were remained obscure, but she was evidently referring to hallucinations. On one occasion she appeared to be subjectively experiencing precipitous delivery. She called out — "Here it comes! The head's being born now!"

Attempts at quieting and reasoning with the patient were completely unsuccessful. She was given promazine hydrochloride* 100 mg. I.V. and 100 mg. I.M. which she resisted, accusing the staff of trying to kill her. The Psychiatry Department was notified and immediately a member of the staff came to see her.

Dr. Robinson:

When I arrived the patient was lying quietly in bed with an aide sitting expectantly in a chair facing her from a position near the foot of the bed. The frightened roommate had left the room and had precipitously decided to leave the hospital. An atmosphere of anxiety, fear, and consternation permeated not only the patient's room but also the hallway and the nurses' station where the facts relating to the sudden explosion were made known to me by the nurses — including those who had been recipients of the patient's abuse and kicks a short time earlier.

The patient was slightly flushed, perspiring and appeared somewhat dazed and frightened. After introducing myself, I said, "You've been frightened and mixed up. I want to help you with your worries and those feelings that make you afraid and confused." She immediately and correctly identified me as a psychiatrist and asked if she were crazy. I agreed that I was a psychiatrist and repeated that she had been very mixed up. (In this way I confirmed the suspicions of and aligned myself with the still functioning, healthy or observing aspect of her ego.) In the ensuing hour's interaction, certain comments of the patient were emphatically repeated by her. Other remarks assumed special significance in their context. Concurrently, I made observations on the patient's mental status. Since it is neither possible nor desirable to give a verbatim account, extracts are presented, accompanied by some of the thoughts that occurred to me as to possible meanings of her psychotic productions.

Repeated over and again by the patient with much urgency at first was: "Tell my husband — *they don't know anything here*! That's all

---

*Sparine.®

Continued

that's important! I must suffer — it's terribly painful — no one knows — God tells me that I must die — It's terrible!" (This seemed to be an attempt to deny something serious about which she had a great sense of guilt and, hence, must suffer and die. Was she reacting to the knowledge of her baby's congenital heart disease? This was the information she had learned for the first time that morning preceding the psychotic break. It is known that mothers often react to defects in their babies with much guilt,[3] feeling that they are responsible.)

The patient then identified herself with a character in a book she had read who "suffered terribly and died" despite the care of a fine doctor. I asked, "Why do you feel you must die?" She replied, "I can't tell you — I won't. When the pain is unbearable — if I say the word I won't die. But if I tell you the word, it won't work and I'll die —. I don't want to." (Here was evidence of regression to magical omnipotence and, more important, it showed the struggle of the healthy aspects of the ego to survive against the onslaught of her guilt.) "I won't tell you — I don't want my husband to be embarrassed or ashamed of me." She hallucinated actively — heard voices and ignored me. "I think it's God — Yes, it's God telling me I must die." She waved me away when I asked a question. (I felt at this point that she was retreating from me and from the observing ego. I decided to intervene in behalf of the latter.) I spoke authoritatively, "You are *not* going to die. You have a fever from an infection in your womb. The fever has you mixed up right now but you are not going to die!" She replied, "I'm not? — But then I must suffer — a terrible disease. If I could just tell you — but I can't." At this point she asked the aide and two doctors who had come in earlier to leave. She still could not bring herself to tell me the name of the disease — which proved to be "the word" she referred to earlier. I offered her paper and pencil which she accepted and then wrote the word, LEPROSY. — "Like she had in the book — it was terribly painful at the end." (The patient has had psoriasis since puberty. Such patients often have conscious or unconscious fantasies of their disease representing a punishment for evil or "sinful" deeds or thoughts. Biblical references speak of lepers as "unclean" — implying sinfulness or devilishness. Had the guilt over the imperfect child reawakened an earlier parallel sense of guilt over her psoriasis? If so, *could the concern with leprosy, i.e., psoriasis, be a screen for a less tolerable and currently more anxiety-laden concern about the defective infant?)* I decided to test this hypothesis. I told her, "You feel that you have done something terrible and deserve to suffer — something very evil." "That's right," she replied. I continued, "Perhaps you haven't — perhaps you just feel that you have. I wonder if the leprosy idea doesn't come from your psoriasis. They are totally different — leprosy is caused by a germ — something like tuberculosis — psoriasis is not. But, most important, *you feel wicked*. Why?"

At this point there was a significant transition in her. She seemed in better contact and showed more appropriate affect. "They told me I shouldn't go on the ladder." She then told of climbing a ladder during the fourth month of her pregnancy to remove plastic window screens. "They said I'd hurt myself or the baby" — (a precipitating source of the guilt?) — "but it didn't hurt — I felt no strain." Her eyes filled with tears. There were no more hallucinations after this time.

I again supported the healthy ego with tone of voice and an authoritative educational approach trying to alleviate her illogically founded guilt. "So you feel it's your fault that the baby has a defective heart. This is what you feel so guilty about. You feel that those who told you climbing the ladder would harm the baby were proven to be right. They aren't!" I then discussed prevalent folklore about congenital defects in general, and went on to discuss the known facts of congenital heart defects *in particular*, always emphasizing the absence of blame for the mother. I told her about the effects of German measles in the pregnant mother during the first trimester of pregnancy and again observed that it was not the mother's *fault* if she acquired measles at this time. Here she mused with some apparent relief, "Maybe I had German Measles."

Feeling that I should interject a positive note of hopefulness, I then discussed the difficulty of accurately assessing murmurs in the newborn and the physiologic changes in circulation from the fetal state to the neonatal period. Not wanting to foster what might turn out to be false hopes, I then talked about the marvelous advances in cardiac surgery which can now correct certain anomalies. The patient listened attentively and asked appropriate questions. Then she commented spontaneously, "I feel better. I guess I was pretty worried about this and didn't realize it." At this time she could recall my name when asked although I had inquired unsuccessfully at least five times previously during the interview. Each time I had again given her my name. By the end of the interview she was less flushed and her fever had subsided somewhat. Early in the interview she had been disoriented in time although not in place. By the end of the hour her temporal orientation was intact.

With Dr. Brooks, a program of management was then outlined to combat both toxic and emotional determinants of the psychotic reaction. Medical measures included: (1) immediate establishment of cervical drainage of the uterus; (2) simultaneous culture of uterine contents for sensitivity studies; (3) continued broad-spectrum antibiotics; (4) aspirin gr. XV, q4h; (5) force fluids; (6) temperature readings — with alcohol sponge baths for temperature elevation.

Measures were also taken to control the patient's anxiety: (1) The complete situation (medical and psychiatric) was discussed with floor nurses, nursing supervisor, OB residents and nurses' aides. (2) The husband who arrived after the storm had abated was informed in simple direct terms of the nature of his wife's reaction and the determining factors. His aid was enlisted to encourage his wife to talk freely of her feelings, particularly concerning the infant. (3) Knowing the tendency to recurrence of delirious states (especially at night) all attendants were instructed in methods of helping the patient to maintain orientation by repeated sensory contacts through visual, auditory and tactile routes. A night light was ordered for the room. The husband was requested to stay overnight since his familiar face and voice would be especially reassuring and meaningful to her in the event of a return of a clouded sensorium. (4) Oral promazine 50 mg. q4h was provided for additional control of anxiety. A tranquillizer of this nature seemed preferable to a sedative or hypnotic which might increase the clouding of consciousness. (5) The patient was to be assured insofar as possible by factual reporting concerning the status and welfare of her infant.

Continued

Dr. Brooks:

Her temperature dropped to 100.6° and then to 99.6°. However, at approximately 11:00 p.m. it again spiked to 102.6° and the patient again became delirious, uttering the same words and making the same accusations as she had previously. She was sponged and again given 100 mg. of promazine I.V. and I.M. Blood cultures were again drawn. Within a short while she quieted down and became aware of her surroundings.

The patient was kept on chloromycetin and aspirin over the next three days. The temperature never rose over 101.4° and she had no further episodes of delirium. The uterine culture showed members of the coliform group. The urine culture as well as repeated urinalyses were negative. Blood cultures failed to grow out any organisms. The wbc. never rose above 9,000. Because the temperature continued to spike to 101° at least once daily for the next three days, the antibiotics were shifted to 600,000 units of penicillin and 0.5 Gm. of streptomycin twice daily. On the twelfth postoperative day, her temperature rose for the last time. She was discharged on the fifteenth postoperative day on tetracycline 250 mg. and 200 mg. of Mol-Iron® three times a day. On discharge the hemoglobin was 9.3 Gm. %; hematocrit 32 vol %; wbc. 7,800 with a normal differential. The patient was discharged to the care of her private physician at home.

Several days after returning home a pyelitis developed with frank pus in the urine. The patient had fever to 106° for three days with no recurrence of a delirious reaction. The infant had several cyanotic episodes at home and was eventually evaluated in a medical center. Surgery was attempted but the infant unfortunately succumbed. The mother has withstood these stresses and this tragic outcome successfully without an emotional decompensation.

Discussion

Dr. Robinson:

Although the emphasis of this paper is on the psychological aspects of an illness, the obstetrical data (in the physical sense) have been reported in detail. These details convey to the reader an appreciation of the patient's preoperative stresses generally and specifically: the large number of examinations, the uncertainty, the expectant waiting, the trips to and from Syracuse, finally culminating in surgical intervention. In addition, the patient had been aware early of the possible diagnosis of abdominal pregnancy, had read about the condition and knew the serious potentiality of this condition. In the face of all of these anxiety-producing circumstances, her psychological defense mechanisms remained clinically intact until the eighth postoperative day. She had been able to relate in a friendly way to nurses, doctors and fellow patients within the hospital. She had not exhibited the schizoid, tentative modes of relating to people often apparent in the patient who is prone to develop a post-partum schizophrenic-type reaction.

The obstetrical data further provide important information in evaluating and interpreting the toxic febrile aspects of the psychotic reaction which developed. Past obstetrical history revealed an exceedingly traumatic experience related to the patient's first pregnancy. Two normal obstetrical experiences occurred subsequently. These historical data are significant in that any new life experience is approached with emotional overtones and expectancy determined by the summation of emotional responses to previous similar experiences. It is worth noting in this connection that a nurse commented spontaneously that this patient was more tense than the usual patient about receiving and expelling her preoperative enema. Otherwise she had been a "good patient." This observed response was probably conditioned by the highly traumatic experience of her first pregnancy when she expelled, unattended, a macerated, dead fetus into the bedpan following administration of an enema.

The history of a previous febrile delirious state associated with a fever of 104° suggests a lower than usual threshold for the development of a delirious reaction. Emotional factors surrounding this earlier delirious state are unknown except for the fact that at the time of the reaction she was far from home in Europe with her husband. The fact that she did not develop a delirious reaction after returning home (when her temperature rose to 106° for three successive days) again supports the hypothesis of multiple (psychologic as well as febrile-toxic) causative factors producing the psychotic reaction she experienced in the hospital.

In retrospect, it is recognized that in the face of a developing endometritis and probable incipient delirium state, the patient was presented with emotionally traumatic information about her infant. In the absence of the toxic state accompanying the endometritis, the patient's usual psychological modes of adaptation might well have permitted her to deal with the emotionally traumatic events without a psychotic break. Overwhelmed by the combination of toxic impairment of mental functioning, the summation of anxiety from events leading to surgery, and finally the emotional reactions to knowledge of the baby's abnormality, the ego gave way to explosive, psychotic expressions of affect. The language and symbols used were identical with the symbol system of dreams — namely, the language of the unconscious. In the case report presentation, an attempt has been made to translate this language in context from the manifest to the latent content. Just as the internist interprets manifest shadows on an x-ray film, the psychiatrist finds hidden meanings in dreams or psychotic productions. It is postulated that this patient's psychotic state was brought to a rapid resolution by re-establishing lines of communication and dealing directly with the latent content of her words and actions. This in turn permitted constructive handling of the immediate sources of her overwhelming anxiety and guilt. As soon as the anxiety and guilt were allayed, the psychosis subsided. The participating roles of medication are recognized. The aspirin helped to reduce the fever and the promazine undoubtedly added its quieting effect.

The importance of the message contained in the first delusion or hallucination in schizophrenic patients has been stressed by Beckett et al.[1] In their study it was observed that patients' nuclear conflicts were often expressed in condensed symbolic fashion. Freud[2] pointed out that dreams contain a condensation of current feelings (emotional and somatic) with feelings from the past. He observed further that in most dreams a hidden wish is expressed. Within the dream or psychotic production the psychiatrist looks for the elements of wish fulfillment. These were the main guiding principles in understanding the present patient's psychotic verbalizations. The parenthetical comments interspersed in the dialogue of the

Continued

case report demonstrate the use of these basic principles. Similarly, one can consider the possible meaning of the patient's delusional experience of the birth of a baby at the onset of her psychotic break. Does this represent the fulfillment of a wish to give birth to her baby "normally" rather than by cesarean section (abbnormally) and, by extension, to produce a "normal" rather than an "abnormal" infant? Such an explanation has the merit of fitting the overall pattern of her productions as "understood" from the same theoretical framework. Her response to the therapist's approach suggests validity of the working hypothesis.

In the classical investigations of Benedek and Rubinstein[3] the effects of monthly hormonal shifts in women were observed in the dream content. The sudden and dramatic hormonal changes following parturition may well participate in the development of untoward psychological reactions in those individuals who have a specific psychologic vulnerability. It is apparent that hormonal changes *alone* do not explain these reactions since the majority of mothers have no untoward reaction after parturition.

The rationale for the specific medical treatment of the endometritis needs no elaboration to the readers of this journal.

Measures outlined to help control the patient's anxiety warrant some further discussion, especially since they apply to reactions to many types of acute and chronic organic brain impairment. Patients who consciously or preconsciously sense impairment of their mental faculties characteristically exhibit much fear and dread. Their inability to think clearly, to orient themselves, or to remember recent events causes much consternation and anxiety. The physician who attempts to reassure the patient that "all is well" may only increase the intensity of the patient's reaction. The patient may then feel that no one else is aware of the terrible changes within him. He may also feel that he is being "protected" from a "truth" that is too terrible to be faced directly. For these reasons it is preferable to talk about the confusion directly, thus implying that it is recognized, not to be feared, and can be treated successfully.

Because of the mental impairment, it is helpful to increase the input of sensory cues which will assist the patient to remain oriented in time, place and person. The patient should be addressed by name, repeatedly told *where* he is and why, because he soon forgets. Familiar persons or objects in the room are helpful. A radio or TV set increases familiar auditory cues for orientation. (Care should be taken in appropriate selection of programs.) A room light helps for more rapid visual orientation at night when not only visual but also auditory cues are usually reduced.

Families as well as professional personnel not accustomed to dealing with psychiatric problems may become anxious, particularly when the patient's own fear and anxiety results in behavior that is disruptive to the hospital floor. Anxiety of personnel and/or family members readily feeds back to increase the patient's anxiety. For this reason, time spent allaying the anxiety of those around the delirious patient is well spent. Explanations and specific suggestions for constructive measures to both hospital personnel and family are helpful in this regard.

Summary

1. A patient with a post-partum psychosis caused by a combination of toxic and emotional factors has been presented.

2. The specific medical and psychologic treatment measures used in this case have been outlined and discussed.

3. General measures to help control anxiety in organic confusional states have been discussed.

Kartagener's Syndrome

This syndrome consists of the triad of chronic sinusitis, bronchiectasis, and situs inversus. It was first described by Kartagener who reported a group of cases in 1933. The syndrome may begin early in neonatal life. In most instances symptoms date back to childhood. Ninety per cent of cases were observed before the age of 15 years. The condition has been observed to occur in siblings and in identical twins. One hundred and five cases have been recorded in the literature (Krejci and Kleiman).

The pathogenesis of this syndrome depends upon the congenital factors of situs inversus, agenesis of sinuses, and a deformity of bronchi, as well as upon the acquired factor of upper and lower respiratory tract infection. There may be situs inversus totalis with transposition of the heart and the entire gastrointestinal tract, or there may be dextrocardia alone. Roentgenograms show agenesis of the frontal sinuses and either congenital absence or poor development of all paranasal sinuses. Nasal polyposis is frequently observed.

The cause of the bronchiectasis has given rise to considerable speculation. Its occurrence in siblings suggests a genetic predisposition. The incidence in patients with dextrocardia or transposition of the viscera is greater than among the general population. Suggested causes include (1) congenital weakness of the bronchial wall, and (2) abnormal position of the great vessels, which interferes with normal bronchial drainage. Because bronchiectasis is the greatest factor in the morbidity of this syndrome, it is important that all patients who have dextrocardia or situs inversus should have roentgenograms of the sinuses and chest and bronchograms if bronchial symptoms are present.

Intensive therapy with antibiotics is indicated for the recurrent respiratory infections. If bronchiectasis is present, resection is the procedure of choice.

SPASTIC URETERITIS
BLADDER SPASM

are relieved by
direct musculotropic action
with.....

Trocinate®

BRAND **THIPHENAMIL HCl**

Available in 100 milligram pink sugar-coated tablets.

The high therapeutic index permits dosage sufficient to relieve spasm promptly.

Administer 4 tablets every 4 hours until relief is constant, then adjust maintenance dosage.

Trocinate BRAND THIPHENAMIL HCl

Directly relaxes smooth muscle spasm
Combats hypermotility
Non-mydriatic, may be used in glaucoma

Sixteen years of clinical use, with absence of untoward effects, has established the safety and effectiveness of Trocinate.

Trocinate is metabolized in the body and completely eliminated, which is a safety factor. Dosage must be sufficient to maintain the therapeutic blood level.

In Memoriam

Death is like thunder in two particulars: We are alarmed at the sound of it, and it is formidable only from that which preceded it. — Colton

RUDOLPH LOGEFEIL, M.D.

Dr. Rudolph C. Logefeil, 72, former chief of Staff at Fairview Hospital and medical director for the Evangelical Alliance Mission, died September 17. He was a graduate of the University of Minnesota and had done graduate and medical studies at Johns Hopkins University, Baltimore, Maryland, and Columbia University, New York.

Dr. Logefeil was a board member of the Fuller Theological Seminary and Oak Hills Fellowship, Bemidji; a member of the Hennepin County Medical Society and American Medical Association and an Associate Member of the Minnesota State Medical Association.

He is survived by his wife, two daughters and a son.

JOSEPH F. BICEK, M.D.

Dr. Joseph F. Bicek, 67, St. Paul physician and surgeon, died September 9, of injuries suffered in a fall in his home. Born in LeSueur, Dr. Bicek lived in St. Paul forty-five years.

He was a member of the Ramsey County Medical Society, Minnesota State Medical Association, American Medical Association, American College of Obstetrics and Gynecology and a fellow of the American College of Surgeons. He was a 1921 honor graduate of the University of Minnesota Medical School and a former instructor of obstetrics and gynecology at the University.

He is survived by his wife and a daughter.

WILLIAM F. MENOLD, M.D.

Dr. William F. Menold, 52, St. Paul obstetrician and gynecologist, died October 17. Born in St. Paul, he lived there all of his life.

Dr. Menold was a member of the Ramsey County Medical Society, American Board of Obstetrics and Gynecology, American Medical Association and the Minnesota State Medical Association.

He is survived by his wife, two daughters and a son.

RICHARD B. GRAVES, M.D.

Dr. Richard Graves, 58, Red Wing physician, died suddenly October 15 of a heart attack at his home in Naples, Florida. Born in Ely, Dr. Graves obtained his medical degree from the University of Minnesota.

He was a member of the Goodhue County Medical Society and the American Medical Association and an Associate Member of the Minnesota State Medical Association.

He is survived by his wife and two daughters.

FREDERICK W. BEHMLER, M.D.

Dr. Fred W. Behmler, 71, a former state senator and a practicing physician in Morris for forty years, died November 9. A native of Jordan, Dr. Behmler attended Carleton College and graduated from the University of Minnesota Medical School.

He was a former president of the Minnesota State Board of Health, former first vice-president of the Minnesota State Medical Association, and had been very active in the Boy Scouts. He was a member of the West Central Minnesota Medical Society, American Academy of General Practice, American Medical Association, and an Associate Member of the Minnesota State Medical Association. Dr. Behmler was one of the prime movers in the campaign that resulted in the establishment of the University of Minnesota, Morris, and Behmler Hall on the UMM campus was named in his honor.

He is survived by his wife, a son and a daughter. Dr. Raymond Behmler of Minneapolis is his brother.

IRWIN L. OLIVER, M.D.

Dr. Irwin L. Oliver, 62, Graceville physician, died November 21, after a lengthy illness. Born in Graceville, Dr. Oliver attended Shattuck School in Faribault and received his medical degree from the University of Illinois.

He and his father, the late Dr. C. I. Oliver, practiced together until Dr. Irwin Oliver retired in 1962 and turned the Oliver Clinic over to the City of Graceville. This father-and-son team also developed the West Central Minnesota Hospital which later was transferred to the Missionary Benedictine Sisters.

He was a member of the West Central Minnesota Medical Society, American Medical Association and the Minnesota State Medical Association.

He is survived by his wife, two daughters and two sons, one of whom is Dr. Robert I. Oliver of Jackson, Mississippi.

Many overweight patients can benefit from the appetite control provided by the sustained anorexigenic-tranquilizing action of BAMADEX SEQUELS: anorexigenic action of amphetamine; tranquilizing action of meprobamate; prolonged action through sustained release of active ingredients.

Bamadex® Sequels®

DEXTRO-AMPHETAMINE SULFATE (15 mg.) WITH MEPROBAMATE (300 mg.) SUSTAINED RELEASE CAPSULES

to help establish a new dietary pattern

Contraindications: Dextro-amphetamine sulfate: in hyperexcitability and in agitated prepsychotic states. Previous allergic or idiosyncratic reactions to meprobamate.

Precautions: Use with caution in patients hypersensitive to sympathomimetic compounds, who have coronary or cardiovascular disease, or are severely hypertensive.

Dextro-amphetamine sulfate: Excessive use by unstable individuals may result in psychological dependence.

Meprobamate: Careful supervision of dose and amounts prescribed is advised, especially for patients with known propensity for taking excessive quantities of drugs. Excessive and prolonged use in susceptible persons, e.g. alcoholics, former addicts, and other severe psychoneurotics, has been reported to result in dependence on the drug. Where excessive dosage has continued for weeks or months, reduce dosage gradually. Sudden withdrawal may precipitate recurrence of preexisting symptoms such as anxiety, anorexia, or insomnia; or withdrawal reactions such as vomiting, ataxia, tremors, muscle twitching and, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, reduce dosage and avoid operation of motor vehicles, machinery or other activity requiring alertness. Effects of excessive alcohol consumption may be increased by meprobamate. Appropriate caution is recommended with patients prone to excessive drinking. In patients prone to both petit and grand mal epilepsy meprobamate may precipitate grand mal attacks. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side Effects: Overstimulation of the central nervous system, jitteriness and insomnia or drowsiness.

Dextro-amphetamine sulfate: Insomnia, excitability, and increased motor activity are common and ordinarily mild side effects. Confusion, anxiety, aggressiveness, increased libido, and hallucinations have also been observed, especially in mentally ill patients. Rebound fatigue and depression may follow central stimulation. Other effects may include dry mouth, anorexia, nausea, vomiting, diarrhea, and increased cardiovascular reactivity.

Meprobamate: Drowsiness may occur and can be associated with ataxia; the symptom can usually be controlled by decreasing the dose, or by concomitant administration of central stimulants. Allergic or idiosyncratic reactions: maculopapular rash, acute nonthrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever, transient leukopenia. A case of fatal bullous dermatitis, following administration of meprobamate and prednisolone, has been reported. Hypersensitivity has produced fever, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, stomatitis, proctitis (1 case), anaphylaxis, agranulocytosis and thrombocytopenic purpura, and a fatal instance of aplastic anemia, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity, usually after excessive dosage. Impairment of visual accommodation. Massive overdosage may produce drowsiness lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Abstracts, Briefs and Commentaries

NUTRITIONAL DEFICIT AFTER GASTRECTOMY

Weight loss is a cardinal sign of under-nutrition, and it was found that approximately 50 percent of post-gastrectomy patients suffered some degree of nutritional deficit. This was considered to be due to a number of factors, e.g., the dumping with regurgitation and vomiting, postsybal distress, and diarrhea. In addition to these, subnormal absorption through a loss of gastric reservoir, rapid intestinal transit, impaired pancreatic and biliary flow, imperfect mixing of digestive juices, and duodenal bypass were thought to be major contributing factors.

Anemia, folic-acid deficit, and post-gastrectomy bone disease were the most often encountered metabolic disturbances.

Williams suggests, as a prophylaxis for these nutritional deficits, medication containing iron salt, vitamin B12, folic acid, calcium, and vitamin D. Though this may represent some polypharmacy, such a tablet taken each night after gastrectomy should be safe, and might be expected to go a long way toward preventing deficiency states so commonly found in post-gastrectomy patients.

THE CHRONICALLY ISCHEMIC LOWER LIMB

The author succinctly summarizes the natural history, the diagnostic steps and the medical and surgical treatment of this disease. Careful history and examination localizes and grades the degree of ischemia.

Intermittent claudication will remain stable or improve over a five-year period in 60-90% of patients. In itself, intermittent claudication is not an indication for surgical intervention *unless* the individual cannot perform at a livelihood. Medical management must insist on abstinence from cigarettes, diligent and intelligent care of the skin of the feet and correction or treatment of other disease processes. Drugs have not proven beneficial for vasodilatation.

Ischemic rest pain, neuropathy or ischemic ulceration from slow arterial occlusion are indications for either reconstructive vascular surgery or

Continued

lumbar sympathectomy. The risk and postoperative prognosis of reconstructive surgery depend on the site of arterial occlusion. In general, the risk to life is higher, but the operative results are better for aortic-iliac disease than for femoral popliteal reconstruction. Autogenous vein grafts are favored for the latter. Lumbar sympathectomy is indicated if reconstruction is not feasible, but the results mainly affect the skin healing.

Comment: An excellent two-page summary which clearly defines the issues involved. It is a caution to the over-zealous surgeon, a comfort to the non-surgeon and an outline for those interested in patient welfare.

THE USE OF CORTICOSTEROIDS IN THE TREATMENT OF RESPIRATORY FAILURE ASSOCIATED WITH MASSIVE FAT EMBOLISM

It is estimated that fat embolism carries an overall mortality rate of 10-20 per cent. Typically, respiratory and neurologic symptoms appear two to three days after injury. Following an initial clear interval, signs of delirium, restlessness, and mild tachypnea are noticed. These symptoms and signs may clear spontaneously, but frequently, severe hypoxemia, respiratory and metabolic acidosis, coma, and death ensue. These patients die of respiratory failure.

The authors present the cases of three patients with fat embolism. One died and two recovered; the two patients who recovered had been treated with parenteral cortisone. In one, recovery occurred from a moribund state; in the other it was felt that cortisone prevented acute respiratory failure.

The etiology of fat embolism is poorly understood. The principal theories regarding the production of fat emboli are the mechanical theory proposed by Gauss and the biochemical theory advanced by Lehman and Moore. Perhaps the mechanical theory has the largest number of advocates, but recent studies seem to support the biochemical mode of action. Bergentz noted that platelet thrombi occur after injury and that fat emboli occur in conjunction with platelet emboli. As further evidence of this he noted a rise in red-cell mass triglycerides and a decrease in plasma triglycerides.

From the pathophysiologic standpoint, the lungs are the most common and important site of fat emboli. The chest roentgenogram frequently demonstrates diffuse fluffy infiltrates in both lung fields which may become manifest for the first time after an initial asymptomatic period of 24-72 hours. Arterial blood gases drawn at this time may show a decreased oxygen saturation associated with a decreased arterial carbon dioxide tension and a slightly elevated pH which is indicative of a mild diffusion block with hyperventilation in response to hypoxia. Compliance gradually decreases in those patients who exhibit progression of the pulmonary condition, and eventually in such cases cerebral and other organ involvement occurs. At autopsy the lungs are almost airless. There is marked capillary congestion and edema with areas of intra-alveolar hemorrhage and collapse alternating with zones of emphysema. Fat emboli ranging in size from 20-100 microns are found in arterioles and capillaries.

Treatment of fat embolism has been centered principally about efforts to combat respiratory failure. Heparin has been advocated; it is thought that by stimulating the release of lipoprotein lipase it might be of value in minimizing the initial embolization of fat. Its value may lie in its anti-inflammatory properties and ability to improve capillary blood flow. Low molecular weight dextran has been advocated as improving capillary blood flow by decreasing blood viscosity. Carbon dioxide inhalation has been used to increase cerebral blood flow, but high concentrations of oxygen and assisted respiration may afford greater benefit. Hypothermia may have some rationale by providing a decreased need for oxygen and its protective effect on the brain rather than any direct effect on respiratory failure.

The authors postulate that corticosteroids may be of value in the treatment of fat embolism by decreasing the permeability of cell membrane to toxic products, thereby inhibiting intracellular edema and cell destruction. Thus cortisone may inhibit the access of free fatty acids to the endothelial cell.

COMMENT: In both of the patients reported who were treated with cortisone, improvement was detected within a twelve-hour period. In one instance objective improvement was documented during that period by oxygen saturation studies. These responses are certainly impressive; but since the report deals with only two cases, these can serve only as preliminary, but nevertheless encouraging, observations. The patients reported seem to have been diagnosed as cases of fat embolism on clinical grounds. Although they exhibited rather classical clinical findings for such a diagnosis, it would have been of value to have obtained some substantiation from the laboratory standpoint.

THE EARLY DIAGNOSIS OF BREAST CANCER

It has been strongly indicated but not completely demonstrated that early diagnosis will lower the over-all death rate from this disease, which has not changed much in thirty years. The concept that the smaller or earlier the lesion is when diagnosed, the better the chance for cure has not been disproven. All methods of detecting a nodule that may indicate the presence of cancer are reviewed in the order of their clinical significance.

Radioactive isotopes. To date, their use has been disappointing.

Sonarography (Ultra-Sound). Several ultrasonic scanning systems have been devised. Data has been hard to interpret. At present it is in the development stage.

The thermograph is a heat-sensing apparatus which records a heat photograph of thermal changes over an area of inflammation or a malignant lesion. There are several other physiologic as well as pathologic conditions that also become evident even in normal breasts and preg-

Continued

nancy. Thermography is unavailable and still in the research stage.

Transillumination may aid in differentiation of cysts and solid tumors; however, it will not determine benign from malignant tumors. Its function is limited but may suggest the use of a needle aspiration for diagnostic material.

Cytology. Cancer cells found in a discharge from the nipple makes a positive diagnosis; but a negative finding does not rule out cancer. The same conclusion holds true of fluid aspirated from a breast cyst. Needle biopsy of a breast tumor may reveal no cancer cells but does not contraindicate biopsy. The conventional block removal of the tumor with serial sections is the most accurate procedure. One or two sections through a small breast tumor may be inadequate and miss completely an area of cancer cells.

Breast self-examination. Records indicate that 90% of breast cancer is detected by the patients themselves. The American Cancer Society highly recommends self-examination and teaching women how to do one. A film teaching the technique has been made available by the Society, and they recommend this worth-while examination after each menstrual period.

Mammography. This has been demonstrated as a well established diagnostic tool in the detection of breast cancer. At present a study to determine the value of periodic screening and clinical examination in reducing breast cancer mortality is under way.

The success of mammography depends on the excellence of the films and the experience and training of the radiologist.

Indications for mammography are listed:

1. Any patient with a lump in one or both breasts;
2. A check on the opposite breast in a patient with carcinoma in one breast;
3. Any patient with a discharge from the nipple;
4. Patients with a strong family history of breast cancer;
5. Patients with known breast dysplasias;
6. Patients with large breasts. To this may be added a routine internal check of the remaining breast after one mastectomy.
7. A high index of suspicion. A careful examination is the most available and important factor in the detection of breast cancer symptomatic or asymptomatic.

Discussion. This article published in Ca, a Journal published by the American Cancer Society, is comprehensive and timely. It rates the experimental as well as the established means for detecting cancer of the breast.

The importance of multiple sections through a tumor should be stressed. I can recall one instance where the block was reported negative but the patient developed a local recurrence one year later. Re-examination of more sections of the original block revealed cancer cells, missed in the previous sections. Also, a second instance in which the 20th section revealed malignancy. There is no substitute for routine examinations for breast cancer.

Botsford, Thomas W.: The Early Diagnosis of Breast Cancer. CA 16:4, 1966.

SIALOGRAPHY IN THE DIFFERENTIAL DIAGNOSIS OF PAROTID MASSES

The management of parotid tumors is hazardous and any diagnostic aid is welcome. Dr. Einstein presents his results from study of a consecutive series of 357 patients in whom he has used sialography as a diagnostic office procedure. Operation was performed on 265 patients; the remaining 92 patients were observed for a sufficient length of time to permit a satisfactory confirmation of the diagnosis.

Iodized oil in an amount of 0.5-1.5 cubic centimeters is injected through a blunt lacrimal duct needle using moderate pressure. Local anesthesia has been found to be unnecessary. Roentgenograms are then taken in stereoscopic posteroanterior and flat lateral views. The only untoward reaction noted has been a temporary swelling of the gland lasting a few hours.

The normal intact ductal system resembles a winter tree, with evenly distributed branches gently tapering off toward the periphery. Stensen's duct normally measures not more than 3 millimeters in diameter.

Pathologic findings can be classified as intrinsic space-occupying lesions, extrinsic indenting masses and abnormalities of the ductal system. Intrinsic space-occupying masses may produce rounded pressure defects in the major and lesser ducts. The ducts may be narrowed or stretched around the periphery of the mass, or the contrast material does not fill the branches in the area of the mass. Deep lobe masses show a rather characteristic medial ballooning, described as an umbrella effect. Extrinsic masses often cause indentation or rotation and displacement of the entire gland. Abnormalities of the ductal system are usually caused by inflammatory or neoplastic infiltrating processes. There may be variation in the caliber of the entire ductal system, with irregular interruption of the continuity of ducts, strictures, and sacculations.

The roentgenologic diagnosis proved correct in 96.6 per cent of the surgical patients studied.

COMMENT: It is apparent that this simple technique of sialography can contribute very useful and accurate information. Such a simple and safe procedure deserves wider application in the evaluation of lesions of the parotid gland.

Emoluments

Your chief ambition will be to deserve the confidence of society: your greatest happiness to extend and strengthen that confidence . . . you will make science the groundwork of your reputation; and acts of intelligence, honor and benevolence the material of the superstructure. You will thus become shining lights of the profession: you will sit down with the great ones of the earth: the learned will thirst after your conversation; the rich will contribute their homage, the poor will call you blessed, and your names will live and be held in honour.

Book Reviews

Education does not mean teaching people to know what they do not know; it means teaching them to behave as they do not behave. — Ruskin.

A CURRENT PEDIATRIC THERAPY — 1966-1967 — Edited by Sydney S. Gellis, M.D., and Benjamin Kagan, M.D. W. B. Saunders and Co., Philadelphia and London. January 11, 1966. Price $17.50. and

PEDIATRIC THERAPY — Edited by Harry C. Shirkey, C. V. Mosby Co., St. Louis, Missouri, 1966. $18.50.

These second editions of the two major hard-cover volumes on Pediatric Therapy attempt to provide a comprehensive account of therapies for diseases of infancy and childhood. Both books are well written and appear to succeed in their attempt. No single reviewer could attempt to question the quality and authority of the many experts who have contributed details of treatment of one or more of the diseases of children. Both books provide competent guidance to any physician who wants an expert's consultation on therapy for a problem on which he does not have current information.

The justification for a text of this type is that new drugs, antimicrobial agents, vaccines, etc. appear each year, with reports of their value so widely scattered through the literature that no individual physician is likely to be aware of them. Yet every doctor wants and welcomes medical guidance beyond the reports available from the pharmaceutical industry. In so far as Gellis' and Kagan's book is directed to this end, its purpose is obviously valid and desirable.

Since the second editions of CURRENT PEDIATRIC THERAPY and PEDIATRIC THERAPY have followed so close upon the first editions, it would appear that text books of this type are highly popular because of their currency and comprehensiveness, making available to the practitioner many details of treatment otherwise scattered throughout the literature. The validity of these approaches on a long-term basis is something that each individual must ascertain for himself. If he thinks that a text book of this type will be valuable to him, that is sufficient indication for purchase of either book. If he wishes an additional consultation on therapy, he might purchase both. CURRENT PEDIATRIC THERAPY has the edge in comprehensiveness, PEDIATRIC THERAPY in detail.

Warren J. Warwick, M.D.
Minneapolis, Minnesota

ENCYCLOPEDIA FOR MEDICAL ASSISTANTS — Louis Brachman, M.D., Cathedral Square, 448 pages, $14.95.

This book is as fascinating as it is instructive. It has some interesting facets for the physician as well as for his medical assistants. "Witch doctors dispense all medicines in powder form — and so they snip off a piece of dried-up snakeskin and grind it in a mortar with a stone pestle, adding a little powdered dragon's blood and the bitter-tasting root of a plant which produces great white blossoms when the moon is full, and finally some pulverized rhinoceros hide. The dark brown powder which results must be sniffed like snuff in order to drive away the evil spirits".

The book is well bound and the type is large enough for easy reading. The dictionary of medical terms and the index are adequate.

Carl O. Rice, M.D.
Minneapolis, Minnesota

SYMPOSIUM ON SURGERY OF THE OCULAR ADNEXA — New Orleans Academy of Ophthalmology, St. Louis. C. V. Mosby Company, 1966, 230 pages, Black and white illustrations, Chapter references, index, Price $16.00.

This book contains the presentations and "round table" discussion from the fourteenth annual meeting of the New Orleans Academy of Ophthalmology held in February 1965. As usual, the most noted contributors to the field of ophthalmic plastic and adnexal (excluding the eyeball itself) surgery were on hand. Their collected topics cover a good deal of the subject, forming a valuable reference and study volume for the ophthalmologist. Among the topics covered are: basic principles of plastic surgery; reconstructive surgery for burns of the lids; correction of ptosis (drooping lid); tumors of the lacrimal gland; surgery of the lacrimal drainage system; tumors of the lid, conjunctiva and orbit; and correction of entropian and ectropion (in and out turning respectively of the lid).

The Masonic Medical Research Laboratory

GORDON K. MOE, M.D., Ph.D.
Utica, New York

LOCATED ON the campus of the Masonic Home in Utica, New York, is a unique research institute, supported by the Masonic Fraternity of New York State and loosely affiliated with the State University's Upstate Medical Center in Syracuse and with other institutions of higher learning in the area. The Laboratory is the operating agency of the Masonic Foundation for Medical Research and Human Welfare, which was chartered as a non-profit corporation in 1947. The Foundation is governed by a board of nine distinguished business and professional leaders, prominent in civic, humanitarian, and Masonic affairs, under the leadership of President David R. Cunnison, of Bellerose, Long Island. After a period of seven years during which the Foundation granted close to $2,000,000 in support of research in rheumatic fever and related diseases, the Board of Directors elected to build, equip, and operate its own research facility. With the advice of a distinguished panel of medical advisors, including the original Director of Research, Dr. J. Murray Steele, a modern research laboratory was completed in the spring of 1958.

In 1957, Dr. Norman S. Olsen was appointed Assistant Director and given the responsibility for furnishing, equipping, and staffing the new laboratory and initiating its first research program in experimental atherosclerosis. Dr. Olsen received his Ph.D. in biochemistry from the University of Minnesota in 1942. In 1959, following the resignation of Dr. Steele, the author accepted appointment as Director of Research, sharing responsibility with Dr. Olsen and with Dr. Verner J. Wulff, formerly chairman of the Department of Zoology at Syracuse University. Within a few weeks after full-scale operation of the Laboratory began in 1960, Dr. Olsen and his family died in a fire at their home. Despite this tragic beginning, the Laboratory has steadily

Continued

grown to its present complement of twelve full-time professional scientists and 25 assistants.

Professional Staff

Gordon K. Moe, Ph.D. (Minnesota), M.D. (Harvard). Director of Research.

Verner J. Wulff, Ph.D. (Iowa). Associate Director of Research.

Mildred Behrens, Ph.D. (Syracuse). Research Scientist.

Lawrence Cerny, Ph.D. (Ghent). Established Investigator, American Heart Association.

Roderick Childers, M.D. (Dublin). Visiting Scientist, 1966.

Joseph Falzone, M.D., Ph.D. (Washington University). Senior Research Scientist.

Jaok Han, M.D. (Taegu), Ph.D. (S.U.N.Y.). Research Scientist.

Carlos Mendez, M.D. (Mexico). Senior Research Scientist.

John Merideth, M.D. (Kansas). U.S.P.H.S. Postdoctoral Fellow.

Harvey Samis, Ph.D. (Brown). Research Scientist.

William Stoller, Ph.D. (Syracuse). U.S.P.H.S. Postdoctoral Fellow.

Richard Tuttle, Ph.D. (S.U.N.Y.). Research Scientist.

Support of the Laboratory

Although the Laboratory has been assisted by grants from the National Institutes of Health, The American Heart Association and its Onondaga and Oneida County Chapters, the Life Insurance Medical Research Fund, the Atomic Energy Commission, the Upjohn Company, the Olsen Memorial Fund (to which many Minnesota friends have contributed) and various private donors, still the major support of our activities, more than 70%, comes from the voluntary contributions of the Masons of New York State through their annual Brotherhood Fund Campaign.

Academic Affiliations

The Laboratory maintains a loose but functionally effective relationship with Syracuse University, State University of New York Medical Center in Syracuse, and local colleges. Four graduate degrees have been granted by the Syracuse institutions on the basis of work conducted at the Laboratory, and members of the scientific staff hold academic appointments at Syracuse University, at the Medical College, and at Utica College of Syracuse University. Numerous research projects have been conducted in collaboration with investigators at these institutions.

The Research Program

The original and current research emphasis of the Laboratory is gerontology, defined in the broad sense as anything which happens after conception. Within this wide domain, some five major research programs are in progress at the present time.

1. *Nucleic acid metabolism as a function of age.* This program, under the direction of Dr. Wulff, has generated one of the most provocative hypotheses in the area of experimental gerontology. In 1961 it was observed that the metabolic turnover of ribonucleic acid (RNA) was significantly greater in the tissues of old rats than in young adults.[1-4] This surprising observation led to the postulate that aging and ultimate death of cells result from the gradual accumulation of errors in the nuclear DNA templates responsible for the synthesis of messenger RNA. Such errors (which might be designated "somatic mutations") could conceivably be cross-linkages between bases in twin strands of DNA, induced, for example, by ionizing radiation; but however they come about, the end result would be the synthesis of faulty or totally inappropriate messenger RNA. This deficiency would be reflected in a comparable deficiency of the enzyme molecules whose synthesis is directed by messenger RNA. So long as functional sites for the nuclear synthesis of RNA exist, the deficiency can be at least partially compensated by an increase in the rate of synthesis (i.e., an increased rate of turnover of RNA) ; but when adequate supplies of effective messenger RNA can no longer be produced, the cell must die.

The "error hypothesis" has survived many crucial tests but cannot be considered as proved. Assuming that errors do occur, and that they occur randomly, it is obvious that one cell may become deficient in enzyme "X", while its neighbor is inadequately supplied with enzyme "Y". In the tissue as a whole, no *single* enzyme may be lacking, but an individual cell may fail to survive the accumulated damage to its own synthetic machinery.

These investigations, which describe a major biochemical difference between the tissues of young and old animals, engage the full time attention of Drs. Samis, Falzone, and Stoller in addition to Dr. Wulff.

2. *Vasomotor regulation.* In 1960 Dr. Tuttle began a series of studies to define the integration of hemodynamic reflexes at the medullary and spinal cord level in the cat. In the course of these investigations he discovered a medullary site at which a brief period of moderate stimulation induced a delayed but profound hypotensive response, often leading to irreversible circulatory failure.[5] We are accustomed to look upon blood pressure regulation as the integration of cholinergic and adrenergic effector mechanisms, but neither activation of cholinergic, nor suppression of adrenergic systems should be expected to lead to a lethal outcome. Further study demonstrated that histamine liberation was also involved in the expression of the hypotensive response.[6] This observation led in turn to an investigation of the possible role of histamine in the operation of less drastic vasomotor regulations. It now appears certain that histamine is liberated at sites which directly affect vascular resistance in response to such physiologically benign stimuli as elevation of carotid sinus pressure. Histamine, so often invoked to explain pathological phenomena, now emerges as one of a family of functional mediators of normal vasomotor regulation.

3. *Rheology of blood.* Because of its non-Newtonian properties, blood has long distressed biophysicists. Its behavior in small tubes departs from the simple viscosity characteristics defined long ago by Poiseuille. When one wishes to describe in an all-inclusive equation the relation between pressure and flow of blood in tubes rigid or elastic, cylindrical or tapered, large or small, and at rates steady or pulsatile, the complications compound themselves. Yet this is the objective of Dr. Cerny. Dr. Cerný, who spent a fellowship year at the University of Minnesota with the late Dr. Cyrus Barnum

The Masonic Medical Research Laboratory at the time of its completion in 1958.

Continued

in 1958-59, has come close to defining a general flow equation for blood, and also for some of the macromolecular substances proposed as plasma substitutes.[7]

The importance of Dr. Cerny's studies becomes obvious when one considers the characteristics of the "ideal" plasma substitute. It must of course be non-toxic. It should develop an oncotic pressure comparable to that of normal plasma proteins and be retained within the blood stream; it should not be rapidly metabolized or excreted; nor should it be too viscous at effective concentrations in blood. Clearly, it is important to understand the viscous properties of such a substance, especially when mixed with blood, and particularly when flowing in tubes of capillary size. A substance with the characteristics of a fluid in the aorta and those of a gel in the capillaries could hardly serve a useful function.

4. *Cardiac impulse generation and transmission.* An understanding of the genesis and maintenance of cardiac arrhythmias should provide the necessary background for specific prophylaxis and therapy. One of the major efforts of the Laboratory has been the development and analysis of experimental models of clinically important arrhythmias: atrial flutter and fibrillation; idioventricular rhythms; ventricular fibrillation; A-V nodal reciprocal rhythms; functional heart block; "concealed" A-V conduction.

Dr. Mendez has succeeded in demonstrating, in *in-vitro* preparations of the rabbit A-V nodal region, the functional and morphologic basis of A-V reciprocation (atrial and ventricular "echoes"; A-V nodal tachycardia). Two propagation pathways were found within the atrial margin of the node. The refractory periods of these pathways differ enough to permit an impulse to enter one route at a time when the other is still incapable of impulse transmission, whereupon a return route for an echo becomes available. Repetition of the event can, under appropriate circumstances, lead to a self-sustained circus movement tachycardia.[8]

In a comprehensive study of the role of inhomogeneity in the genesis of self-sustained cardiac rhythms, it has been suggested that dispersion of the recovery times of neighboring elements may provide the adequate substrate for reentrant activity. The postulate was shown to be a feasible mechanism for atrial fibrillation in a computer model,[9] and Dr. Han has shown that agencies which increase dispersion also favor the development of spontaneous rhythms.[10] Recent observations in experimental animals, conducted by Dr. Han, provide an explanation for the greater incidence of ectopic ventricular activity at slow heart rates.

Collaborating in these studies at the present time are Dr. Childers, on leave from the University of Chicago, and Dr. Merideth, on leave from the Mayo Clinic as a candidate for the Ph.D. degree in the Mayo Graduate School of Medicine.

5. *Photoreception in the horseshoe crab.* Many visual physiologists make use of this ancient creature because of the simplicity of the photoreceptive units in its multi-faceted lateral eye. Dr. Behrens set out to demonstrate which of the cell types in the visual unit served as sense receptors and which as neural elements, and how the photic stimulus is transduced to nerve impulses. By means of intracellular microelectrodes, she has recorded the response to light of one of the receptor cells (the retinula cells) simultaneously with the response of the neural element (eccentric cell) of the same facet. Beyond that, she has also managed to stain each of the cells by the electrophoretic injection of different dyes, so that electrical responses could be clearly identified with cell types.[11] Recently, she has recorded the effects of destruction of single sense cells on the behavior of the visual receptor.

History of Medicine

A Brief History of the State University of New York Upstate Medical Center

MEDICAL EDUCATION in the United States goes back only for the short period of 200 years to the founding of the first school at the University of Pennsylvania in 1764. In the ensuing 100 years medical education passed through many phases and weathered many such storms as quack theories of practice; dissension among faculties as to what should be taught and how; who was authorized to grant degrees; and where did one obtain the bodies needed for dissection.

Medical education in New York State began in 1767 with the establishment of the Medical Faculty of King's College (later Columbia). The faculty of this school was distinguished and consisted of strong-minded individuals who did not always see eye to eye. In 1826 the faculty split, and the dissident group, led by David Hosack, formed the Rutger's College Medical Department, located in New York City. Since Rutgers was a New Jersey institution (formerly called Queen's College as the counterpart to Columbia), it was confronted with a legal action which held that New York State's rights were infringed under this arrangement. It was therefore necessary to find a New York school which could grant the necessary degree, and Geneva College (later Hobart and William Smith Colleges), which had the power to confer collegiate degrees and diplomas of any sort whatever, was willing to do this. One suspects, however, that part of its motivation was a desire to compete with its rival upstate institution, the College of Physicians and Surgeons of the Western District at Fairfield.

The new arrangement continued but a short time, for the College of Physicians and Surgeons at Columbia, fearing that a new school would mean the demise of the older, took the case to the State Supreme Court which declared the absentee granting of degrees illegal. The Rutgers Medical Faculty thus ceased to exist after four years of operation, during which time it had produced 104 graduates.

Geneva College then organized its own medical institution (Figure 3) which was founded in 1834 and began classes in 1835. The Geneva Medical institution prospered for some time; indeed, its success caused the school at Fairfield to close its doors in 1840. At that time three members of the Fairfield faculty joined Geneva, while others went on to the newly formed Albany Medical College.

In the late 1840s the Geneva Medical College received an application which was to precipitate on the school both fame and opprobrium. Elizabeth Blackwell (Figures 1 and 2) had applied to, and been rejected by, 13 of the country's 36 medical schools when she turned to Geneva. The faculty was either unable or unwilling to reach a decision on the matter and it was referred to the student body. The students, not entirely sure that the application was not a jest being perpetrated on them by a rival school, unanimously voted their approval. Miss Blackwell received a copy of their resolution and wrote that "the following unique and manly letter, . . . I had afterwards copied on parchment and esteem one of my most valued possessions."

Continued

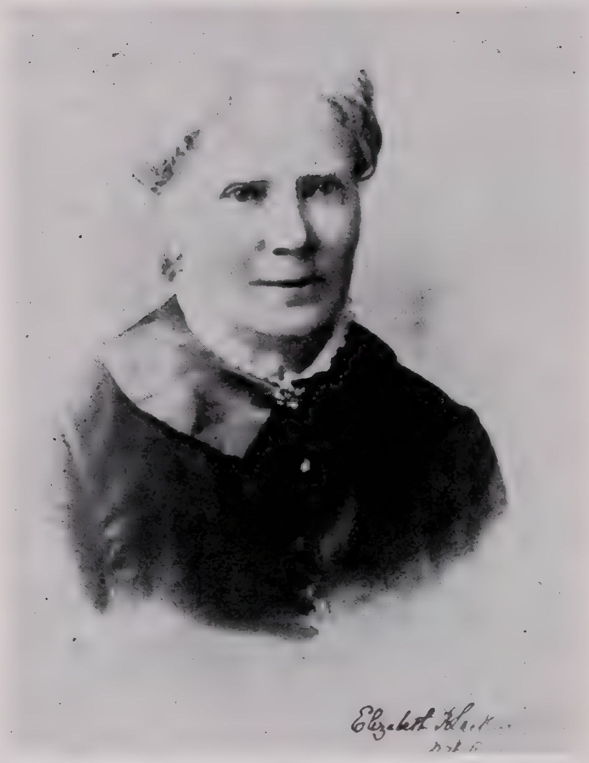

Fig. 1 — Photograph of Dr. Elizabeth Blackwell. She was the first woman to receive the M.D. degree from an American medical school.

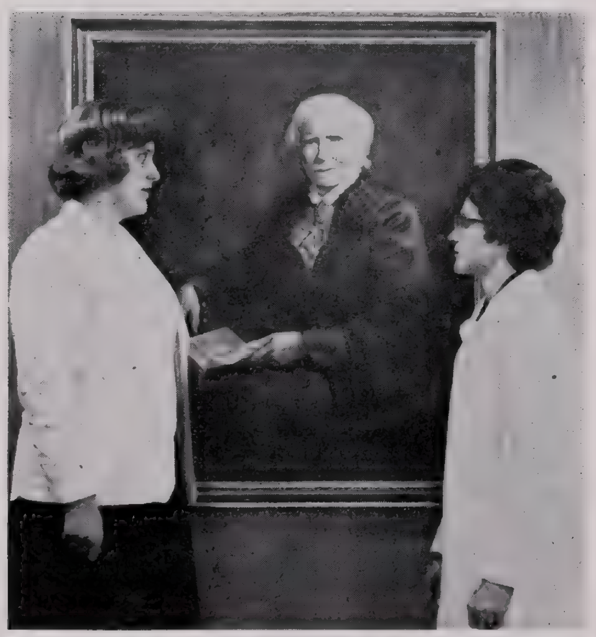

Fig. 2 — Portrait of Dr. Elizabeth Blackwell presented to the Upstate Medical Center in 1964 by the Women's Medical Sorority of the Upstate Medical Center. Dedication was made to perpetuate the memory of Dr. Blackwell. Dr. Patricia Numann (left), President of the Women's Medical Sorority and Dr. Mary Voorhess made the presentation.

At a meeting of the entire medical class of Geneva Medical College, held this day, October 20, 1847, the following resolutions were unanimously adopted:

> 1. Resolved — That one of the radical principles of a Republican Government is the universal education of both sexes; that to every branch of scientific education the door should be open equally to all; that the application of Elizabeth Blackwell to become a member of our class meets our entire approbation; and in extending our unanimous invitation we pledge ourselves that no conduct of ours shall cause her to regret her attendance at this institution.
>
> 2. Resolved — That a copy of these proceedings be signed by the chairman and transmitted to Elizabeth Blackwell.
>
> T. J. Stratton, Chairman.

Accordingly, she departed from Philadelphia on November 4, and, after a two-day journey reached Geneva at 11:00 p.m. on November 6, 1847.

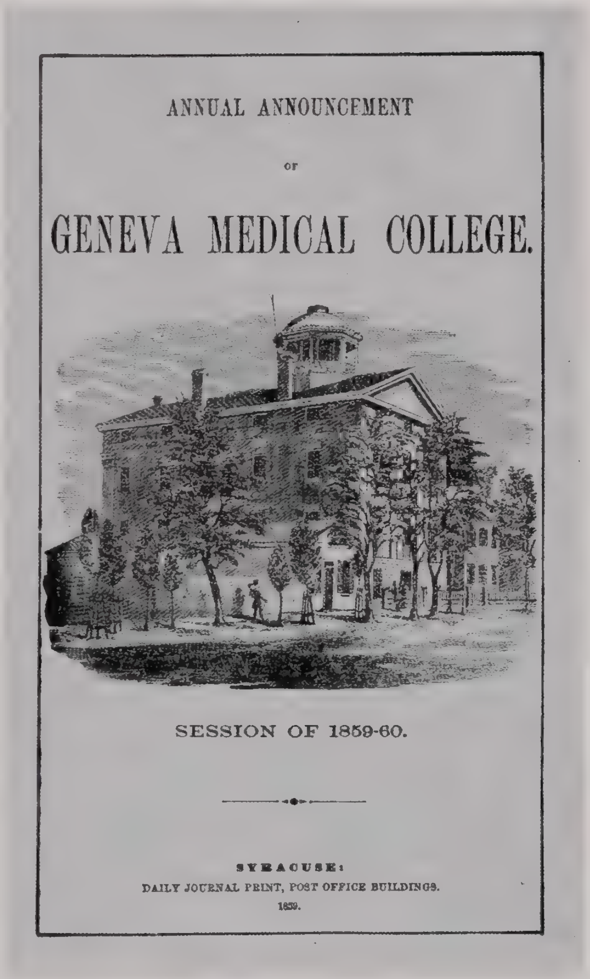
Thus it was that Geneva earned the distinction of being the first school in the United States to award the M.D. degree to a woman. After completing the required course of two sets of identical lectures, the normal mode of medical education of the day, Elizabeth Blackwell was graduated.

The public commencement of Elizabeth Blackwell's class took place on January 23, 1849. The valedictory address was given by Dr. Charles Alfred Lee, Professor of General Pathology and Materia Medica, and consisted in the main of a recapitulation of the ethics of the profession. Perhaps more unusual is the section which he devotes to a discussion of medical charlatans. Explaining that society consists of three classes, the medical skeptic, the overly credulous and superstitious, and those who view medicine "as one of the main pillars on which the welfare and happiness of society rests," he enumerates the current fads and theories and urges the student not to lose his interest in medical education. He is overly optimistic when he states that future humbugs will have but a sandy foundation due to the fact that "public credulity has been stretched until it has nearly snapped in twain," for the quack is not yet vanquished and a great deal more sophisticated.

In regard to the singular fact that a woman was being graduated for the first time he made the following comments:

"An event connected with the proceedings of this day deserves some notice on this occasion, calculated as it is to excite curiosity and comment, and to be held up as an example for other institutions to imitate or condemn. I mean the conferring of the degree of M.D. upon one of that sex which is generally supposed to be wanting in the physical, if not moral, qualifications necessary for the successful practice of the Healing Art. So far as I am informed, this is the first instance, in this country, or any other, where a female has graduated in medicine after having gone through the regular prescribed course and term of study; and in the present instance it is my duty to add, without the omission or the slighting of any branch of study, and that too in so thorough a manner as to leave nothing unattempted or unattained which it is necessary for one to know who expects to practice with honor and success in every department of the profession.

"Such an instance of self-sacrificing devotion to science; of perseverance under difficulties, and obstacles next to insurmountable — of unremitting, unrelaxing toil, in pursuit of that knowledge, so important to, and yet so rarely possessed by her sex — and all this for the purpose of mitigating human misery, relieving the sick, and extending her sphere of usefulness in the world — this, I say, deserves, as it will receive, the heartfelt approbation of every generous and humane mind. This event will stand forth hereafter as a memorable example of what woman can undertake and accomplish, too, when stimulated by the love of science and a noble spirit of philanthropy. Why should medical science be monopolized by us alone? Why should woman be prohibited from fulfilling her mission as a ministering angel to the sick, furnished not only with the softer and kindlier attributes of her sex, but with all the appliances and resources of science? If she feels called to this life of toil and responsibility, and gives evidence of her qualifications for such a calling, in humanity's name, let her take her rank among the disciples of Aesculapius and be



ANNUAL ANNOUNCEMENT

OF

GENEVA MEDICAL COLLEGE.

SESSION OF 1859-60.

SYRACUSE:
DAILY JOURNAL PRINT, POST OFFICE BUILDINGS.
1859.

Fig. 3 — Announcement of Geneva Medical College appearing in 1859.

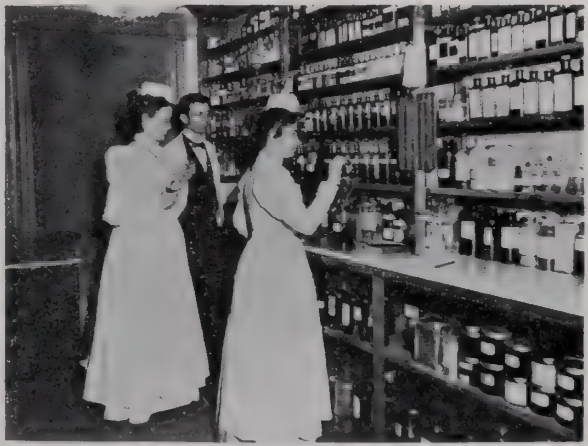


Fig. 4 — Syracuse Free Dispensary, 1899.

honored for her self-sacrificing choice. Such cases must ever be too few to disturb the existing relations of society, or excite any other feeling on our part than admiration at the heroism displayed and sympathy for the sufferings voluntarily assumed! God speed her, then, in her errand of mercy and crown her efforts with abundant success!"

The event was so notable that even *Punch* could not refrain from pointing out the moral lesson to its readers and published the following note and verse:

AN M.D. IN A GOWN

The MEDICAL TIMES *of the 21st ult. contains a full, true, and particular account of the admission of a young lady, Miss Elizabeth Blackwell, by the General [Geneva] Medical College, in the State of New York, to a physician's degree. Miss Blackwell had duly attended Lectures at the College, and received a formal diploma, under the title of "Domina," which was the only feminine that the Senate could find for Doctor.* PUNCH *really thinks this is a case for a copy of verses, which he accordingly subjoins, in honour of the fair M.D.*

Not always is the warrior male,
  Nor masculine the sailor;
We all know ZARAGOSSA'S tale,
  We've all heard "Billy Taylor."
But far a nobler heroine, she
  Who won the palm of knowledge,
And took a Medical Degree,
  By study at her College.

They talk about the gentler sex
  Mankind in sickness tending,
And o'er the patient's couch their necks
  Solicitously bending;
But what avails solicitude
  In fever or in phthisic
If lovely woman's not imbued
  With one idea of physic?

Young ladies all, of every clime,
  Especially of Britain,
Who wholly occupy your time
  In novels or in knitting,
Whose highest skill is but to play,
  Sing, dance, or French to clack well,
Reflect on the example, pray,
  Of excellent MISS BLACKWELL!

Think, if you had a brother ill,
  A husband, or a lover,
And could prescribe the draught or pill
  Whereby he might recover;
How much more useful this would be,
  Oh, sister, wife, or daughter!
Than merely handing him beef-tea,
  Gruel, or toast-and-water.

Ye bachelors about to wed
  In youth's unthinking hey-day,
Who look upon a furnish'd head
  As horrid for a lady,
Who'd call a female doctor "blue";
  You'd spare your sneers, I rather
Think, my young fellows, if you knew
  What physic costs a father!

How much more blest were married life
  To men of small condition,
If every one could have his wife
  For family physician;
His nursery kept from ailments free,
  By proper regulation,
And for advice his only fee
  A thankful salutation.

For DOCTRIX BLACKWELL — that's the way
  To dub in rightful gender —
In her profession, ever may
  Prosperity attend her!
"Punch" a gold-handled parasol
  Suggests for presentation
To one so well deserving all
  Esteem and admiration.*

The faculty was perhaps a little surprised at its liberality, nonetheless, for two years

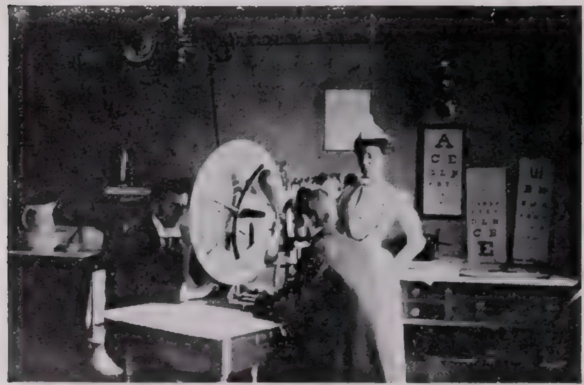

Fig. 5 — Eye room, Syracuse Free Dispensary, 1897-1904.

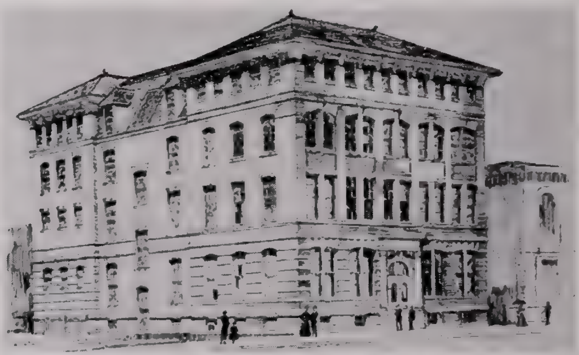

Fig. 6 — Syracuse University Medical College Building, opened in 1896.

---

*Punch 16:226, 1849.

later, when Elizabeth's sister Emily applied for admission, she was denied, and after much difficulty was finally admitted to Western Reserve.

Elizabeth Blackwell went on to become a most distinguished alumna of the school. In 1857, together with her sister, she established the New York Infirmary, the first such institution of its kind devoted to women. Later she was instrumental in forming the Nursing Corps for the Union Army during the Civil War (she was not accepted as an equal by the Army physicians).

She ended her life in England still fighting for the rights of women and numbered among her friends the redoubtable Florence Nightingale. Her long and useful career ended in 1910 at the age of 89.

The College reached its zenith in the 1840s. In 1843, 195 students were enrolled, the largest number recorded, and in 1846, 49 candidates received degrees. The number of students began to decline in the 1850s, and in 1854 there were no graduates because the course of lectures was interrupted. The Civil War years did not appreciably affect the number of students, but there was a brief resurgence in the number of graduates in 1866, 1867, and 1868.

The decline was partly due to the establishment of the medical department of the University of Buffalo, which drew students and faculty away from Geneva. The difficulties presented by the smallness of the town caused the faculty to investigate an alliance with the newly organized university at Syracuse, which also had the advantage of providing two new hospitals there for clinical work.

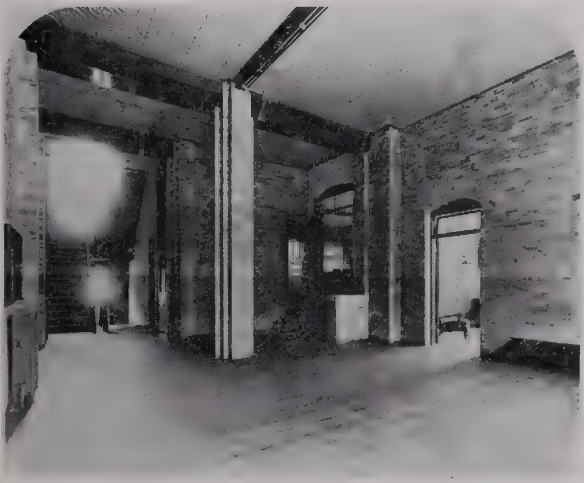

Fig. 7 — First floor of Syracuse University Medical College, 1896.

Bringing the library and anatomical museum with them, members of the faculty moved to Syracuse in 1872 and began the first session as the medical department of Syracuse University in October of that year. All told, some 849 doctors had been graduated from the Geneva campus.

The Medical Department of Syracuse University pioneered in many reforms in medical education and as early as 1875 had adopted the three-year graded course system following the lead of the Chicago Medical College which had begun the program in 1859 and Harvard which started it in 1871. The medical school was the first in the country to install and equip a physiological laboratory (Figure 8) for students, an innovation begun when it opened a new building (Figures 6 and 7) in 1896. An interesting feature was the pulley system, connected to a central power source, used to drive all kymographs at a standard speed.

The State University of New York was organized in 1948. It first purchased the Long Island College of Medicine in Brooklyn, which became the Downstate Medical Center, and then in 1950 purchased the

Continued

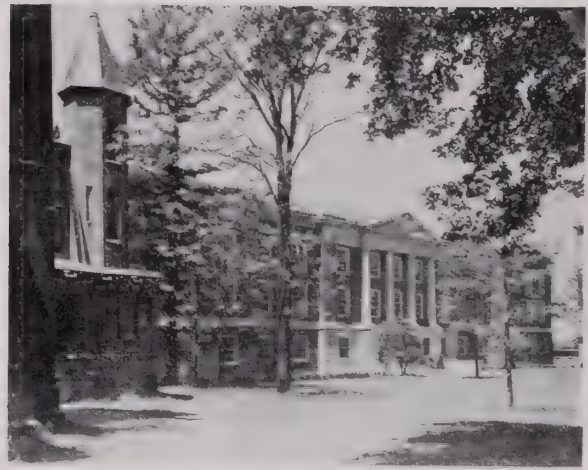

Fig. 9 — Syracuse University Medical School, 1937-1958. Yates Castle is on the left.

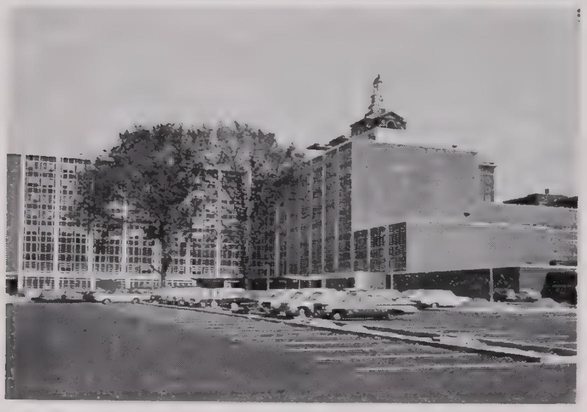

Fig. 10 — New State University Hospital, opened for service in July, 1965.

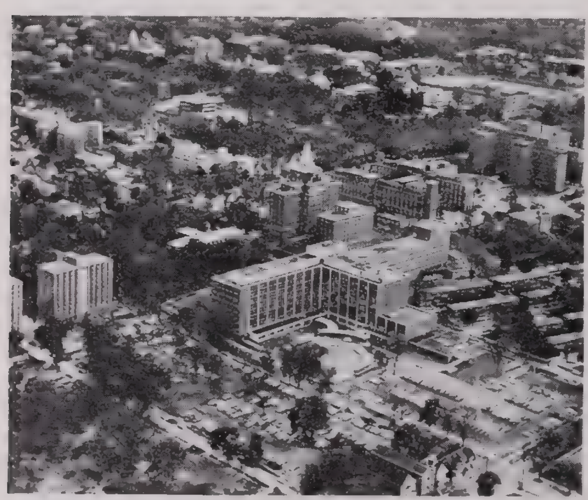

Fig. 11 — Present Upstate Medical Center Complex. The new State University Hospital is in the foreground. The U. S. Veterans Administration Hospital is to the far right of the picture. The building with the tower is Memorial Hospital with the administration and basic science building to its right and Crouse-Irving Hospital behind.

College of Medicine (Figure 9) and the School of Public Health Nursing from Syracuse University, as the nucleus of the Upstate Medical Center. It is ironic that the third State University Medical Center should be the school at Buffalo which was so influential in the decline of the Geneva Medical College. Buffalo joined the State system in 1960.

The medical school at the Upstate Medical Center was reorganized during the 1950s, the curriculum enlarged and a new wing added to the Basic Science Building, three floors of which now house the medical library, with its original collection from the Geneva Medical College.

In 1961 ground was broken for the new Hospital (Figure 10), within a few hundred feet of the Basic Science Building. The Hospital's three wings house expanded research facilities, a 375-bed hospital, and the outpatient services of the Center, and were opened for service in July 1965.

Twin residences, situated on Elizabeth Blackwell Street to the north of the Hospital, house some 540 of the Medical Center's students and staff.

The next construction phase consisting of a student activities building which will be located between the two residence units is now in progress. Also included in the current expansion is the construction of a computing facility which will bring together and house four major activities: the State University of New York Computerized Biomedical Information Network, the research data processing center for the entire Medical Center, the administrative data processing facility, and the patient data storage and retrieval center. Completion of this program is expected in 1968.

The Hospital of the Good Shepherd

The new State University Hospital is the successor of the House of the Good Shepherd which was founded in 1872 as the teaching unit of the new College of Medicine. Housed in frame buildings until 1901, it was replaced by the still existing structure, then one of the most modern hospitals in the country. It featured self-service automatic elevators, centralized ventilation systems which allowed the air to be changed in each ward every eight minutes, and was completely wired for electricity and telephone.

In the early 1880s women took their place as nurses in the Hospital. They were untrained and received what instruction they could from the physicians and from each other. In 1885 the Hospital established a school for nurses' training and accepted a class of six for a two-year course. The first group graduated in 1887, as did a class at Johns Hopkins Hospital, the first such schools in the country to offer nursing education.

The Hospital of the Good Shepherd did not officially become a part of the Syracuse University until 1915, when the shift to University auspices was necesitated by the need for financial support and assistance. At that time its School of Nursing was also incorporated into the University structure where it remains one of the professional schools, giving both B.S. and M.S. degrees. The Upstate Medical Center Library provides the instructional resources for this program's clinical portions, and practical training is undertaken in the new Hospital.

The Syracuse Free Dispensary

Originally founded in 1888 by a group of local businessmen and physicians under the leadership of Dr. John Van Duyn, the Dispensary (Figures 4 and 5) continued the work begun by Dr. Van Duyn and other private physicians. In the first 30 years it treated some 51,000 patients at a cost to each of approximately ten cents per prescription. By 1966 the Dispensary was treating some 80,000 patients a year.

There have been four homes for the institution prior to its move into the State University Hospital, each reflecting the increasing importance of the institution to the community. In 1917 the Dispensary began its formal association with the College of Medicine in new quarters built by the University, and since 1950 it has served as the Upstate Medical Center's outpatient department.

The objectives of the Dispensary were stated in the articles of incorporation on July 17, 1888, and were "the providing and furnishing medical and surgical aid to such persons as may be in need thereof and unable by reason of poverty to procure the same: the more successful treatment and control of disease and the advancement of medical science."

The hopes of Dr. Herman G. Weiskotten, Dean of the School from 1922 to 1951, that the Dispensary would some day be housed in a wing of the Medical School have been realized and, as Dr. Alphonse M. Schwitalla said at the 50th Anniversary ceremonies in 1938, this arrangement will "lay the foundation for a greater and more efficient and better out-patient department."

"Let Each Become All He is Capable of Being"

The educational program has grown to include the College of Medicine, a two-year School of Nursing granting an Associate in Applied Science degree (since 1959), graduate programs in the medical sciences leading to M.S. or Ph.D. degrees, and extensive Intern-Resident programs. The Medical Center's College of Allied Health Professions opened in the fall of 1965 with the first class of the School of X-ray Technology, a two-year program leading to an Associate in Applied Science degree, and the first class in the Medical Technology program. Students enter this program after completing two years of college, and after two years at the Medical Center receive a B.S. degree. In 1967 a Nursing program leading to a B.S. degree is planned. Other schools in the supportive medical sciences are also planned.

The Medical Center (Figure 11) is a complex of affiliated hospitals which can accommodate over 1800 patients. Currently, affiliations are maintained with City Hospital; Syracuse Memorial Hospital; Community-General Hospital; St. Mary's Hospital; City Health Department Bureau of Maternal and Child Care; Crouse-Irving Hospital; Syracuse Psychiatric Hospital; the U. S. Veterans Administration; St. Joseph's Hospital; and the State University Hospital. Within the next ten years the size of the Medical

Continued

Center complex will expand to accommodate more than 3,000 patients, as a new short-term mental hospital, additional floors for the State University Hospital, and a new and expanded Crouse-Irving Hospital are constructed.

Green Medicinals

Herbs for the Lungs

Ecclesiasticus said: The Lord hath created medicines out of the earth and a wise man will not abhor them. Among the herbal remedies for lungs are angelica, borage, forget-me-not, hyssop, mullein, primrose, sundew, vipers bugloss, and wild cherry.

For a tonic using borage one can drink:

Borage in a Cool Tankard

A quart of mild ale, a glass of white wine, one of brandy, one of capillaire, the juice of a lemon, the peel pared thin, nutmeg grated on top, a sprig of borage, a bit of toasted bread and a few of the blue flowers floating on top. — Dr. Kitchener (1823)

Specialists

It has been only a few years since the old-time general practitioner was everywhere. Just look around you and see now how the system has changed! If your liver begins to misconduct itself the first thought of the modern operator is to cut it out and hide it some place where you can't find it. The old-timer would have bombarded it with a large brunette pill about the size and color of a damson plum.

Except in the country the old-time, catch-as-catch-can general practitioner appears to be dying out. Hence the expert who treats you for just one particular thing. With a pain in your chest, say, you go to a chest specialist. So long as he can keep the trouble confined to your chest, all well and good. If it slips down or slides up he tries to coax it back to the reservation. If it refuses to do so, he bids it an affectionate adieu, makes a dotted mark on you to show where he left off, collects his bill and regretfully turns you over to a stomach specialist or a throat specialist, depending on the direction in which the trouble was headed when last seen.

— Irvin S. Cobb: Speaking of Operations

Medical Men on Postage Stamps

Aesculapius, Thessalonian physician immortalized as the god of medicine, has been commemorated on a postage stamp by two countries: Romania in 1932 and Spain in 1948.

Agostini Bassi (1773-1856), microbiologist and precursor of Pasteur and Koch, advocate of the germ theory of disease, and author of works on pellagra and cholera, was honored on an Italian postage stamp in 1953.

Medical Economics

Is Your Home a Sound Investment?

If someone were to tell you that the difference in cost between a $35,000 residence and a $70,000 residence can amount to $130,000 you would be inclined to think that he had completely lost his wits. However, it is true!

For the past several years we have noted an ever-increasing trend toward bigger, more costly homes — far too frequently at the expense of a sound over-all financial plan. Just how much "status symbolism" is involved in these ultra-expensive homes is not known; but it is immediately obvious that they involve some objective beyond adequate housing.

Too frequently the size of the investment in a residence is governed by the monthly mortgage payments. If the payment can be supported, the cost is often disregarded or considered inconsequential. Rarely does the prospective buyer measure the true and complete cost of a luxury-house in comparison to an adequate home.

In an effort to measure this cost, we recently studied the financial aspects of owning homes at various price levels. In the following example we have assumed that our client is in a 40% top tax bracket and is considering the purchase of one of three homes — one costing $35,000, one costing $50,000, and one costing $70,000. He has $15,000 cash for equity.

	House A	House B	House C
Total Cost	$35,000	$50,000	$70,000
Cash for Equity	15,000	15,000	15,000
Mortgage Balance	$20,000	$35,000	$55,000
Monthly Mortgage Payment (20 year, 6% mortgage)	$143.29	$250.76	$394.10

At this point, the Doctor feels he can support the $394.10 monthly payment but wonders what other factors may be involved:

Estimated Annual Difference	House B Over House A	House C Over House A
Annual Mortgage Payment	+ $1,300	+ $3,000
Additional Property Taxes	+ 400	+ 1,200
Additional Maintenance	+ 100	+ 500
Estimated Annual Difference — 20 Years	+ $1,800	+ $4,700

Here we discover that House B will require about $150 per month in cash outlay over House A; House C will require nearly $400 more per month. These differences do not even consider additional and more expensive furniture, additional domestic help and the inevitable increase in the over-all cost of living which accompanies the luxury home.

The Doctor is impressed at this point — but our comparison has only begun. What would this monthly difference amount to if invested wisely in a productive medium?

In House B, the cost differential was $1,800 per year; however, this includes interest and taxes which are deductible and result in tax savings. The after-tax difference is $1,425 per year. If this amount were invested to yield and appreciate at 6%, the net after-tax performance would be about 3½% and this would accumulate to $43,500 over the twenty-year mortgage period.

In House C, the cost differential was $4,700 before tax, or $3,700 after tax. This invested under the same circumstances as previously stated would grow to $100,000 over the twenty-year period.

Continued

If we were to make a very liberal assumption that these homes would retain their original cost differential, the loss from purchasing House B over House A would be $43,500 less $15,000, cost differential, or a net loss of $28,500. The loss on House C would be $104,000 less $35,000, cost differential, or a net loss of $69,000.

Extending the period of ownership from twenty years to thirty years would increase the net loss on House B to about $50,000 and the net loss on House C to about $130,000. These figures give dramatic emphasis to our contention that excessive expenditure on a residence can have permanent and serious results in terms of accomplishing a reasonable degree of financial security. These figures also point out the logic of measuring the long-term effect of an excessive residential commitment — as compared to the trend toward measuring the size of the commitment in terms of ability to meet the monthly mortgage payment.

While there are advocates of various "rules of thumb" for measuring the amount which should be invested in a home, we believe that this determination can be made on the basis of a study of the individual's specific financial circumstances. For example, a Doctor earning $30,000 might have debt and family circumstances which should limit his home cost to $25,000, while another earning $30,000, having just inherited $100,000, could reasonably spend $50,000.

In the absence of unusually favorable circumstances, such as sizeable inheritance or outstanding past investment success, or various adverse circumstances, such as bad health or heavy liabilities, the following guide is probably reasonable for the average Doctor.

Annual Income Before Taxes	Reasonable Value for Residence	Maximum Mortgage
$ 20,000	$25,000	$20,000
30,000	30,000	20,000
40,000	35,000	25,000
50,000	40,000	25,000
60,000	45,000	25,000
70,000	50,000	30,000
80,000	55,000	30,000
90,000	60,000	30,000
150,000	75,000	35,000

In addition to the value of the residence, the matter of maximum mortgage is quite important. The further you advance into luxury-type homes, the greater the ratio of equity to debt should be. This is based upon our philosophy of purchasing luxuries with previously accumulated funds rather than purchasing them with future earnings. Following this guide for total cost and maximum mortgage will also insure an adequate residue of funds for use in accumulating income-producing assets.

In summary, it has been our experience that over-commitment for a residence can cause more financial problems than any other single phase of your financial planning. In considering a residence purchase, all factors must be considered objectively and the final decision must be based upon financial logic rather than pure desire. Once a final decision has been made, you are going to have to live with it for many years.

MINNESOTA MEDICINE Cover Photographs

In order to encourage more physicians to submit color slides for use on the cover of MINNESOTA MEDICINE the competition is being discontinued. The picture editor now invites all physician-photographers to send 35 mm. color slides of suitable subjects for consideration as cover pictures. The format must be horizontal because of printing limitations. Pictures highlighting Minnesota seasons, places, and activities will have an automatic advantage. No limit as to the number of slides sent will be set, but all slides should be individually identified. All slides will be returned. Physicians whose pictures are used as covers will be recognized in MINNESOTA MEDICINE. We can use many more pictures than we have received in the past.

Meetings and Announcements

Appreciation, whether of nature, or books, or art, or men, depends very much on temperament. What is beauty or genius or greatness to one, is far from being so to another. — Tyrone Edwards

Ramsey County Medical Society — February 27, 15th floor, Lowry Medical Arts Bldg., St. Paul, 8:00 p.m.

Announcement

A combined meeting of the Minneapolis Surgical Society and the Hennepin County Medical Society will be held January 9 at the Pick-Nicollet Hotel, 6:00 p.m. Inaugural Theses: Eugene F. Bernstein, M.D. "Long Term Results in the Treatment of Abdominal Aortic Aneurysms"; Richard E. Larson, M.D. "Obstructive Lesions of the Superior Mesenteric Artery."

New drugs take exams, too.

Today, virtually every medical school in the United States cooperates with pharmaceutical manufacturers in the clinical evaluation of new and promising drugs. Just as you might find it significantly more difficult to practice medicine without the useful new compounds made available through original pharmaceutical research in the past twenty years—prescription-drug manufacturers would find it equally difficult to obtain extensive, long-term, dependable evaluations of new therapeutic agents without the close cooperation of medical staffs and clinical facilities of medical schools and teaching hospitals. Such cooperation leads toward more effective care of more patients—the common goal of medical and pharmaceutical research—toward reduction in the cost of disease, toward increase in useful longevity.

This message is brought to you as a courtesy of this publication on behalf of the producers of prescription drugs.

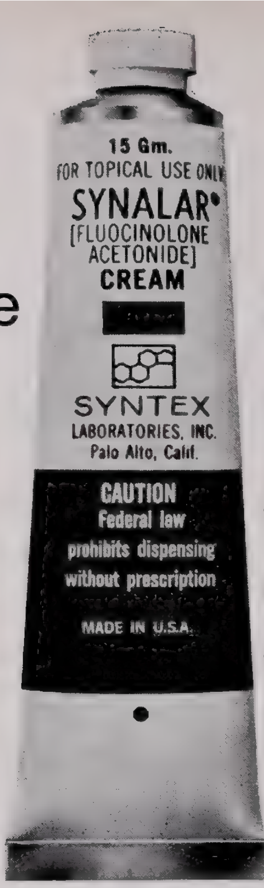
new small size



Synalar® 0.01%
(fluocinolone acetonide) **cream**
15 Gm.

for even greater economy in office or hospital practice

the superiority topical with the

Now you can prescribe as little or as much Synalar Cream 0.01% as is needed for a particular therapeutic problem in a size that permits the greatest economy for your patient. The new 15 Gm. tube, for example, is best suited for short-term therapy and for small sites. For more extensive body areas prescribe the 45 Gm. tube—a size that's also ideal for your treatment table. And the 120 Gm. jar is most economical for hospital use. Thus, with Synalar Cream 0.01%, you have the superiority of a modern topical corticosteroid shown to be more effective than 1% hydrocortisone[1-3] plus the economy that makes therapy practical for use in more dermatologic conditions, in long-term maintenance, with occlusive dressings in resistant cases, and in extensive area involvement.

Contraindications: Tuberculous, fungal, and most viral lesions of the skin (including herpes simplex, vaccinia, and varicella). Not for ophthalmic use. Contraindicated in individuals with a history of hypersensitivity to any of its components. **Precautions:** 1. *General*—Synalar Cream 0.01% is virtually nonsensitizing and nonirritating. Where severe local infection or systemic infection exists, the use of systemic antibiotics should be considered, based on susceptibility testing. While topical steroids have not been reported to have an adverse effect on pregnancy, the safety of their use on pregnant females has not absolutely been established. Therefore, they should not be used extensively on pregnant patients, in large amounts, or for prolonged periods of time. 2. *Occlusive dressing method*—With occlusion of extensive areas, systemic absorption of the corticosteroid may occur, and suitable precautions should be taken. Occasional patients may show contact sensitivity to a particular dressing material or adhesive. Miliaria, folliculitis, or pyodermas have been seen infrequently with the use of this technique. The development of infection requires appropriate antibacterial therapy and discontinuation of the occlusive dressing method. Local atrophy and striae have been reported with protracted occlusive dressing therapy. While lesion relapses can be expected to occur in many psoriatic patients, remissions may persist for several weeks to several months in favorable cases. The patient whose psoriasis is in an active stage, with recent appearance of new lesions, may not be a good candidate and may show early relapse. Some plastic films may be flammable, and due care should be exercised in their use. Similarly, caution should be employed when such films are used on or left near children to avoid the possibility of accidental suffocation. **Side Effects:** Side effects are not ordinarily encountered with topically applied corticosteroids. As with all drugs, however, a few patients may react unfavorably to Synalar under certain conditions. **References:** 1. Cahn, M. M., and Levy, E. J.: J New Drugs 1:262 (Nov.-Dec.) 1961. 2. Norinyl® tablets
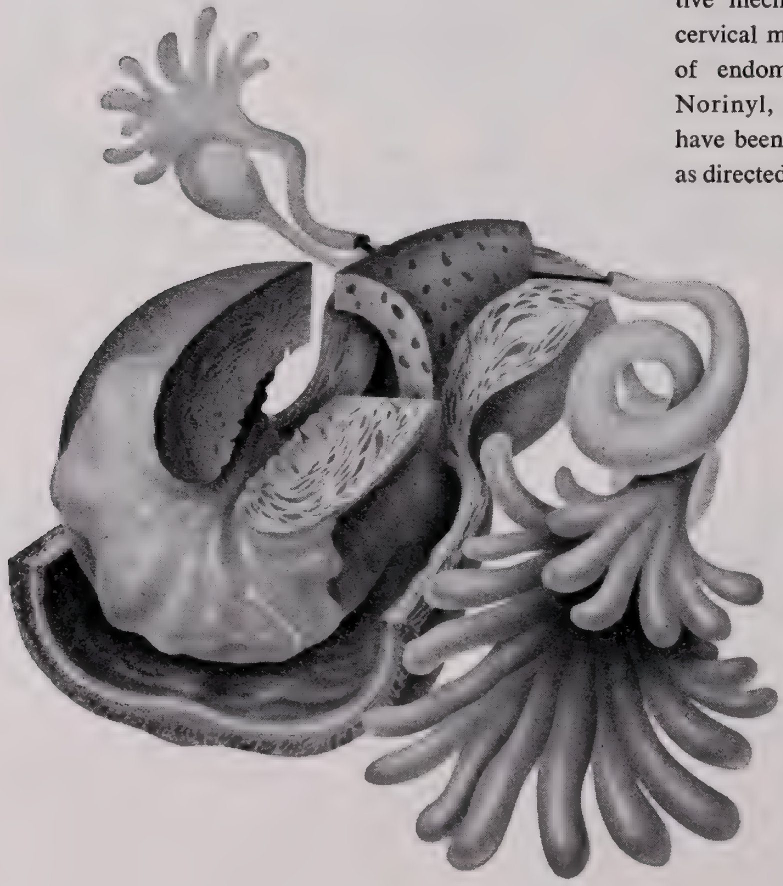
(norethindrone 2 mg. $\bar{c}$ mestranol 0.1 mg.)

for multiple contraceptive action that has produced a record of unexcelled effectiveness

inhibition of ovulation by means of 2 time-proved hormonal agents

production of a cervical mucus hostile to sperm motility and vitality

creation of an endometrium unreceptive to egg implantation



no unplanned pregnancies

Norinyl provides multiple action for maximum assurance of success. It does not depend on ovulation inhibition alone for contraceptive effectiveness. The mechanism of action of combined hormonal therapy results in ovulation inhibition reinforced by other protective mechanisms, including a hostile cervical mucus[1-13] and an acceleration of endometrial changes.[1-3,7-16] With Norinyl, no unplanned pregnancies have been reported to date when used as directed.

plus important supportive benefits that help her through those critical early months of oral contraception

low incidence of side effects

Low incidence of BTB and spotting, nausea and amenorrhea tends to minimize side effect problems and increases patient cooperation.

no confusion about dosage

An unbreakable "confusionproof" package makes it easy to adhere to prescribed dosage schedule: individually sealed tablets numbered from 1 through 20 *plus* monthly calendar record enables patient to double-check dosage intake by day and corresponding tablet number.

NORINYL
2
SYNTEX
T F S
2
1

Contraindications: Thrombophlebitis or pulmonary embolism (current or past). Existing evidence does not support a causal relationship between use of Norinyl and development of thromboembolism. While a study which was conducted does not resolve definitively the possible etiologic relationship between progestational agents and intravascular clotting, it tends to confirm the findings of the Ad Hoc Advisory Committee appointed by the Food and Drug Administration to review this possibility. Cardiac, renal or hepatic dysfunction. Carcinoma of the breast or genital tract. Patients with a history of psychic depression should be carefully studied and the drug discontinued if depression recurs to marked degree. Patients with a history of cerebral vascular accident.

Warning: Discontinue medication pending examination if there is sudden partial or complete loss of vision, or if there is a sudden onset of proptosis, diplopia or migraine. If examination reveals papilledema or retinal vascular lesions, medication should be withdrawn.

Precautions: By May 1963, experience with norethindrone 2 mg.—mestranol 0.1 mg. had extended over 24 months. Through miscalculation, omission or error in taking the recommended dosage of Norinyl, pregnancy may result. If regular menses fail to appear and treatment schedule has not been adhered to, or if patient misses two menstrual periods, possibility of pregnancy should be resolved before resuming Norinyl. If pregnancy is established, Norinyl should be discontinued during period of gestation since virilization of the female fetus has been reported with oral use of progestational agents or estrogen. When lactation is desired, withhold Norinyl until nursing needs are established. Existing uterine fibroids may increase in size. In metabolic or endocrine disorders, careful clinical preevaluation is indicated. A few patients without evidence of hyperthyroidism had elevated serum protein-bound iodine levels, which in the light of present knowledge, does not necessarily imply hyperthyroidism. Protein-bound iodine increased following estrogen administration. Bromsulphalein retention has occurred in up to 25% of patients without evidence of hepatic dysfunction. Studies from 24-hour urine collections have shown an increase in aldosterone and 17-ketosteroids and decrease in 17-hydroxycorticoid levels. Thus, Norinyl should be discontinued prior to and during thyroid, liver or adrenal function tests. Because progestational agents may cause fluid retention, conditions such as epilepsy, migraine and asthma require careful observation. Thus far no deleterious effect on pituitary, ovarian or adrenal function has been noted; however, long-range possible effect on these and other organs must await more prolonged observation. Norinyl should be used with caution in patients with bone, renal or any disease involving calcium or phosphorus metabolism.

Side Effects: Intermenstrual bleeding; amenorrhea; symptoms resembling early pregnancy, such as nausea, breast engorgement or enlargement, chloasma and minor degree of fluid retention (if these should occur and patient has not strictly adhered to medication plan, she should be tested for pregnancy); weight gain; subjective complaints such as headache, dizziness, nervousness, irritability; in a few patients libido was increased. In a total of 3,090 patients, 2.2% discontinued medication because of nausea.

NOTE: See sections on contraindications and precautions for possible side effects on other organ systems.

Dosage and Administration: One Norinyl tablet orally for 20 days, commencing on day 5 through and including day 24 of the menstrual cycle. (Day 1 is the first day of menstrual bleeding.)

Availability: Dispensers of 20 and 60 tablets; bottles of 100.

Norinyl® tablets
(norethindrone 2 mg c̄ mestranol 0.1 mg)

for multiple contraceptive action

against the usual gram-negative urinary pathogens

Why use five...where **one** will do?

In a recent 217-patient hospital study,[1] urinary tract infections were treated with a variety of widely prescribed antimicrobial agents including: a sulfonamide (40 patients), chloramphenicol (20 patients), nitrofurantoin (33 patients), nalidixic acid (30 patients), tetracycline (27 patients), colistimethate sodium (22 patients) . . . and 2 combinations of 5 agents each (45 patients). The 2 combinations were selected to afford maximal theoretical antibacterial coverage against the usual urinary pathogens. They were (1) tetracycline, chloramphenicol, nitrofurantoin, ristocetin and polymyxin B; and (2) tetracycline, chloramphenicol, erythromycin, nitrofurantoin and colistimethate sodium.

This clinical study shows that the two combinations of antibiotics were not superior to some of their single components. The authors point out that antibiotic antagonism often negates theoretical advantages of multiple therapy. Coly-Mycin Injectable (colistimethate sodium) was one of the single components that was shown to be equal to the combinations and eradicated bacteriuria in two-thirds of the patients.

Theoretical choice of multiple antibacterial therapy has been shown to be no more effective than one well-chosen agent which also offers least patient exposure to possible side reactions, toxicities, allergic manifestations and higher drug costs.

1. McCabe, W. R., and Jackson, G. G.: New England J. Med. 272:1037, 1965.

in gram-negative urinary tract infections often the single well-chosen agent

COLY-MYCIN
INJECTABLE

Coly-Mycin® Injectable

(colistimethate sodium)

Indications: Especially indicated for the treatment of severe acute and resistant chronic urinary tract infections due to sensitive strains of gram-negative organisms. Also indicated in respiratory tract, surgical, wound and burn infections and in septicemia due to sensitive organisms. Particularly indicated when any of these infections are caused by sensitive strains of *Pseudomonas aeruginosa.*

Adverse Reactions: Occasional reactions such as circumoral paresthesias, tingling of the extremities, pruritus, vertigo or dizziness may occur. Reduction of dosage may alleviate symptoms. Therapy need not be discontinued, but such patients should be observed with extra care.

Warning: Patients should be cautioned not to drive vehicles or use hazardous machinery while on therapy.

Precautions: In cases of impaired or suspected renal impairment, use with greater caution and reduce dosage in proportion to extent of impairment. Transient elevations of BUN have been reported. As a routine precaution, appropriate blood studies should, therefore, be made during prolonged therapy.

As with all polypeptides, the possibility of muscular weakness, including apnea, due to inadvertent overdosage or normal dosage in the presence of impaired renal function, should not be overlooked. In cases of apnea, medication should be promptly discontinued and assisted respiration given until serum levels fall and normal breathing is restored.

Other antibiotics, such as kanamycin, streptomycin, dihydrostreptomycin, polymyxin, and neomycin, may also have varying neurotoxic or nephrotoxic potential. They should be used with great caution concomitantly with Coly-Mycin Injectable (colistimethate sodium).

For deep intramuscular injection only.

Dosage: By the I.M. route only, in 2 to 4 divided doses ranging from 1.5 to 5 mg./Kg./day (0.7 mg. to 2.3 mg./lb./day). Average adult dose is 2.5 mg./Kg./day (1.1 mg./lb./day). In the presence of bacteremia, septicemia, or other serious infection, greater than average doses may be required; however, maximum daily doses should not exceed 5 mg./Kg. (2.3 mg./lb.) where renal function is normal.

Not recommended against Proteus.

Colistin is also available (as colistin sulfate) in: Coly-Mycin® Pediatric for Oral Suspension (not for systemic use), and Coly-Mycin® Otic with Neomycin and Hydrocortisone.

Full information is available on request.

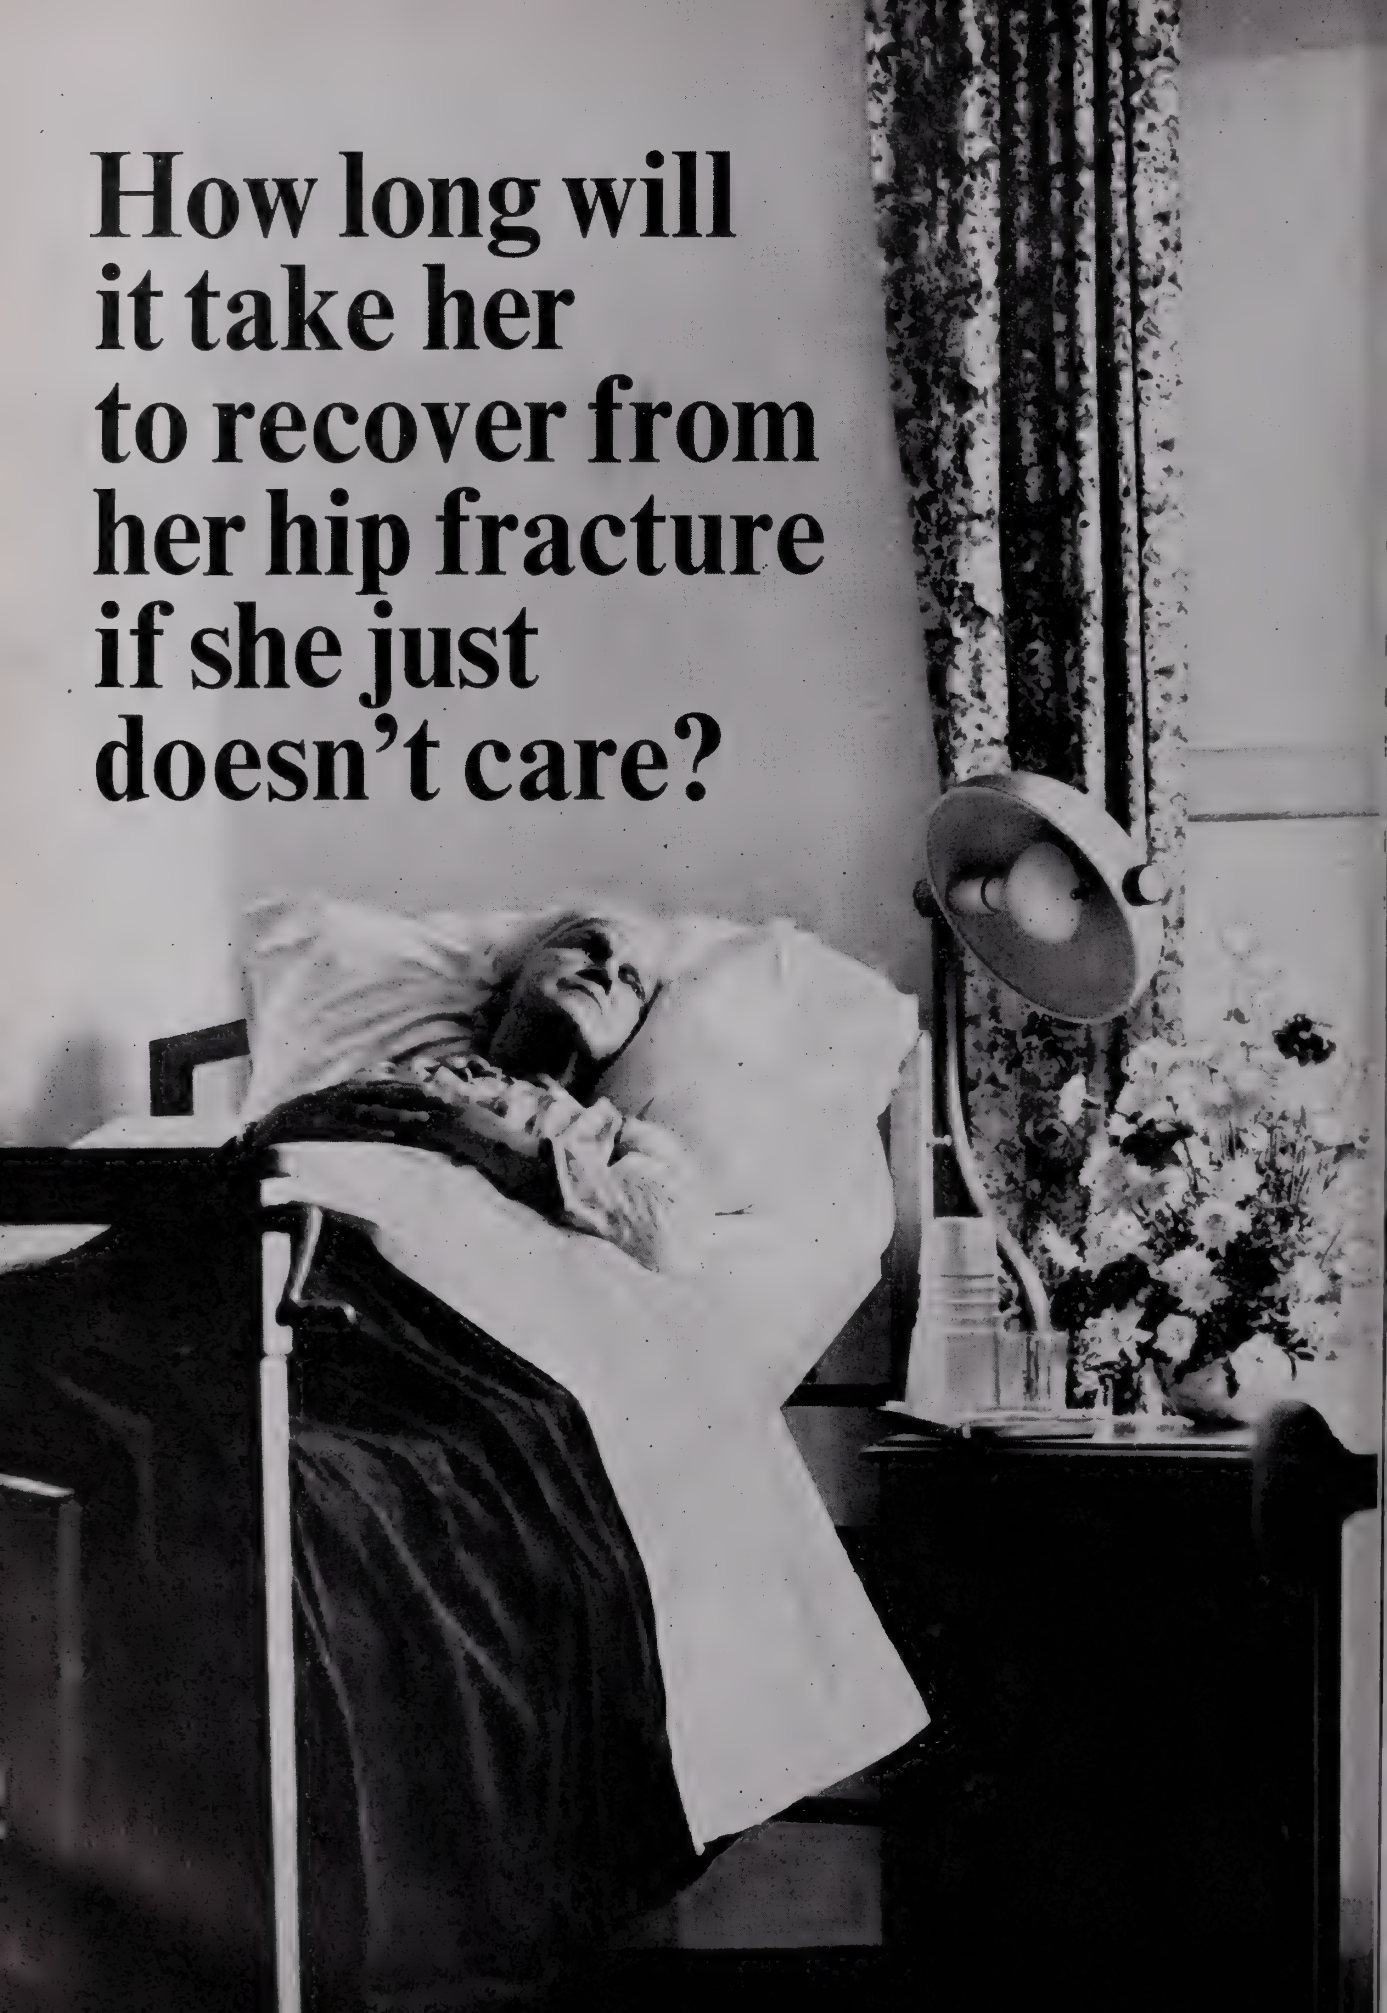
WARNER-CHILCOTT Morris Plains, New Jersey



How long will it take her to recover from her hip fracture if she just doesn't care?

**Does she really care?
Is she alert, encouraged, positive and optimistic about getting completely well soon?
Or has she given in to the demoralizing impact of confinement, disability and dependency?
When functional fatigue complicates convalescence, Alertonic can help...**

Pleasant-tasting Alertonic is pipradrol hydrochloride—an effective cerebral stimulant whose gentle analeptic action helps counteract the apathy and inertia that can often delay convalescence—together with an excellent vitamin and mineral formula, in a satisfying 15% alcohol vehicle.

Nothing fosters confidence and a sense of well-being better than your own personal warmth, understanding and encouragement together with Alertonic to help insure prompt response.

Adequate dosage is important: Prescribe Alertonic—one tablespoonful t.i.d., 30 minutes before meals...tastes best chilled.

And for your patient's sake, prescribe Alertonic in the convenient, economical one-pint bottle.

Alertonic®

Available Only On Prescription

Each 45 cc. (3 tablespoonfuls) contains: alcohol, 15%; pipradrol hydrochloride, 2 mg.; thiamine hydrochloride (vitamin B_1) (10 MDR*), 10 mg.; riboflavin (vitamin B_2) (4 MDR), 5 mg.; pyridoxine hydrochloride (vitamin B_6), 1 mg.; niacinamide (5 MDR), 50 mg.; choline,† 100 mg.; inositol,† 100 mg.; calcium glycerophosphate, 100 mg. (supplies 2% MDR for calcium and for phosphorus) and 1 mg. each of the following: cobalt (as chloride), manganese (as sulfate), magnesium (as acetate), zinc (as acetate), and molybdenum (as ammonium molybdate).

*Multiple of adult Minimum Daily Requirement supplied.
†The need for these substances in human nutrition has not been established.

Indications: 1. Functional fatigue such as that often associated with: a depressing life experience or stressful time of life; advancing years; convalescence; limited activity or confinement. 2. Poor appetite and vitamin-mineral deficiency as they occur in: patients having faulty eating habits; geriatric patients who are losing interest in food; patients convalescing from debilitating illness or surgery.

Dosage: Adults, 1 tablespoonful; children (over 15 years old), 1 to 2 teaspoonfuls; children (4 to 15 years old), 1 teaspoonful. To be taken three times daily 30 minutes before meals.

Contraindications: As with other drugs with CNS stimulating action, Alertonic is contraindicated in hyperactive, agitated or severely anxious patients and in chorea or obsessive compulsive states.

Side effects: Reports of overstimulation have been rare. Patients who are known to be unduly sensitive to the effects of stimulant drugs should be observed carefully in the initial stages of treatment.

FOR LEASE IN TWIN CITIES — small clinic, large parking area. With lease goes incredibly lucrative general practice, patients' records and excellent staff, at NO FEE. Write: MINNESOTA MEDICINE — 371; 496 Lowry Medical Arts Building, St. Paul 55102.

Tribute from a Scholar

Whilst I allow, that peculiar and important advantages arise from the appropriate studies of the three learned professions, I must confess, that in erudition, in science, and in habits of deep and comprehensive thinking, the pre-eminence must be assigned, in some degree, to physicians.

The most desirable profession is that of medicine; the practice of law spoils a man's moral sense and philosophic spirit; the Church is too bigoted and stiff-starched; but the study and practice of physic are equally favorable to a man's moral sentiments and intellectual faculties.

— Samuel Parr (1747-1825)

Thirtieth Annual Meeting
The New Orleans Graduate Medical Assembly

The thirtieth annual meeting of The New Orleans Graduate Medical Assembly will be held March 6, 7, 8, 9, 1967, headquarters at The Roosevelt Hotel.

Nineteen outstanding guest speakers will participate and their presentations will be of interest to both specialists and general practitioners. The program will include fifty-one informative discussions on many topics of current medical interest, in addition to clinicopathologic conferences, symposia, medical motion pictures, round-table luncheons and technical exhibits. This program is acceptable for thirty and one-half (30½) accredited hours by the American Academy of General Practice.

An interesting and enjoyable program of entertainment for visiting ladies has been planned.

For information concerning the Assembly meeting write Secretary, The New Orleans Graduate Medical Assembly, 1430 Tulane Avenue, Room 1528, New Orleans, Louisiana 70112.

Old Medical Equipment Needed

Minneapolis People to People are sponsoring a drive for used or repairable medical equipment and supplies which will be sent to Santiago, Chile, the Sister City of Minneapolis.

Doctors are asked to bring the material to the hospitals, which are serving as collection points. If the equipment is too large to be transported, please call Joe Paulson of the Jaycees at Swedish Hospital X-Ray department (333-4171) in Minneapolis.

Physician's Diary

If a civil word or two will render a man happy, he must be a wretch, indeed, who will not give them to him. Such a disposition is like lighting another man's candle by one's own, which loses none of its brilliancy by what the other gains. — Penn

The University of Minnesota has announced a new medical research project on the role of gastric and intestinal secretions in the regulation of iron absorption which will start at the University of Minnesota's College of Medical Sciences under the direction of **Dr. M. John Murray**, associate professor of medicine.

* * *

Dr. Bror F. Pearson, Shakopee physician, has volunteered under the AMA Volunteer Physicians for Vietnam program for a 60-day period of service in South Vietnamese civilian hospitals. He will leave for Vietnam in October.

* * *

Dr. M. J. Lindahl of Sherburn was recently featured on the cover of the August issue of the Assembly of God Church Magazine, "Team."

* * *

Dr. Laurentius O. Underdahl became president of the American Diabetes Association at its annual meeting in Chicago. Dr. Underdahl is associate professor of clinical medicine at the Mayo Graduate School of Medicine and head of a medical section at the Mayo Clinic.

* * *

Dr. L. R. Lima of Montevideo has been elected to active membership in the American Academy of General Practice, and **Dr. John E. Mathers** of Austin has been elected to membership in the American Board of Obstetrics and Gynecology.

* * *

Dr. Edith Parkhill, pathologist at the Mayo Clinic, retired from the Clinic in September. She will continue to live in Rochester.

* * *

Dr. Richard M. Magraw, University of Minnesota professor of psychiatry and medicine and director of the University's comprehensive clinic, received the 1966 Norman A. Welch, M.D., Memorial Award, for his book, "Ferment in Medicine." In presentation of the award it was noted that the judges felt, without dissent, that Dr. Magraw's book represented "the most scholarly and meritorious contribution to the literature of medical (care)" during the past year.

* * *

The following surgeons were inducted as new Fellows of the American College of Surgeons during its five-day Clinical Congress in San Francisco in October: **Dr. John L. Sander** of Cambridge, **Dr. Owen W. Holm** of Crookston, **Doctors Anderson C. Hilding, Don P. Swensen** and **John V. Thomas** of Duluth, **Doctors Clyde E. Blackard, Arndt J. Duvall III, Henry Gans, Stanley M. Goldberg** and **Howard M. Levine** of Minneapolis, **Doctors Lowell F. A. Peterson, Jack L. Pulec, Robert B. Wallace,** and **Tiffany J. Williams** of Rochester, **Doctors Frank T. Brown** and **Carl B. Thuringer** of St. Cloud, **Doctors John B. Brainard** and **Thomas L. Huseby** of St. Paul and **Dr. David E. Martin III** of Wabasha.

* * *

Dr. Russell L. Drake, head of the Section of Medical Illustration of the Mayo Clinic from 1932 to 1961, was awarded a special citation and certificate in honor of his contributions to the Association of Medical Illustrators at the 21st annual meeting of the organization in Atlanta, Georgia, in October.

* * *

Dr. C. Allen Good, head of the Section of Roentgenology of the Mayo Clinic, Rochester, and professor of radiology in the Mayo Graduate School of Medicine, was chosen president-elect of the American Roentgen Ray Society at its annual meeting at San Francisco in September.

* * *

Dr. E. Larry Kruger of Nashwauk was recently honored by that community on occasion of his tenth year anniversary as Nashwauk's physician.

* * *

Dr. Robert R. Kierland, head of the Section of Dermatology of the Mayo Clinic, was elected chairman of the Section on Dermatology of the American Medical Association at the 115th annual session of the organization in June.

Who'd hire mentally retarded people?

W. T. Grant Company
Terretts' Auto Laundry
DuBos' Furniture Repair
Remco Industries, Inc.
Youngblood's Fried Chicken Restaurant
The Hecht Company
Honolulu Laundry Company, Ltd.

You?

Whether you're the head of a big business like W. T. Grant Company or a small one like Youngblood's Fried Chicken Restaurant, you'd be smart to hire mentally retarded people. For they actually do some jobs better than people of average intelligence.

That's because they don't get bored by repetition or routine. They like to load trucks, tighten bolts on assembly line jobs, trim hedges, sort and deliver mail.

And since the retarded take pride in these jobs, they show up on time every day. They stick to the work until it's done. Then they're ready to start all over again the next day.

Right now, over two million mentally retarded people are employed by private companies and government agencies in many different kinds of jobs. They've worked out so well, many people are hiring more.

Think it over. And write for a free booklet to The President's Committee on Mental Retardation, Washington, D.C.

Minnesota Medicine at a Glance

Nerves to the Esophageal Hiatus — Wynyard & Kletschka Page 1821

A better understanding of the esophageal hiatus and its nerve supply might provide a better end result in the surgical repair of this relatively common defect.

The authors have indicated that injury to the terminal branches of the crural nerves can occur when the defect in the hiatus is closed posteriorly, because this is the position in which the nerves course in the musculature forming the crura. It has been shown that when these nerves are crushed, a corresponding area of the diaphragm undergoes atrophy.

Subcutaneous Injuries — Stark and Connelly Page 1825

It is not always necessary in injury that the skin be broken, and as Stark and Connelly have indicated in their case reports, the subcutaneous fat may be separated from the underlying fascia and the overlying skin, resulting in the accumulation of serosanguineous exudate or other tissue material, which in turn provides delay in healing and other associated complications.

They emphasize the importance of early recognition and prompt treatment in order to reduce the morbidity from this type of injury.

Tomography of the Respiratory Tract — Heitzman et al. Page 1829

The polytome makes it possible to visualize the pulmonary tract from many different angles. In the use of this machine the hypocycloidal motion above and below the plane of interest results in grayness of the surrounding tissue, but makes it possible to visualize a small lesion more clearly. After the lesion has been localized, then a thin hypocycloidal section can be made for detailed analysis.

These observations are illustrated in the accompanying photographs.

Acute Arterial Occlusion — Gregg Page 1835

The authors have presented their views regarding the proper management of acute arterial occlusion and have pointed out the importance of differentiating between acute venous thrombosis and acute arterial occlusion, stressing also the importance of evaluating the entire cardiovascular system so as to determine how much a poor cardiac output affects peripheral ischemia.

They also endeavor to determine the patient's ability to withstand surgery and anesthesia so as to be able to project how well his heart will function in the future if an operation is to be undertaken on the affected extremity.

Drive Safely

Nowadays drivers seldom sound their horns; Gabriel does it for them.

BOOK REVIEWS

A History of Pathology. Esmond R. Long 515
A Current Pediatric Therapy. S. S. Gellis and Benjamin Kagan 1917
A Primer of Water, Electrolyte and Acid Base Syndromes. Emanuel Goldberger 345
Anatomy and Surgical Technique of Groin Dissection. Shieber and Dillard 345
Applied Virology. Murray Sanders and Edwin Lennette 847
Cardiac Evaluation in Normal Infants. R. F. Ziegler 1307
Chest Film in Massive Pulmonary Embolism. D. J. Torrance, Jr. 515
Communicable and Infectious Diseases (no author) 847
Congenital Heart Disease — Correlation of Pathologic Anatomy and Angiocardiography. J. E. Edwards, L. S. Carey, H. N. Neufeld and R. G. Lester 169
Controversy in Internal Medicine. F. J. Ingelfinger, Arhold S. Relman and Maxwell Finland 1779
Correctable Renal Hypertension. Chester C. Winter 1007
Current Medical Terminology. Burgess L. Gordon 1179
Depressive States: A Pharmacotherapeutic Study. Anthony Hordern 681
Encyclopedia for Medical Assistants. Louis Brachman 1917
Ferment in Medicine: A Study of the Essence of Medical Practice and Its New Dilemmas. Richard M. Mcgraw 1621
Foundations of Anesthesiology. Albert Faulconer and Thomas E. Keys 1007
From Auscultation to Phonocardiography. Aldo A. Luisada 681
Heritable Disorders of Connective Tissue. Victor A. McKusick 1621
Mental Retardation: A Handbook for the Primary Physician (No author) 515
Modern Treatment (no author) 345
Neuro-Ophthalmology. J. L. Smith 847
Operable Heart Disease — Pathophysiology, Diagnosis and Treatment. Howard D. Sirak 1779
Pediatric Therapy. Harry S. Shirkey 1479 and 1917.
Peripheral Vascular Diseases. Travis Winsor and Chester Hyman 1479
Radiologic Diagnosis in Infants and Children. Armond E. Brodeur 1307
Resuscitation of the Newborn Infant and Related Emergency Procedures Principles and Practice (no author) 1779
Rypins' Medical Licensure Examinations. Arthur W. Wright 1179
Surgery of the Biliary Passages and Pancreas. Walter Hess 169
Surgery of the Foot. Henri L. DuVries 1307
Symposium on Cataracts (no author) 1007
Symposium on Surgery of the Ocular Adnexa 1917
Synopsis of Cardiology. W. I. Gefter, B. H. Pastor, R. M. Myerson 345
Therapeutic Radiology — Rationale, Technique, Results. William F. Moss 1479
Twins: Twice the Trouble, Twice the Fun. Betsy Holland Gehman 1621
Vitreoretinal Pathology and Surgery in Retinal Detachment. Paul A. Cibis 1179

C

Carcinoid Syndrome Circulatory and Cardiac Manifestations. Eldred G. Zobl, Leonard M. Kalfuss, Thomas C. Knechtges, Vishwanath M. Sardesai 39
Carcinoma, Thyroid — Unusual Clinical Features and Problems of Management. Alexander J. Walt 32
Cardioversion of Ventricular Tachycardia Following Myocardial Infarction. Hans Aberg and Donald B. Swenson 403
Carlson, R. G. and Glas, W. W.: Congenital Cystic Dilatation of the Common Bile Duct — Preoperative Diagnosis by Intravenous Cholangiogram 429
Carotid Artery — Surgery for the Totally Occluded Extracranial Internal. Joseph J. Garamella, Michael F. Lynch, Nathan Kenneth Jensen, Laurence P. Sterns and W. Robert Schmidt 1669
Case for Body Surface Area As A Gauge for Drug Dosage. W. D. Snively, Jr. 1521
Cerebral Vasospasm 1965. L. M. Thomas, G. P. Scratch, E. S. Gurdjian 55
Cervix, Incompetent. William B. Stromme, Robert M. Wagner, E. William Haywa 393
Chason, J. L., Mahoney, William F., Landers, James W.: Massive Intracerebral Hemorrhage 37

C (Continued)

Cholecystitis, Acute, Due to Coagulase Positive Staphylococci. Claude V. DeShazo, Robert P. Belin, Judson F. Lloyd, Arnold I. Walder 409

Cholesterol Synthesis, Human Serum. C. Bruce Taylor, B. Mikkelson, J. A. Anderson, D. T. Forman, Gary Franz 728

Chronic Obstructive Airway Disease — Improvement in Pulmonary Function after Vigorous Program. David E. Dines 1089

Chronic Ulcerative Colitis in Children — Reevaluation of Management. Hugh B. Lynn 417

Clomiphene, The Anovulatory Syndrome Treated with. W. N. Spellacy and W. D. Cohen 1357

Cohen, Alberto, Lubs, Eide-Ditmar, Zaleski, Edward J., Bing, Richard J.: A New Diagnostic Test for Coronary Artery Disease — Using A Coincidence Counting System 17

Cohen, Sumner S. and Yue, Wen Y.: Pulmonary Nocardiosis — Report of Two Cases 1077

Cohen, W. D. and Spellacy, W. N.: The Anovulatory Syndrome Treated with Clomiphene 1357

Colitis, Chronic Ulcerative, in Children — Reevaluation of Management. Hugh B. Lynn 417

Colitis, Nonspecific Ulcerative — Puerperal Disseminated Intravascular Coagulation as a Complication. M. H. Short, J. Burns, C. Brown, J. Brainard, J. Teisberg 1691

Collen, Morris F.: Computer Medicine Its Application Today and Tomorrow 1705

Common Bile Duct, Congenital Cystic Dilatation of the — Preoperative Diagnosis by Intravenous Cholangiogram. R. G. Carlson and W. W. Glas 429

Communication Barriers between Medical Students and Their Psychiatric Patients. Adeline U. Mandel, Sherod L. Miller, Floyd K. Garetz 915

Computer Medicine — Its Application Today and Tomorrow. Morris F. Collen 1705

Congenital Cystic Dilatation of the Common Bile Duct — Preoperative Diagnosis by Intravenous Cholangiogram. R. G. Carlson and W. W. Glas 429

Congenital Hip Subluxation and Dislocation in Early Infancy — Management of. Ramon B. Gustilo, Richard Cushing, Arnold S. Anderson 892

Congenital Nonspherocytic Hemolytic Disease with Erythrocyte Glucose-6-Phosphate Dehydrogenase Deficiency. Irving Lerner and Alfred Doscherholmen 1387

Connelly, David M. and Stark, David B.: Shearing Injuries of the Subcutaneous Tissues 1825

Conventional Scanning vs. Scintillation Camera — A Comparison for Evaluation of Brain Pathology. Merle K. Loken, Gerald Telander, Stefan Laxdal 237

Cooley, Denton A., Yonehiro, Earl G., Hallman, Grady L.: Partial Anomalous Pulmonary Venous Return — A Hypoplastic Right Lung to the Inferior Vena Cava (Scimitar Syndrome) 1243

Cooney, Marion K., St. Geme, Joseph W., Jr., Wedemeyer, Phillips P.: Echovirus Type 18 Infection — An Unusual Exanthem 1057

Cooper, Max D., Peterson, Raymond D. A., Finstad, Joanne, Good, Robert A., Gabrielsen, Ann E.: Immunogenesis, Leukemogenesis and Experimental Auto-Immunity 725

Coronary Artery Disease, A New Diagnostic Test for — Using a Coincidence Counting System. Alberto Cohen, Eide-Ditmar Lubs, Edward J. Zaleski, and Richard J. Bing 17

Coumarin-Induced Bleeding Complications — Report of Eight Unusual Cases from One Hospital. Richard L. Reece and Philip A. Olson 1677

Crural Branches of the Phrenic Nerves — Their Surgical Significance. Martin Wynyard and Harold D. Kletschka 1821

Cushing, Richard, Anderson, Arnold S., Gustilo, Ramon B.: Congenital Hip Subluxation and Dislocation in Early Infancy — Management of 892

Cyclophosphamide, Acute Myeloid Leukemia — Treatment of with 6-Mercaptopurine and. B. J. Kennedy, John W. Yarbro, Richard S. Kronenberg 1071

Cystic, Congenital, Dilatation of the Common Bile Duct — Preoperative Diagnosis by Intravenous Cholangiogram. R. G. Carlson and W. W. Glas 429

Blood-glucose screening for all your patients?

...because "Abnormalities of glucose metabolism are among the [most common] encountered in clinical practice...."* Simple, quick, economical blood-glucose screening with DEXTROSTIX® Reagent Strips is practicable in every regular physical examination, emergency situation, and whenever hypo- or hyperglycemia may be of clinical significance—for "The precision and accuracy of DEXTROSTIX ...meet the need for an always available simple screening method...."* All that is required for screening with DEXTROSTIX is 60 seconds and a globular drop of capillary or venous blood. Abnormal readings will be a valuable aid to diagnosis; normals will help you establish an important baseline for future reference.

Marks, V., and Dawson, A.: Brit. M. J. *1*:293, 1965.

DEXTROSTIX—
provides a clinically useful determination when performed according to directions†

DEXTROSTIX is not intended to replace the more precise analytical laboratory methods.

when **anxiety** is part of the clinical picture

Librium®

(chlordiazepoxide HCl)

In prescribing: Dosage — Adults: Mild to moderate anxiety and tension, 5 or 10 mg t.i.d. or q.i.d.; severe states, 20 or 25 mg t.i.d. or q.i.d. Geriatric patients: 5 mg b.i.d. to q.i.d.

Side Effects: Side effects, usually dose-related, include drowsiness, ataxia, minor skin rashes, edema, menstrual irregularities, nausea and constipation. When treatment is protracted, blood counts and liver function tests are advisable. Paradoxical reactions may occasionally occur in psychiatric patients. Individual maintenance dosages should be determined.

Precautions: Advise patients against possibly hazardous procedures until maintenance dosage is established. Though compatible with most drugs, use care in combining with other psychotropics, particularly MAO inhibitors or phenothiazines; warn patients of possible combined effects with alcohol. Observe usual precautions in impaired renal or hepatic function, in long-term treatment and in presence of depression or suicidal tendencies. Exercise caution in administering drug to addiction-prone patients or those who might increase dosage; withdrawal symptoms, similar to those seen with barbiturates or meprobamate, can occur upon abrupt cessation after prolonged overdosage. Caution should be exercised in prescribing any therapeutic agent for pregnant patients.

Supplied: Capsules, 5 mg, 10 mg and 25 mg, bottles of 50.

new from Ames 5 basic uro-analytical facts in 30 seconds

Labstix®

BRAND REAGENT STRIPS

...broadest urine screening possible from a single reagent strip

Urine test results with Labstix Reagent Strips can represent significant guides to differential diagnosis or therapy in many conditions. An unexpected "positive" may enable you to detect hidden pathology—long before more recognizable symptoms become evident. Negative results, which permit you to rule out abnormalities in a broad clinical range, can serve as baseline values for reference in future examinations. The 5 colorimetric test areas encompassed on Labstix Reagent Strips are:

pH—values are read numerically in the essential range of pH 5 to pH 9.

Protein—results are read either in the "plus" system or in mg. % in amounts approximating "trace," 30, 100, 300, and over 1000 mg. %.

Glucose—provides a "Yes-or-No" answer for urine "sugar spill."

Ketones—detects ketone bodies in urine—**both** acetoacetic acid and acetone. Reacts with as little as 5 to 10 mg. % of acetoacetic acid.

Occult Blood—specific test for intact red cells, hemoglobin or myoglobin. Results are read as negative, small, moderate or large amounts.

Now a Clear Reagent Strip of Firm Construction

...facilitates handling during testing procedure. Excellent color contrast made possible by the clear plastic strip, together with the clearly defined color charts provided, permits precise, reproducible colorimetric readings in all 5 test areas. A more definitive interpretation of uro-analytical facts is made possible.

Available: Labstix Reagent Strips, bottles of 100 (color charts are supplied with each bottle).

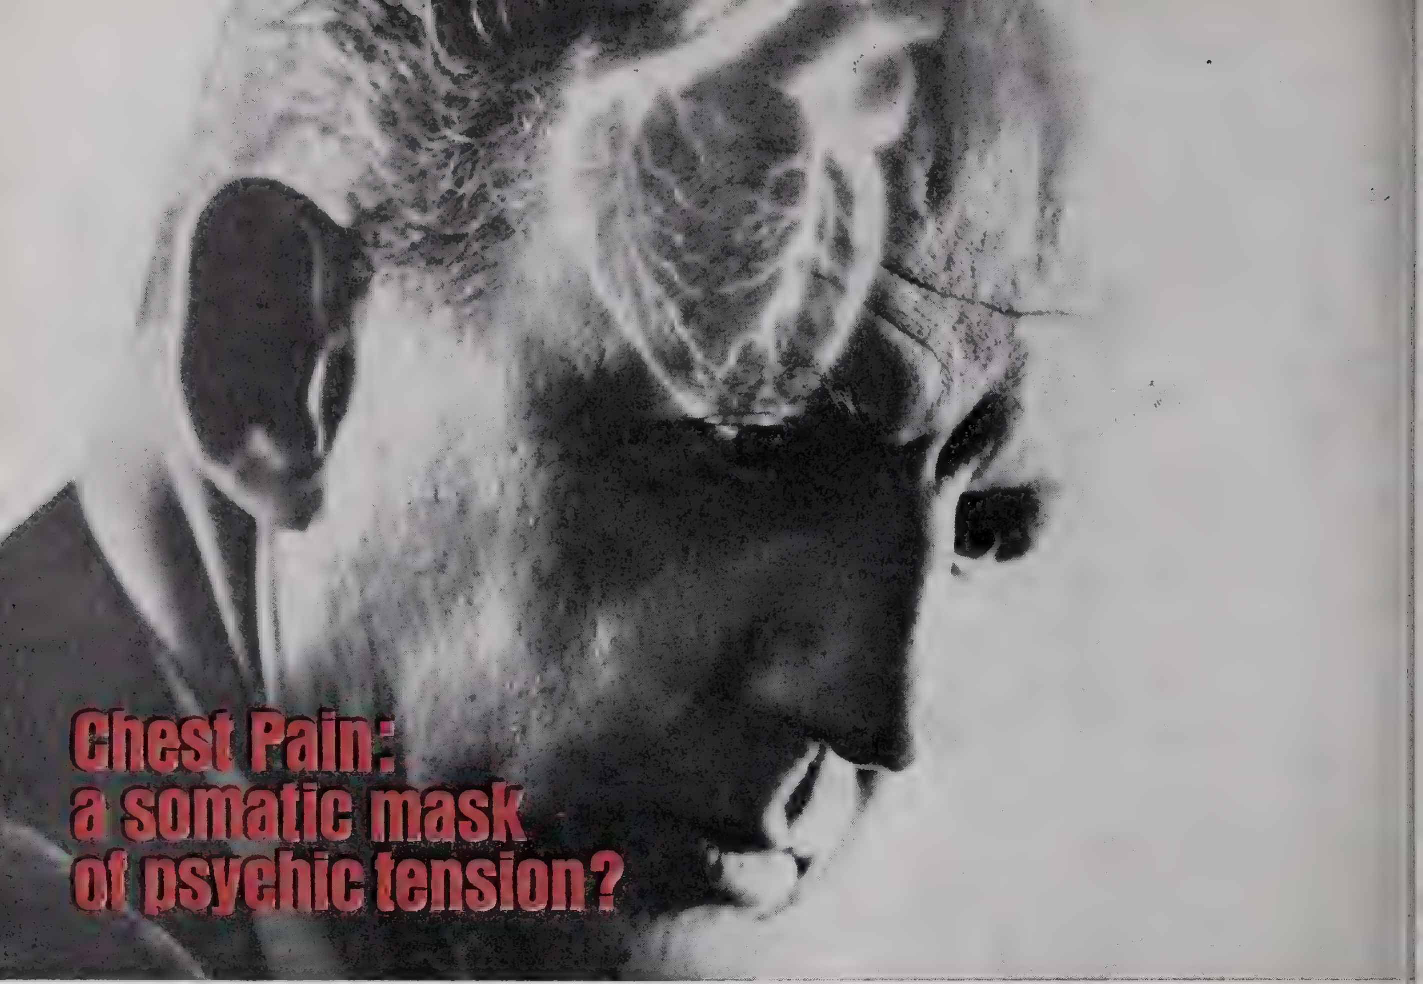
AMES

08169



"Heart symptoms"—chest pain, tachycardia, arrhythmia—invariably alarm and preoccupy the patient, though they may be completely without organic basis. Such symptoms often are somatic masks of psychic tension, arising from constant encounters with stressful situations.

When the problem is diagnosed as emotionally produced, consider Valium (diazepam) as adjunctive therapy. Valium (diazepam) acts rapidly to calm the patient, to reduce his psychic tension and relieve associated cardiovascular complaints.

NEUROTIC FATIGUE—the chronic tiredness resulting from emotional strain which so often accompanies psychogenic "heart" symptoms—also can be alleviated by this highly useful agent. Valium (diazepam) often achieves results where other psychotherapeutic agents have failed.

Valium (diazepam) is generally well tolerated, and usually does not impair mental acuity or ability to function. If side effects such as ataxia and drowsiness occur, they usually disappear with dosage adjustment.

Contraindications: Infants, patients with history of convulsive disorders or glaucoma.

Warning: Not of value in the treatment of psychotic patients, and should not be employed in lieu of appropriate treatment.

Precautions: Limit dosage to smallest effective amount in elderly patients (not more than 1 mg, one or two times daily) to preclude ataxia or oversedation. Advise patients against possibly hazardous procedures until correct maintenance dosage is established; driving during therapy not recommended. In general, concurrent use with other psychotropic agents is not recommended. Warn patients of possible combined effects with alcohol. Safe use in pregnancy not established. Observe usual precautions in impaired renal or hepatic function and in patients who may be suicidal; periodic blood counts and liver function tests advisable in long-term use. Cease therapy gradually.

Side Effects: Side effects (usually dose-related) are fatigue, drowsiness and ataxia. Also reported: mild nausea, dizziness, blurred vision, diplopia, headache, incontinence, slurred speech, tremor and skin rash; paradoxical reactions (excitement, depression, stimulation, sleep disturbances and hallucinations) and changes in EEG patterns. Abrupt cessation after prolonged overdosage may produce withdrawal symptoms similar to those seen with barbiturates, meprobamate and chlordiazepoxide HCl.

Dosage — Adults: Mild to moderate psychoneurotic reactions, 2 to 5 mg b.i.d. or t.i.d.; severe psychoneurotic reactions, 5 to 10 mg t.i.d. or q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hrs, then 5 mg t.i.d. or q.i.d. as needed; muscle spasm with cerebral palsy or athetosis, 2 to 10 mg t.i.d. or q.i.d. Geriatric patients: 1 or 2 mg/day initially, increase gradually as needed.

Supplied: Tablets, 2 mg, 5 mg and 10 mg; bottles of 50 for convenience and economy in prescribing.
